Clinical Information to Establish Medical Necessity Guideline

AD.CI.MN
v1.1.2026

The clinical guidelines apply an evidence-based approach to evaluate the most appropriate medically necessary care for each individual. This evaluation requires submission of legible medical records pertinent to the test or treatment being requested by the provider.

If the medical records provided do not provide sufficiently detailed information to understand the individual's current clinical status or cannot be read, then medical necessity for the request cannot be established and cannot be approved.

Specific elements of an individual's medical records commonly required to establish medical necessity include, but are not limited to:

- Virtual or in-person clinical evaluation which includes a detailed history and physical examination since the onset or change in symptoms
- Laboratory studies
- Imaging studies
- Pathology reports
- Procedure reports
- Reports from other providers participating in treatment of the relevant condition

Medicaid and Medicare Hierarchy and Application

CMS.AD.100.A
v2.0.2026

Medicaid

Medicaid Hierarchy

1. Medicaid state-specific policy
2. The evidence-based guidelines or the appropriate alternative guideline utilized by a program/health plan in place of these guidelines
3. Early and Periodic Screening, Diagnostic and Treatment (EPSDT) guidelines should also be reviewed for individuals under 21 years of age as applicable for coverage determination

Application of Medicaid Policy

The state Medicaid policy will be reviewed first to determine if the information provided is instructive to the clinical case at hand. For the purpose of this policy, sufficient clinical criteria to render a medical necessity decision is defined as the presence of a state Medicaid policy that addresses the service/procedure/test/equipment and the member condition (indication) and supplies sufficient clinically relevant detail to be instructive to the case. See the numbered items below for specific guidance:

1. State Medicaid policy addresses clinical scenario: (service/procedure/test/equipment AND member condition AND Medical Necessity criteria):
   a. Medicaid policy will be utilized and cited for determining medical necessity
   b. If specific medical necessity criteria are present in the state policy, but are limited or less detailed than eviCore or alternative guideline, the state policy would still be applied and cited, as this would be considered sufficient information to render a decision
2. State policy exists for service/procedure/test/equipment AND member condition but NO medical necessity criteria exist for this indication. The state policy would still be instructive to the case clinical scenario and Medicaid policy will be utilized and cited.
3. State Medicaid policy addresses service/procedure/test/equipment, but does NOT cover member condition in question or provide specific medical necessity criteria for this indication and does not contain relevant clinical information to be instructive to the case/clinical scenario, eviCore guidelines or alternative guidelines, as appropriate, will be utilized and cited

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

a. (Example: Service is requested to address a member condition and the state policy indicates that the service is indicated for this member condition without providing specific criteria regarding under which circumstances the service would be indicated for this condition. This is considered instructive, and the state policy would be applied/cited.)

4. If no clinical information is provided with a request, the above hierarchy is still applied. If there is an applicable state-specific Medicaid policy, the Medicaid policy would be utilized and cited to request clinical information/documentation. If there is no applicable state-specific Medicaid policy, eviCore guidelines or alternative guidelines, as appropriate, will be utilized and cited

Note: The scope of this policy is to outline the default order in which policy sources will be used during a delegated medical necessity determination. The Medicaid hierarchy outlined here may be superseded by Plan- and State-specific Hierarchy policies, where applicable, based on contracts with a state Medicaid entity.

Application and citation of policy

Medicare Policy

CMS Coverage Hierarchy: Medicare Advantage Medical Policy Development and Application

Medicare Advantage medical policies identify the clinical criteria for determining when medical services are considered 'reasonable and necessary' (medically necessary). Medicare Advantage plans are required by CMS to provide the same medical benefits to Medicare Advantage members as original Medicare.

Medicare Advantage plans must comply with national coverage determinations (NCD), local coverage determinations (LCD), and general coverage and benefit conditions included in traditional Medicare laws. This includes criteria for determining whether an item or service is a benefit available under traditional Medicare. When coverage criteria are not fully established in Medicare statute, regulation, NCD, or LCD, Medicare Advantage organizations may create publicly accessible internal coverage criteria that are based on current evidence in widely used treatment guidelines or clinical literature.

If additional criteria are needed to interpret or supplement generalized provisions within an NCD, LCD or other Medicare coverage policy, or there is flexibility allowed in the NCD/LCD, or there is no applicable NCD, LCD, or LCA (used in concert with an LCD) available to determine medical necessity, then other evidence-based criteria may be applied.

Coverage criteria are not fully established when (42 CFR 422.101(6) (i) :

(i) Coverage criteria not fully established. Coverage criteria are not fully established when:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

(A) Additional, unspecified criteria are needed to interpret or supplement general provisions in order to determine medical necessity consistently. The MA organization must demonstrate that the additional criteria provide clinical benefits that are highly likely to outweigh any clinical harms, including from delayed or decreased access to items or services;

(B) NCDs or LCDs include flexibility that explicitly allows for coverage in circumstances beyond the specific indications that are listed in an NCD or LCD; or

(C) There is an absence of any applicable Medicare statutes, regulations, NCDs or LCDs setting forth coverage criteria.

The following hierarchy is used to determine Medicare Advantage Medical Policy:

1. CMS Coverage Manuals or other CMS-Based Resource: Coverage provisions in interpretive manuals are instructions that are used to further define when and under what circumstances items or services may be covered (or not covered)
2. National Coverage Determinations (NCD)
3. Local Coverage Determinations (LCD)
4. Local Coverage Articles (LCA) may be used in conjunction with LCDs, or if the LCA is stated as 'Not an LCD reference article' within the LCD , the LCA may be cited alone.
5. EviCore's evidence-based guidelines or the appropriate alternative guideline utilized by a program/health plan in place of EviCore's guidelines.

- Rationale supporting the adoption and use of internally developed coverage guidelines: When coverage criteria are not fully established (as defined in 42 CFR 422.101(6) (i)) in Medicare policy, an NCD, or an LCD, CMS allows a Medicare Advantage Organization (MAO) to create and use internally developed coverage criteria. See 'Coverage criteria are not fully established when (42 CFR 422.101(6) (i) above on page 3 for the full definition of 'not fully established'.
- NCDs with Coverage with Evidence Development (CED) contain fully established Medicare coverage criteria for purpose of 42 CFR § 422.101(b)(6). Therefore, Medicare does not permit MA organizations to apply internal coverage criteria to limit, expand, or modify the scope of the NCD with CED (42 CFR § 422.101(b)(6), November 25, 2025).
- EviCore will exhaust all traditional Medicare policies, NCDs, and LCDs prior to using internal criteria policies. When an internally created coverage policy is utilized for a specific condition where a Medicare policy, an NCD, or LCD is not fully established, the general provisions supplemented by the internal criteria will include when the specific clinical presentation of the enrollee, for the request under review is not addressed in the Medicare coverage policy; or there are no specific coverage criteria included in a Medicare policy because the policy provides broad provisions, which may be instructive, but are not detailed enough to be used to determine the medical necessity of the request. Additionally, internal coverage policy may be used when

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Medicare policy includes statements within the policy that allow for coverage beyond what is written in the Medicare policy.

