<ul style="list-style-type: none"> Enjaymo™ (Sutimlimab-Jome)

Application

This Medical Benefit Drug Policy does not apply to the states listed below; refer to the state-specific policy/guideline, if noted:

State	Policy/Guideline
Florida	Refer to the state’s Medicaid clinical policy
Indiana	Enjaymo™ (Sutimlimab-Jome) (for Indiana Only)
Kansas	None
Louisiana	None
North Carolina	None

Coverage Rationale

Enjaymo is medically necessary for the treatment of CAD in patients who meet all of the following criteria:

- For initial therapy, all of the following:
 - Diagnosis of CAD by, or in consultation with, a hematologist with expertise in the diagnosis of CAD; and
 - Confirmation of the CAD diagnosis based on all of the following:
 - Evidence of chronic hemolysis (e.g., elevated lactated dehydrogenase [LDH], decreased haptoglobin, increased indirect bilirubin, increased reticulocyte count); and
 - Positive polyspecific direct antiglobin test (DAT); and
 - Positive monospecific DAT specific for C3d; and
 - Immunoglobulin G (IgG) DAT ≤ 1+; and
 - Cold agglutinin titer ≥ 64 at 4°C
 - and
 - Cold agglutinin syndrome secondary to other factors has been ruled out (e.g., infection, rheumatologic disease, systemic lupus erythematosus, overt hematologic malignancy, other autoimmune disorders); and
 - Patient has a baseline hemoglobin level ≤ 10 g/dL; and
 - Enjaymo is prescribed by a hematologist; and
 - Enjaymo dosing is in accordance with the United States Food and Drug Administration approved labeling; and

- Patient is not receiving Enjaymo in combination with a complement inhibitor [e.g., Soliris (eculizumab), Ultomiris (ravilizumab-cwzb), Empaveli (pegcetacoplan)]; and
- Initial authorization will be for no more than 6 months.
- For continuation of therapy, all of the following:
 - Documentation of positive clinical response to therapy (e.g., increase in hemoglobin, decreased transfusion requirements, decreased markers of hemolysis, improvement in anemia-related symptoms); and
 - Enjaymo is prescribed by, or in consultation with, a hematologist; and
 - Enjaymo dosing is in accordance with the United States Food and Drug Administration approved labeling; and
 - Patient is not receiving Enjaymo in combination with a complement inhibitor [e.g., Soliris (eculizumab), Ultomiris (ravilizumab-cwzb), Empaveli (pegcetacoplan)]; and
 - Reauthorization will be for no more than 12 months.

Requests outside of this criteria will be reviewed for medical necessity on a case by case basis.

Applicable Codes

The following list(s) of procedure and/or diagnosis codes is provided for reference purposes only and may not be all inclusive. Listing of a code in this policy does not imply that the service described by the code is a covered or non-covered health service. Benefit coverage for health services is determined by federal, state, or contractual requirements and applicable laws that may require coverage for a specific service. The inclusion of a code does not imply any right to reimbursement or guarantee claim payment. Other Policies and Guidelines may apply.

HCPCS Code	Description
C9094	Injection, sutimlimab-jome, 10 mg
J3590	Unclassified biologics

Diagnosis Code	Description
D59.12	Cold autoimmune hemolytic anemia

Background

Cold agglutinin disease (CAD) is a form of autoimmune hemolytic anemia (AIHA) in which cold agglutinins can cause clinical symptoms related to agglutination of red blood cells in cooler parts of the body and hemolytic anemia. Primary chronic cold (hem)agglutinin disease accounts for about 15-25% of AIHAs. CAD is defined as an AIHA mediated by cold agglutinins (CAs), without any obvious underlying disease such as aggressive lymphoma, other overt malignancies, or specific infections. CAs are autoantibodies that are able to agglutinate red blood cells (RBCs) at an optimum temperature of 3-4°C, but can also react at higher temperatures, depending on the thermal amplitude.

Hemolysis in CAD is primarily extravascular and mediated by complement. The IgM cold agglutinin binds to an antigen on the surface of RBCs in sites of the body where the temperature is low enough to be in the thermal range of the antibody. The bound IgM recruits components of the classical pathway of complement, such as C1, C4, and C2. C1-esterase activates C4 and C2, leading to production of the C3 convertase, which cleaves C3 to C3a and C3b. Lastly, C3b-coated RBCs undergo extravascular hemolysis due to phagocytosis by macrophages in the liver.