- Under the guidance outlined above EviCore's evidence-based guidelines or the appropriate alternative guideline utilized by a program/health plan in place of EviCore's guidelines, EviCore may apply internally developed clinical coverage guidelines to the request under review. Each EviCore clinical coverage policy is developed following an objective, evidence-based process based on scientific evidence, generally accepted and current standards of medical practice, and authoritative clinical practice guidelines. Each coverage policy developed and used outlines clinical benefits, addresses any clinical harm, and access to services. In addition, each member's unique clinical situation is considered in conjunction with current CMS guidelines and EviCore clinical coverage policy, as applicable.

Note: Where a Medicare Administrative Contractor (MAC) has adopted the Palmetto GBA MolDX® Program's criteria for the LCDs governing molecular and genomic tests within their jurisdiction, EviCore's Laboratory Management program will follow the MolDX criteria published by the MACs for those jurisdictions.

Medicare/Medicaid Dual Membership

Hierarchy and Application for dual eligible Medicare/Medicaid

Individuals enrolled in both Medicare and Medicaid are considered to be dually eligible. For individuals with both Medicare and Medicaid, the following hierarchy should be applied.

1. CMS Coverage Manuals
2. National Coverage Determinations (NCD)
3. Local Coverage Determinations (LCD)
4. Local Coverage Articles (LCA) – when used in conjunction with an LCD
5. Evidence based clinical policies (EviCore) or the appropriate alternative guideline utilized by a program/health plan in place of EviCore's guidelines

Guideline Definitions

v1.0.2025

Experimental, Investigational, or Unproven

Certain studies, treatments, procedures, or devices may be considered experimental, investigational, or unproven for **any** condition, illness, disease, injury being treated if one of the following is present:

- if there is a paucity of supporting evidence;
- if the evidence has not matured to exhibit improved health parameters;
- if clinical utility has not been demonstrated in any condition; OR
- the study, treatment, procedure, or device lacks a collective opinion of support.

Supporting evidence includes standards that are based on credible scientific evidence published in peer-reviewed medical literature (such as well conducted randomized clinical trials or cohort studies with a sample size of sufficient statistical power) generally recognized by the relevant medical community. Collective opinion of support includes physician specialty society recommendations and the views of physicians practicing in relevant clinical areas when physician specialty society recommendations are not available.

Medically Necessary

Healthcare services or supplies needed to diagnose, treat, or evaluate a condition or prevent an injury, illness, condition or disease that meets accepted standards of medicine based on evidenced-based clinical standards of care based on supporting evidence and/or collective opinion of support that is:

- Clinically appropriate in terms of type, frequency, extent, site, and duration, and considered effective for the individual's illness, injury or disease;
- Clinical utility of the technology, drug, device, treatment or procedure has been demonstrated for a diagnosis, treatment, evaluation or prevention of an illness, condition or disease based on evidence-based clinical standards of care;
- Not more costly than an alternative service or sequence of services that are at least as likely to produce equivalent therapeutic or diagnostic results as to the diagnosis or treatment of a condition;
- Not primarily for the convenience of the individual seeking medical services, health care provider, or other physicians or healthcare providers;
- Supporting evidence and/or collective opinion of support does not demonstrate that there is an alternative that is more appropriate/effective for diagnosis, treatment, or evaluation of a condition.

Proprietary Information of UnitedHealthcare.

Supporting evidence includes standards that are based on credible scientific evidence published in peer-reviewed medical literature (such as well conducted randomized clinical trials or cohort studies with a sample size of sufficient statistical power) generally recognized by the relevant medical community. Collective opinion of support includes physician specialty society recommendations and the views of physicians practicing in relevant clinical areas when physician specialty society recommendations are not available. Determination of medical necessity is based on specific clinical guidelines.

Not Medically Necessary

Certain studies, treatments, procedures, or devices may be considered not medically necessary if there is supporting evidence but one of the following is present:

- Not clinically appropriate in terms of type, frequency, extent, site, and duration, and/or not considered effective for the individual's illness, injury or disease;
- Clinical utility of the technology, drug, device, treatment or procedure has not been demonstrated for a diagnosis, treatment, evaluation or prevention of the specific illness, condition or disease based on evidence-based clinical standards of care;
- More costly than an alternative service or sequence of services that are at least as likely to produce equivalent therapeutic or diagnostic results as to the diagnosis or treatment of a condition;
- Primarily for the convenience of the individual seeking medical services, health care provider, or other physicians or healthcare providers;
- Supporting evidence and/or collective opinion of support demonstrates that there is an alternative that is more appropriate/effective for diagnosis, treatment, or evaluation of a condition.

Supporting evidence includes standards that are based on credible scientific evidence published in peer-reviewed medical literature (such as well conducted randomized clinical trials or cohort studies with a sample size of sufficient statistical power) generally recognized by the relevant medical community. Collective opinion of support includes physician specialty society recommendations and the views of physicians practicing in relevant clinical areas when physician specialty society recommendations are not available. Determination of not medically necessary is based on specific clinical guidelines.

Special Considerations for Laboratory Testing

Laboratory-based testing is defined in terms of both the underlying technology used and, the indication for testing (i.e.: syndrome, condition, etc.). This is due to the ubiquitous use of specific technologies in laboratory medicine.

4. Per Compliance Internal policy: Clinical Certification of Services – Initial UM 0045:
   a. Experimental/Investigational: The use of a technology, drug, device, treatment, or procedure that has not been proven or recognized as having proven benefit in clinical medicine for any condition, illness, disease, or injury being treated.
   b. Medical Necessity: Refers to services or supplies for diagnosing, evaluating, treating or preventing an injury, illness, condition or disease, based on evidence-based clinical standards of care. Medically necessary services are accepted health care services and supplies provided by health care entities, appropriate to evaluation and treatment of a disease, condition, illness or injury and consistent with the applicable standard of care. Determination of medical necessity is based on specific clinical guidelines. (NCQA 2025 Standards; CMS; American College of Medical Quality)

Guideline Development (Preface-1.1)

PRF.GG.0001.1.A

v2.0.2026

- These evidence-based, proprietary clinical guidelines evaluate a range of advanced imaging and procedures, including NM, US, CT, MRI, PET, Radiation Oncology, Sleep Studies, Gastrointestinal Endoscopy, as well as Cardiac, Musculoskeletal, and Spine interventions.
- EviCore reserves the right to change and update the guidelines. The guidelines undergo a formal review annually. These clinical guidelines are based on current evidence supported by major national and international association and society guidelines and criteria, peer-reviewed literature, and major treatises, as well as input from health plans and practicing academic and community-based physicians.
- These guidelines are not intended to supersede or replace sound medical judgment, but instead, should facilitate the identification of the most appropriate imaging or other designated procedure given the individual's clinical condition. These guidelines are written to cover medical conditions as experienced by the majority of individuals. However, these guidelines may not be applicable in certain clinical circumstances, and physician judgment can override the guidelines.
- These guidelines provide evidence-based, clinical benefits with a focus on health care quality and patient safety.
- Clinical decisions, including treatment decisions, are the responsibility of the individual and his/her provider. Clinicians are expected to use independent medical judgment, which takes into account the clinical circumstances to determine individual management decisions.

Benefits, Coverage Policies, and Eligibility Issues (Preface-2.1)

PRF.BC.0002.1.U
v2.0.2026

Medicare Coverage Policies

- See EviCore's **Medicaid and Medicare Hierarchy and Application**.

Investigational and Experimental Studies

- See EviCore's **Guideline Definitions.**

Clinical and Research Trials

- Similar to investigational and experimental studies, clinical trial imaging requests are reviewed to determine whether they meet Health Plan coverage and these evidence-based clinical guidelines.
- Imaging studies which are inconsistent with established clinical standards, or are requested for data collection and not used in direct clinical management are not medically necessary.

CPT Codes

- The inclusion of any CPT code in the clinical guidelines does not imply that the code is under management or requires prior authorization.

Clinical Information (Preface-3.1)

PRF.CL.0003.1.A
v2.0.2026

Clinical Documentation and Age Considerations

- These clinical guidelines use an evidence-based approach to determine the most appropriate procedure for each individual, at the most appropriate time in the diagnostic and treatment cycle. These clinical guidelines are framed by:
  - clinical presentation of the individual, rather than the studies requested
  - adequate clinical information that must be submitted to EviCore in order to establish medical necessity for advanced imaging or other designated procedures including, but not limited to, the following:
    - Pertinent clinical evaluation since the onset or change in symptoms including a detailed history, physical examination, appropriate laboratory studies, and appropriate prior imaging studies.
      - Condition-specific guideline sections may describe additional clinical information which is required for a pertinent clinical evaluation.
      - The Spine and Musculoskeletal guidelines require x-ray studies from when the current episode of symptoms has started or changed.
      - Advanced imaging or other designated procedures should not be ordered prior to clinical evaluation of an individual by the physician treating the individual. This may include referral to a consultant specialist who will make further treatment decisions.
      - Other meaningful technological contact (telehealth visit, telephone or video call, electronic mail or messaging) since the onset or change in symptoms by an established individual can serve as a pertinent clinical evaluation.
        - Some conditions may require a face-to-face evaluation as discussed in the applicable condition-specific guideline sections.
    - A recent clinical evaluation may be unnecessary if the individual is undergoing a guideline-supported, scheduled follow-up imaging or other designated procedural evaluation. Exceptions due to routine surveillance indications are addressed in the applicable condition-specific guideline sections.
  - The evidence-based approach to determine the most appropriate procedure for each individual requires submission of medical records pertinent to the requested imaging or other designated procedures.
- Many conditions affecting the pediatric population are different diagnoses than those occurring in the adult population. For those diseases which occur in both pediatric and adult populations, minor differences may exist in management due to individual age, comorbidities, and differences in disease natural history between children and adults.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Individuals who are 18 years old or younger should be imaged according to the Pediatric Imaging Guidelines if discussed in the condition-specific guideline sections. Any conditions not specifically discussed in the Pediatric Imaging Guidelines should be imaged according to the General Imaging Guidelines. Individuals who are >18 years old should be imaged according to the General Imaging Guidelines, except where directed otherwise by a specific guideline section.

General Imaging Information

- "Standard" or "conventional" imaging is most often performed in the initial and subsequent evaluations of malignancy. Standard or conventional imaging includes plain film, CT, MRI, or US.
  - Often, further advanced imaging is needed when initial imaging, such as ultrasound, CT, or MRI does not answer the clinical question. Uncertain, indeterminate, inconclusive, or equivocal may describe these situations.
- Appropriate use of contrast is a very important component of evidence-based advanced imaging use.
  - The appropriate levels of contrast for an examination (i.e., without contrast, with contrast, without and with contrast) is determined by the evidence-based guidance reflected in the condition-specific guideline sections.
  - If, during the performance of a non-contrast imaging study, there is the unexpected need to use contrast in order to evaluate a possible abnormality, then that is appropriate.

Ultrasound

- Diagnostic ultrasound uses high-frequency sound waves to evaluate soft tissue structures and vascular structures utilizing grey scale and Doppler techniques.
- Ultrasound allows for dynamic real-time imaging at the bedside.
  - Ultrasound is limited in areas where there is dense bone or other calcification.
  - Ultrasound also has a relatively limited imaging window so may be of limited value in evaluating very large abnormalities.
  - In general, ultrasound is highly operator-dependent, and proper training and experience are required to perform consistent, high-quality evaluations.
- Indications for ultrasound may include, but are not limited to, the following:
  - Obstetric and gynecologic imaging
  - Soft tissue and visceral imaging of the chest, abdomen, pelvis, and extremities
  - Brain and spine imaging when not obscured by dense bony structures
  - Vascular imaging when not obscured by dense bony structures
  - Procedural guidance when not obscured by dense bony structures
  - Initial evaluation of ill-defined soft tissue masses or fullness and differentiating adenopathy from mass or cyst. Prior to advanced imaging, ultrasound can be

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

very beneficial in selecting the proper modality, body area, image sequences, and contrast level that will provide the most definitive information for the individual.
- More specific guidance for ultrasound usage, including exceptions to this general guidance, can be found throughout the condition-specific guidelines.