Clinical Evidence

An International Consensus Group published recommendations in 2019 on the diagnostic and therapeutic approach for autoimmune hemolytic anemias, including cold agglutinin disease (CAD). Diagnostic recommendations for CAD include markers of chronic hemolysis accompanied by a direct antiglobin test (DAT, direct “Coombs test”) for C3d, with a cold agglutinin (CA) titer of 64 or greater at 4°C. Treatment recommendations included watchful waiting in patients with hemoglobin levels > 10 g/dL unless comorbid ischemic cardiac disease or chronic obstructive pulmonary disease was present with blood transfusions recommended when indicated. Recommended treatment goals included improvement in hemoglobin levels and improvement in symptoms. Rituximab monotherapy was a recommended first-line therapy for those requiring chronic treatment

as response rates of 50% have been reported in uncontrolled trials. Alternative first and second-line recommendations include rituximab combined with bendamustine or fludarabine. A 71% response rate has been reported with rituximab plus bendamustine combination therapy, with 40% achieving complete response (CR) and 31% partial response (PR). Hemoglobin levels increased by a median of 4.4 g/dL in the complete responders and 3.9 g/dL in those who had a PR. Median time to response was 1.9 months, and less than 10% of the responders had relapsed at 32 months. A 76% response rate has been reported with rituximab plus fludarabine combination therapy, with 21% achieving CR and 55% achieving PR. Median increase in Hb level was 3.1 g/dL in the responders and 4.0 g/dL among those who achieved CR. Median time to response was 4.0 months, and estimated median response duration was more than 66 months.

Sutimlimab was studied in a 26-week open-label, single-arm, multicenter phase 3 CARDINAL study (Part A) with a 2-year extension phase (Part B). Patients with a confirmed diagnosis of CAD based on chronic hemolysis, polyspecific DAT, monospecific DAT specific for C3d, cold agglutinin titer ≥ 64 at 4°C, and IgG DAT $\leq 1+$ were enrolled. Eligibility criteria included baseline hemoglobin (Hb) ≤ 10 g/dL, total bilirubin level above normal, and ≥ 1 blood transfusion in the prior 6 months. Sutimlimab was administered intravenously on Days 0 and 7, followed by biweekly infusions. Patients weighing < 75 kg or ≥ 75 kg received a 6.5 g or 7.5 g dose, respectively. The primary efficacy endpoint was response rate based on a composite of Hb increase ≥ 2 g/dL or Hb ≥ 12 g/dL at treatment assessment and transfusion avoidance from Weeks 5 to 26. Secondary efficacy endpoints included change from baseline in hemolytic markers (e.g., bilirubin) and quality of life (QOL) measured by the Functional Assessment of Chronic Illness Therapy Fatigue (FACIT-F) Scale.

Twenty-four patients enrolled and received ≥ 1 dose of sutimlimab. The mean (standard deviation) age was 71.3 (8.2) years with 62.5% females. Mean (range) baseline Hb was 8.6 (4.9-11.1) g/dL. The median (range) number of transfusions within 6 months prior to enrollment was 2 (1-19) and 62.5% of patients had failed prior therapies. Out of 24 patients, 22 completed Part A; 2 patients were withdrawn early for reasons unrelated to the study drug. The prespecified primary endpoint was met in 13 (54.2%) patients. The estimated mean Hb increase at treatment assessment time point was 3.2 g/dL. Hb improved rapidly after the first dose of sutimlimab with 1.2 g/dL and 2.3 g/dL increases by Weeks 1 and 3, respectively. Mean overall Hb was maintained above 11 g/dL after Week 3. Twenty (83.3%) patients had a Hb increase ≥ 1 g/dL. Fifteen (63%) patients had a Hb increase ≥ 2 g/dL. Nine (38%) of patients had a Hb level of ≥ 12 g/dL. Mean total bilirubin was normalized by Week 3. Seventeen (70.8%) patients remained free of transfusions from Weeks 5 to 26. FACIT-F scores improved within 1 week, peaking by Week 5, and remained stable through Week 26.

Interim results of the Part B extension phase have been reported at 1-year follow-up. The primary objectives of the interim Part B analysis are to evaluate long-term safety and tolerability of sutimlimab for ≥ 53 weeks; secondary objectives are to investigate the durability of response over time. Efficacy endpoints included change from baseline in hemolytic markers and the patient-reported outcome: Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) Scale. All patients who completed Part A entered Part B. Hb improved rapidly after first sutimlimab dose and mean Hb was > 11 g/dL from Week 5 to Week 53. Mean total bilirubin was normalized by Week 3 and remained < 20 $\mu\text{mol/L}$ to Week 53. Normalization of mean absolute reticulocyte count was observed alongside normalized haptoglobin levels and reductions in lactate dehydrogenase. Seventeen (70.8%) and 19 (86.4%) patients remained transfusion-free from Week 5 to Week 26 and Week 26 to Week 53, respectively. From baseline to Week 53, all 24 patients experienced ≥ 1 treatment-emergent adverse event (TEAE); 12 (50.0%) patients experienced a serious TEAE. One serious TEAE (viral infection) was associated with sutimlimab. Serious (including bacterial) infections were reported, but no meningococcal infections were identified. There was 1 TEAE of device-related thrombosis (assessed as unrelated to study drug) in Part B; there were no other vascular thromboembolic TEAEs. One patient died due to a progressive carcinoma (unrelated to study drug).

U.S. Food and Drug Administration (FDA)

This section is to be used for informational purposes only. FDA approval alone is not a basis for coverage.

Enjaymo is a classical complement inhibitor indicated to decrease the need for red blood cell (RBC) transfusion due to hemolysis in adults with cold agglutinin disease (CAD).