Computed Tomography (CT)

- The AMA CPT® manual does not describe nor assign any minimum or maximum number of sequences for any CT study. CT imaging protocols are often influenced by the individual's clinical situation and additional sequences are not uncommon. There are numerous CT protocols that may be performed to evaluate specific clinical questions, and this technology is constantly undergoing development.
- CT utilizes ionizing radiation to create cross-sectional and volumetric images of the body.
  - Advantages over ultrasound include a much larger field of view and faster completion time in general. Disadvantages compared to ultrasound include lack of portability and exposure to ionizing radiation.
  - Advantages over MRI include faster imaging and a more spacious scanner area limiting claustrophobia. Disadvantages compared to MRI include decreased soft tissue definition, especially with non-contrast imaging, and exposure to ionizing radiation.
- CT can be performed without, with, or without and with intravenous (IV) contrast depending on the clinical indication and body area.
  - In general, non-contrast imaging is appropriate for evaluating structures with significant tissue density differences such as lung parenchyma and bony structures, or when there is a contraindication to contrast.
  - In general, CT with contrast is the most common level of contrast and can be used when there is need for improved vascular or soft tissue resolution, including better characterization of known or suspected malignancy, as well as infectious and inflammatory conditions.
  - CT without and with contrast has a limited role as the risks of doubling the ionizing radiation exposure rarely outweigh the benefits of multiphasic imaging, though there are some exceptions which include, but are not limited to, the following:
    - Characterization of a mass
    - Characterization of arterial and venous anatomy
    - CT with contrast may be used to better characterize findings on a very recent (within two weeks) inconclusive non-contrast CT where the guidelines would support CT without and with contrast.
  - More specific guidance for CT contrast usage, including exceptions to this general guidance, can be found throughout the condition-specific guidelines.
- Shellfish allergy:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - It is commonly assumed that an allergy to shellfish indicates iodine allergy, and that this implies an allergy to iodinated contrast media used with CT. However, this is NOT true. Shellfish allergy is due to tropomyosins. Iodine plays no role in these allergic reactions. Allergies to shellfish do not increase the risk of reaction to iodinated contrast media any more than that of other allergens.
- Enteric contrast (oral or rectal) is sometimes used in abdominal imaging. There is no specific CPT® code which refers to enteric contrast.
- The appropriate contrast level and anatomic region in CT imaging is specific to the clinical indication as listed in the condition-specific guideline sections.
- CT should not be used to replace MRI in an attempt to avoid sedation unless it is listed as a recommended study in the appropriate condition-specific guideline.
- There are significant potential adverse effects associated with the use of iodinated contrast media. These include hypersensitivity reactions, thyroid dysfunction, and contrast-induced nephropathy (CIN). Individuals with impaired renal function are at increased risk for CIN.
- Both contrast CT and MRI are considered to have the same risk profile with renal failure (GFR <30mL/min).
- The use of CT contrast should proceed with caution in pregnant and breastfeeding individuals. There is a theoretical risk of contrast toxicity to the fetal and infant thyroid. The procedure can be performed if the specific need for that contrast-enhanced procedure outweighs risk to the fetus. Breastfeeding individuals may reduce this risk by choosing to pump and discard breast milk for 12-24 hours after the contrast injection.
- CT without contrast is medically necessary if clinical criteria for CT with contrast are met AND the individual has/is:
  - elevated blood urea nitrogen (BUN) and/or creatinine
  - renal insufficiency
  - allergies to iodinated contrast
  - thyroid disease which could be treated with I-131
  - diabetes
  - very elderly
  - urgent or emergent settings due to availability
  - trauma
- CT is superior to other imaging modalities in certain conditions including, but not limited to, the following:
  - Screening following trauma
  - Imaging pulmonary disease
  - Imaging abdominal and pelvic viscera
  - Imaging of complex fractures

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - Evaluation of inconclusive findings on Ultrasound or MRI, or if there is a contraindication to MRI
- More specific guidance for CT usage, including exceptions to this general guidance, can be found throughout the condition-specific guidelines.

Magnetic Resonance Imaging (MRI)

- The AMA CPT® manual does not describe nor assign any minimum or maximum number of sequences for any MRI study. MRI protocols are often influenced by the individual's clinical situation and additional sequences are not uncommon. There are numerous MRI sequences that may be performed to evaluate specific clinical questions, and this technology is constantly undergoing development.
- Magnetic Resonance Imaging (MRI) utilizes the interaction between the intrinsic radiofrequency of certain Molecules in the body (hydrogen in most cases) and a strong external magnetic field.
  - MRI is often superior for advanced imaging of soft tissues and can also define physiological processes in some instances (e.g., edema, loss of circulation [AVN], and increased vascularity [tumors]).
  - MRI does not use ionizing radiation, and even non-contrast images have much higher soft tissue definition than CT or Ultrasound.
  - MRI typically takes much longer than either CT or Ultrasound, and for some individuals may require sedation. It is also much more sensitive to individual motion that can degrade image quality than either CT or Ultrasound.
- MRI Breast and MRI Chest are not interchangeable, as they focus detailed sequences on different adjacent body parts.
- MRI may be utilized either as the primary advanced imaging modality, or when further definition is needed based on CT or ultrasound imaging.
- Most orthopedic and dental implants are not magnetic. These include hip and knee replacements; plates, screws, and rods used to treat fractures; and cavity fillings. Yet, all of these metal implants can distort the MRI image if near the part of the body being scanned.
  - Other implants, however, may have contraindications to MRI. These include the following:
    - pacemakers
    - ICD or heart valves
    - metal implants in the brain
    - metal implants in the eyes or ears
    - infusion catheters and bullets or shrapnel
  - CT can therefore be an alternative study to MRI in these scenarios.
- The contrast level and anatomic region in MRI imaging is specific to the clinical indication, as listed in the specific guideline sections.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- MRI utilizing Xenon Xe 129 (CPT® C9791) for contrast is considered investigational and experimental at this time. MRI with or with and without contrast in these guidelines refers to MRI utilizing gadolinium for contrast.
- MRI is commonly performed without, and without and with contrast.
  - Non-contrast imaging offers excellent tissue definition.
  - Imaging without and with contrast is commonly used when needed to better characterize tissue perfusion and vascularization.
    - Most contrast is gadolinium-based and causes T2 brightening of the vascular and extracellular spaces.
    - Some specialized gadolinium and non-gadolinium contrast agents are available and are most commonly used for characterizing liver lesions.
  - MRI with contrast only is rarely appropriate and is usually used to better characterize findings on a recent inconclusive non-contrast MRI, commonly called a completion study.
  - MRI contrast is relatively contraindicated in pregnant individuals.
  - More specific guidance for MRI contrast usage, including exceptions to this general guidance, can be found throughout the condition-specific guidelines.
- MRI may be preferred in individuals with renal failure and in individuals allergic to intravenous CT contrast.
  - Both contrast CT and MRI are considered to have the same risk profile with renal failure (GFR <30mL/min).
  - Gadolinium can cause Nephrogenic Systemic Fibrosis (NSF). The greater the exposure to gadolinium in individuals with a low GFR (especially if on dialysis), the greater the chance of individuals developing NSF.
  - Multiple studies have demonstrated potential for gadolinium deposition following the use of gadolinium-based contrast agents (GBCAs) for MRI studies. The U.S. Food and Drug Administration (FDA) has noted that there is currently no evidence to suggest that gadolinium retention in the brain is harmful and restricting GBCAs use is not warranted at this time. It has been recommended that GBCA use should be limited to circumstances in which additional information provided by the contrast agent is necessary and the necessity of repetitive MRIs with GBCAs should be assessed.
- A CT is medically necessary in place of an MRI when clinical criteria are met for MRI AND there is a contraindication to having an MRI (e.g., pacemaker, ICD, insulin pump, neurostimulator, etc.).
  - When replacing MRI with CT, contrast level matching should occur as follows:
    - MRI without contrast → CT without contrast
    - MRI without and with contrast → CT with contrast or CT without and with contrast
- The following situations may impact the appropriateness for MRI and/or MR contrast:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - Caution should be taken in the use of gadolinium in individuals with renal failure.
  - The use of gadolinium contrast agents is relatively contraindicated during pregnancy unless the specific need for that procedure outweighs risk to the fetus.
  - MRI can be performed for non-ferromagnetic body metals (i.e., titanium), although some imaging facilities will consider it contraindicated if recent surgery, regardless of the metal type.
- MRI should not be used as a replacement for CT for the sole reason of avoidance of ionizing radiation when MRI is not medically necessary in the condition-based guidelines, since it does not solve the problem of overutilization.
- MRI is superior to other imaging modalities in certain conditions including, but not limited to, the following:
  - Imaging the brain and spinal cord
  - Characterizing visceral and musculoskeletal soft tissue masses
  - Evaluating musculoskeletal soft tissues including ligaments and tendons
  - Evaluating inconclusive findings on ultrasound or CT
  - Individuals who are pregnant or have high radiation sensitivity
  - Suspicion, diagnosis, or surveillance of infections
- More specific guidance for MRI usage, including exceptions to this general guidance, can be found throughout the condition-specific guidelines.

Positron Emission Tomography (PET)

- PET is a nuclear medicine study that uses a positron emitting radiotracer to create cross-sectional and volumetric images based on tissue metabolism.
- Conventional imaging (frequently CT, sometimes MRI or bone scan) of the affected area(s) drives much of initial and restaging and surveillance imaging for malignancy and other chronic conditions. PET is not medically necessary for surveillance imaging unless specifically stated in the condition-specific guideline sections.
- PET/MRI is generally not medically necessary, see **PET-MRI (Preface-5.3)**.
- PET is rarely performed as a single modality, but is typically performed as a combined PET/CT.
  - The unbundling of PET/CT into separate PET and diagnostic CT CPT® codes is not medically necessary, because PET/CT is done as a single study.
- PET/CT lacks the tissue definition of CT or MRI but is fairly specific for metabolic activity based on the radiotracer used.
- Indications for PET/CT may include the following:
  - Oncologic Imaging for evaluation of tumor metabolic activity
  - Cardiac Imaging for evaluation of myocardial metabolic activity
  - Brain Imaging for evaluation of metabolic activity for procedural planning
- More specific guidance for PET usage, including exceptions to this general guidance, can be found throughout the condition-specific guidelines.

Overutilization of Advanced Imaging

- A number of reports describe overutilization in many areas of advanced imaging and other procedures, which may include the following:
  - High-level testing without consideration of less invasive, lower cost options which may adequately address the clinical question at hand
  - Excessive radiation and costs with unnecessary testing
  - Defensive medical practice
  - CT without and with contrast (so called “double contrast studies") requests, which have few current indications
  - MRI requested in place of CT to avoid radiation without considering the primary indication for imaging
  - Adult CT settings and protocols used for smaller people and children
  - Unnecessary imaging procedures when the same or similar studies have already been conducted
- A review of the imaging or other relevant procedural histories of all individuals presenting for studies has been recognized as one of the more important processes that can be significantly improved. By recognizing that a duplicate or questionably medically necessary imaging study has been ordered for individuals, it may be possible to avoid exposing them to unnecessary risks. To avoid these unnecessary risks, the precautions below should be considered:
  - The results of initial diagnostic tests or radiologic studies to narrow the differential diagnosis should be obtained prior to performing further tests or radiologic studies.
  - The clinical history should include a potential indication such as a known or suspected abnormality involving the body part for which the imaging study is being requested. These potential indications are addressed in greater detail within the applicable guidelines.
  - The results of the requested imaging procedures should be expected to have an impact on individual management or treatment decisions.
  - Repeat imaging studies are not generally necessary unless there is evidence of disease progression, recurrence of disease, and/or the repeat imaging will affect an individual’s clinical management.
- Pre-operative imaging/pre-surgical planning imaging/pre-procedure imaging is not medically necessary if the surgery/procedure is not medically necessary. Once the procedure has been approved or if the procedure does not require prior authorization, the appropriate pre-procedural imaging may be approved.

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants

Click Here to Return to the Main TOC

of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

3D Rendering (Preface-4.1)

PRF.CD.0004.1.U
v2.0.2026

CPT® 76376 and CPT® 76377:

- Both codes require concurrent supervision of the image post-processing 3D manipulation of the volumetric data set and image rendering.
  - Concurrent supervision is defined as active physician participation in and monitoring of the reconstruction process including design of the anatomic region that is to be reconstructed; determination of the tissue types and actual structures to be displayed (e.g., bone, organs, and vessels); determination of the images or cine loops that are to be archived; and monitoring and adjustment of the 3D work product. The American College of Radiology (ACR) recommends that it is best to document the physician's supervision or participation in the 3D reconstruction of images.
- These two codes differ in the need for and use of an independent workstation for post-processing.
  - CPT® 76376 reports procedures not requiring image post-processing on an independent workstation.
  - CPT® 76377 reports procedures that require image post-processing on an independent workstation.
- These 3D rendering codes should not be used for 2D reformatting.
- Two-dimensional reconstruction (e.g., reformatting an axial scan into the coronal plane) is now included in all cross-sectional imaging base codes and is not separately reimbursable.
- The codes used to report 3D rendering for ultrasound and echocardiography are also used to report the 3D post processing work on CT, MRI, and other tomographic modalities.
- Providers may be required to obtain prior authorization on these 3D codes even if prior authorization is not required for the echocardiography and/or ultrasound procedure codes. It may appear that EviCore pre-authorizes echocardiography and/or ultrasound when, in fact, it may only be the 3D code that needs the prior authorization.
- CPT® codes for 3D rendering should not be billed in conjunction with computer-aided detection (CAD), MRA, CTA, nuclear medicine SPECT studies, PET, PET/CT, stereotactic localization (CPT® 77011 or CPT® 70486 if used), Mammogram, MRI Breast, US Breast, CT Colonography (virtual colonoscopy), Cardiac MRI, Cardiac CT, or Coronary CTA studies.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- CPT® 76377 (3D rendering requiring image post-processing on an independent workstation) or CPT® 76376 (3D rendering not requiring image post-processing on an independent workstation) can be considered in the following clinical scenarios:
  - Bony conditions:
    - Evaluation of congenital skull abnormalities in newborns, infants, and toddlers (usually for pre-operative planning)
    - Complex fractures (comminuted or displaced)/dislocations of any joint (for pre-operative planning when conventional imaging is insufficient)
    - Spine fractures, pelvic/acetabulum fractures, intra-articular fractures (for pre-operative planning when conventional imaging is insufficient)
    - Pre-operative planning for other complex surgical cases
    - Complex facial fractures
  - Pre-operative planning for other complex surgical cases
  - Cerebral angiography
  - Pelvis conditions:
    - Uterine intra-cavitary lesion when initial US is equivocal: See **Abnormal Uterine Bleeding (AUB) (PV-2.1)** and **Leiomyoma/Uterine Fibroids (PV-12.1)** in the Pelvis Imaging Guidelines.
    - Hydrosalpinxes or peritoneal cysts when initial US is indeterminate: See **Complex Adnexal Masses (PV-5.3)** in the Pelvis Imaging Guidelines.
    - Lost IUD (inability to feel or see IUD string) with initial US: See **Intrauterine Device (PV-10.1)** in the Pelvis Imaging Guidelines.
    - Uterine anomalies with initial US: See **Uterine Anomalies (PV-14.1)** in the Pelvis Imaging Guidelines.
    - Infertility: See **Initial Infertility Evaluation, Female (PV-9.1)** in the Pelvis Imaging Guidelines.
  - Abdomen conditions:
    - CT Urogram: See **Hematuria and Hydronephrosis (AB-39)** in the Abdomen Imaging Guidelines.
    - MRCP: See **MR Cholangiopancreatography (MRCP) (AB-27)** in the Abdomen Imaging Guidelines.

CT-, MR-, or Ultrasound-Guided Procedures (Preface-4.2)

PRF.CD.0004.2.A
v2.0.2026

- CT-, MR-, and Ultrasound-guidance procedure codes contain all of the imaging necessary to guide a needle or catheter. It is inappropriate to routinely bill a diagnostic procedure code in conjunction with a guidance procedure code.
- Imaging studies performed as part of a CT-, MR-, or Ultrasound-guided procedure should be reported using the CPT® codes in the following table:

TABLE: Imaging Guidance Procedure Codes

CPT®	Description
19085	Biopsy, breast, with placement of breast localization device(s), when performed, and imaging of the biopsy specimen, when performed, percutaneous; first lesion, including MR guidance
19086	Biopsy, breast, with placement of breast localization device(s), when performed, and imaging of the biopsy specimen, when performed, percutaneous; each additional lesion, including MR guidance
75989	Imaging guidance for percutaneous drainage with placement of catheter (all modalities)
76942	Ultrasonic guidance for needle placement
77011	CT guidance for stereotactic localization
77012	CT guidance for needle placement
77013	CT guidance for, and monitoring of parenchymal tissue ablation
77021	MR guidance for needle placement
77022	MR guidance for, and monitoring of parenchymal tissue ablation
C8001	3D anatomical segmentation imaging for preoperative planning, data preparation and transmission, obtained from previous diagnostic CT or MR examination of the same anatomy

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

CPT® 19085 and CPT® 19086

- The proper way to bill an MRI-guided breast biopsy is CPT® 19085 (Biopsy, breast, with placement of breast localization device(s), when performed, and imaging of the biopsy specimen, when performed, percutaneous; first lesion, including MR guidance). Additional lesions should be billed using CPT® 19086.
  - **CPT® 77021** (MR guidance for needle placement) is not an appropriate code for a breast biopsy.

CPT® 75989

- This code is used to report imaging guidance for a percutaneous drainage procedure in which a catheter is left in place.
- This code can be used to report whether the drainage catheter is placed under fluoroscopy, Ultrasound-, CT-, or MR-guidance modality.

CPT® 77011

- A stereotactic CT localization scan is frequently obtained prior to sinus surgery. The dataset is then loaded into the navigational workstation in the operating room for use during the surgical procedure. The information provides exact positioning of surgical instruments with regard to the individual's 3D CT images.
- In most cases, the pre-operative CT is a technical-only service that does not require interpretation by a radiologist.
  - The imaging facility should report CPT® 77011 when performing a scan not requiring interpretation by a radiologist.
  - If a diagnostic scan is performed and interpreted by a radiologist, the appropriate diagnostic CT code (e.g., CPT® 70486) should be used.
  - It is not appropriate to report both CPT® 70486 and CPT® 77011 for the same CT stereotactic localization imaging session.
  - 3D Rendering (CPT® 76376 or CPT® 76377) should not be reported in conjunction with CPT® 77011 (or CPT® 70486 if used). The procedure inherently generates a 3D dataset.

CPT® 77012 (CT) and CPT® 77021 (MR)

- These codes are used to report imaging guidance for needle placement during biopsy, aspiration, and other percutaneous procedures.
- They represent the radiological supervision and interpretation of the procedure and are often billed in conjunction with surgical procedure codes.
  - For example, CPT® 77012 is reported when CT guidance is used to place the needle for a conventional arthrogram.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Only codes representing percutaneous surgical procedures should be billed with CPT® 77012 and CPT® 77021. It is inappropriate to use with surgical codes for open, excisional, or incisional procedures.
- **CPT® 77021** (MR guidance for needle placement) is not an appropriate code for breast or prostate biopsy.
  - CPT® 19085 would be appropriate for the first breast biopsy site and CPT® 19086 would be appropriate for additional concurrent biopsies.

CPT® 77013 (CT) and CPT® 77022 (MR)

- These codes include the initial guidance to direct a needle electrode to the tumor(s), monitoring for needle electrode repositioning within the lesion, and as necessary for multiple ablations to coagulate the lesion and confirmation of satisfactory coagulative necrosis of the lesion(s) and comparison to pre-ablation images.
  - **NOTE:** CPT® 77013 should only be used for non-bone ablation procedures.
    - CPT® 20982 includes CT guidance for bone tumor ablations.
  - Only codes representing percutaneous surgical procedures should be billed with CPT® 77013 and CPT® 77022. It is inappropriate to use with surgical codes for open, excisional, or incisional procedures.
- CPT® 77012 and CPT® 77021 (as well as guidance codes CPT® 76942 [US], and CPT® 77002 - CPT® 77003 [fluoroscopy]) describe radiologic guidance by different modalities.
  - Only one unit of any of these codes should be reported per individual encounter (date of service). The unit of service is considered to be the individual encounter, not the number of lesions, aspirations, biopsies, injections, or localizations.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Unlisted Procedures/Therapy Treatment Planning (Preface-4.3)

PRF.CD.0004.3.U
v2.0.2026

Unlisted Procedures

CPT®	Description
78999	Unlisted procedure, diagnostic nuclear medicine
76498	Unlisted MR procedure (e.g., diagnostic or interventional)
76497	Unlisted CT procedure (e.g., diagnostic or interventional)

- For general information related to unlisted procedures, please refer to **Management of Unlisted Codes**.
- These unlisted codes should be reported whenever a diagnostic or interventional CT or MR study is performed in which an appropriate anatomic site-specific code is not available.
  - A Category III code that describes the procedure performed must be reported rather than an unlisted code if one is available.
- CPT® 76497 or CPT® 76498 (Unlisted CT or MRI procedure) is medically necessary in the following clinical scenarios:
  - Studies done for navigation and planning for neurosurgical procedures (i.e. Stealth or Brain Lab Imaging)
  - Custom joint arthroplasty planning (not as an alternative recommendation): See **Osteoarthritis (MS-12.1)** in the Musculoskeletal Imaging Guidelines.
  - Any procedure/surgical planning if thinner cuts or different positional acquisition (than those on the completed diagnostic study) are needed. These could include navigational bronchoscopy. See **Navigational Bronchoscopy (CH-1.7)** in the Chest Imaging Guidelines.

Therapy Treatment Planning

- Radiation Therapy Treatment Planning: See **Unlisted Procedure Codes in Oncology (ONC-1.5)** in the Oncology Imaging Guidelines.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Unilateral Versus Bilateral Breast MRI (Preface-4.4)

PRF.CD.0004.4.A

v2.0.2026

- Diagnostic MRI of both breasts should be coded as CPT® 77049 regardless of whether both breasts are imaged simultaneously or whether unilateral breast MRI is performed in two separate imaging sessions.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

CPT® 76380 Limited or Follow-up CT (Preface-4.5)

PRF.CD.0004.5.A

v2.0.2026

- CPT® 76380 describes a limited or follow-up CT scan. The code is used to report any CT scan, for any given area of the body, in which the work of a full diagnostic code is not performed.
- Common examples include, but are not limited to, the following:
  - Limited sinus CT imaging protocol
  - Limited or follow-up slices through a known pulmonary nodule
  - Limited slices to assess a non-healing fracture (such as the clavicle)
- Limited CT (CPT® 76380) is not medically necessary for treatment planning purposes. See **Unlisted Procedure Codes in Oncology (ONC-1.5)** in the Oncology Imaging Guidelines.
- It is inappropriate to report CPT® 76380, in conjunction with other diagnostic CT codes, to cover 'extra slices' in certain imaging protocols.
  - There is no specific number of sequences or slices defined in any CT CPT® code definition.
  - The AMA, in *CPT® 2019*, does not describe nor assign any minimum or maximum number of sequences or slices for any CT study.
    - A few additional slices or sequences are not uncommon.
    - CT imaging protocols are often influenced by the individual's clinical situation. Sometimes the protocols require more time and sometimes less.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

SPECT/CT Imaging (Preface-4.6)

PRF.CD.0004.6.A

v2.0.2026

- SPECT/CT involves SPECT (Single Photon Emission Computed Tomography) nuclear medicine imaging and CT for optimizing location, accuracy, and attenuation correction and combines functional and anatomic information.
  - Common studies using this modality include ^{123}I- or ^{131}I-Metaiodobenzylguanidine (MIBG) and octreotide scintigraphy for neuroendocrine tumors.
- Hybrid Nuclear/CT scan can be reported as CPT® 78830 (single area and single day), CPT® 78831 (2 or more days), or CPT® 78832 (2 areas with one day and 2-day study).
- CPT® 78072 became effective January 1, 2013 for SPECT/CT parathyroid nuclear imaging.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

CPT® 76140 Interpretation of an Outside Study (Preface-4.7)

PRF.CD.0004.7.U

v2.0.2026

- It is inappropriate to use diagnostic imaging codes for interpretation of a previously performed exam that was completed at another facility.
  - If the outside exam is being used for comparison with a current exam, the diagnostic code for the current examination includes comparison to the prior study.
  - CPT® 76140 is the appropriate code to use for an exam which was completed elsewhere and a secondary interpretation of the images is requested.

Quantitative MR Analysis (Preface-4.8)

PRF.CD.0004.8.A

v2.0.2026

- Category III CPT® codes for quantitative analysis of multiparametric-MR (mp-MRI) data with and without an associated diagnostic MRI have been established. Quantitative mp-MRI uses software to analyze tissue physiology of visceral organs and other anatomic structures non-invasively.
- For criteria associated with these types of studies, please see the condition-specific guidelines.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

HCPCS Codes (Preface-4.9)

PRF.CD.0004.9.A

v2.0.2026

- Healthcare Common Procedure Coding System (HCPCS) codes are utilized by some hospitals in favor of the typical Level-III CPT® codes. These codes are typically 4 digits preceded by a C or S.
  - Many of these codes have similar code descriptions to Level-III CPT® codes (i.e., C8931 – MRA with dye, Spinal Canal; and, CPT® 72159 – MRA Spinal Canal).
  - If cases are submitted with HCPCS codes with similar code descriptions to the typical Level-III CPT® codes, those procedures should be managed in the same manner as the typical CPT® codes.
  - HCPCS code management is discussed further in the applicable guideline sections.
- Requests for many Healthcare Common Procedure Coding System (HCPCS) codes, including non-specific codes such as S8042 (Magnetic resonance imaging [MRI], low-field), should be redirected to a more appropriate and specific CPT® code. Exceptions are noted in the applicable guideline sections.

Whole Body CT Imaging (Preface-5.1)

PRF.WB.0005.1.U

v2.0.2026

- Whole-body CT or LifeScan (CT Brain, Chest, Abdomen, and Pelvis) for screening of asymptomatic individuals is not a covered benefit. The performance of whole-body screening CT examinations in healthy individuals does not meet any of the current validity criteria for screening studies and there is no clear documentation of benefit versus radiation risk.
- Whole-body low-dose skeletal CT is supported for oncologic staging in Multiple Myeloma. See **Multiple Myeloma and Plasmacytomas (ONC-25)** in the Oncology Imaging Guidelines.

Proprietary Information of UnitedHealthcare.

Whole-Body MR Imaging (Preface-5.2)

PRF.WB.0005.2.A

v2.0.2026

- Whole-body MRI (WBMRI) is, with the exception of select cancer predisposition syndromes and autoimmune conditions discussed below, generally not medically necessary at this time due to lack of standardization in imaging technique and lack of evidence that WBMRI improves outcome for any individual disease state.
  - While WBMRI has the benefit of whole-body imaging and lack of radiation exposure, substantial variation still exists in the number of images, type of sequences (STIR vs. diffusion weighting, for example), and contrast agent(s) used.
- Coding considerations:
  - There are no established CPT® or HCPCS codes for reporting WBMRI.
  - WBMRI is at present only reportable using CPT® 76498. All other methods of reporting whole-body MRI are inappropriate including the following:
    - Separate diagnostic MRI codes for multiple individual body parts
    - MRI Bone Marrow Supply (CPT® 77084)
- Disease-specific considerations:
  - Cancer screening:
    - Interval WBMRI is recommended for cancer screening in individuals with select cancer predisposition syndromes. Otherwise, WBMRI has not been shown to improve outcomes for cancer screening.
      - For additional information, see **Li-Fraumeni Syndrome (LFS) (PEDONC-2.2)**, **Neurofibromatosis 1 and 2 (NF1 and NF2) (PEDONC-2.3)**, **Rhabdoid Tumor Predisposition Syndrome (PEDONC-2.11)**, **Hereditary Paraganglioma-Pheochromocytoma (HPP) Syndromes (PEDONC-2.13)**, **Constitutional Mismatch Repair Deficiency (CMMRD or Turcot Syndrome) (PEDONC-2.15)**, **Infantile Myofibromatosis (PEDONC-2.18)**, or **Bloom Syndrome (PEDONC-2.19)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
  - Cancer staging and restaging:
    - Whole-body MRI has limited indications in staging and restaging of multiple myeloma. See **Multiple Myeloma and Plasmacytomas (ONC-25)** in the Oncology Imaging Guidelines for additional details.
    - Evidence has not been published establishing WBMRI as a standard evaluation for any other type of cancer.
  - Autoimmune disease:
    - WBMRI can be approved in some situations for individuals with chronic recurrent multifocal osteomyelitis.

PET/MRI (Preface-5.3)

PRF.WB.0005.3.A

v2.0.2026

- PET/MRI is generally not medically necessary for a vast majority of oncologic and neurologic conditions due to lack of standardization in imaging technique and interpretation. However, it is medically necessary in select circumstances when the following criteria are met:
  - The individual meets condition-specific guidelines for PET/MRI OR
  - The individual meets ALL of the following:
    - The individual meets guideline criteria for PET/CT, **AND**
    - PET/CT is not available at the treating institution, **AND**
    - The provider requests PET/MRI in lieu of PET/CT
- When the above criteria are met, PET/MRI is reported using the code combination of PET Whole-Body (CPT® 78813) and MRI Unlisted (CPT® 76498). All other methods of reporting PET/MRI are inappropriate.
  - When clinically appropriate, diagnostic MRI codes can be medically necessary at the same time as the PET/MRI code combination.
- For more information, please see the appropriate condition-based guideline.

General Guidelines (AB-1.0)

AB.GG.0001.0.A

v1.0.2026

- A pertinent clinical evaluation since the new onset or change in symptoms is required prior to advanced imaging:
  - A pertinent clinical evaluation should include the following:
    - A detailed history and physical examination relevant to the current complaint
    - Appropriate laboratory studies
    - Non-advanced imaging modalities such as plain x-ray or ultrasound of the area of concern
  - For an established individual, a meaningful technological contact (telehealth visit, telephone call, electronic mail, or messaging) since the onset of change in symptoms can serve as a pertinent clinical evaluation.

Red Flag Findings

- The following signs and symptoms can be indicative of more serious conditions. Documentation of abdominal pain along with ANY of the following warrants exclusion from prerequisites to advanced imaging:
  - History of malignancy with a likelihood or propensity to metastasize to abdomen
  - Immunocompromised individual (e.g., on immunosuppressive therapy, history of HIV)
  - Fever (≥101 degrees Fahrenheit)
  - Elevated WBC >10,000, or above the upper limit of normal for the particular lab reporting the result
  - Low WBC (absolute neutrophil count <1000)
  - Palpable mass of clinical concern and/or without benign features
  - GI bleeding, overt or occult, not obviously hemorrhoidal
  - Abdominal tenderness documented as moderate or severe
  - Peritoneal signs, such as guarding or rebound tenderness
  - Suspected complication of bariatric surgery
  - Notation by the ordering provider that the individual has a "surgical abdomen"
  - Age ≥60 years with unintentional weight loss of ≥10 lbs. or ≥5% of body weight over 6 months or less, without an identifiable reason
- See the condition-specific sections for when the above list of exclusionary criteria apply and lead directly to advanced imaging.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Imaging Recommended Per Drug Manufacturer

- When follow-up imaging for the purposes of monitoring or screening is recommended in the package insert for a particular drug therapy or medication, that imaging may be medically necessary.

Complications Related to COVID-19

- Please refer to the appropriate condition-specific guideline relevant to the presenting signs or symptoms in individuals with potential sequelae of COVID-19.
  - Examples include:
    - For suspected acute mesenteric ischemia, see: **Mesenteric Ischemia (AB-6.1)**
    - For suspected renal failure, see: **Renal Failure (AB-36.1)**

Pre-operative Radiologic Imaging

- If imaging is requested by the operating surgeon to support planned surgery, the imaging is considered medically necessary.
- Please refer to the appropriate condition-specific guideline relevant to the clinical condition for pre-operative imaging indications (e.g., **Percutaneous Gastrostomy (AB-9.2)**)
- Radiologic therapeutic intervention is addressed elsewhere in this Guideline.
  - Radiologic management of lower GI bleeding, see: **Small Bowel Bleeding Suspected (AB-22.2)**
  - Radiologic management of mesenteric ischemia, see: **Mesenteric/Colonic Ischemia (AB-6.1)**
  - Radiologic management of portal hypertension, see: **Portal Hypertension (AB-26.3)**

3D Rendering

- CPT® 76377 (3D rendering requiring image post-processing on an independent workstation) or CPT® 76376 (3D rendering not requiring image post-processing on an independent workstation) is medically necessary in the following clinical scenarios:
  - Pre-operative planning for complex surgical cases
  - CT Urogram (See: **Hematuria and Hydronephrosis (AB-39)**)
  - MRCP (See: **MR Cholangiopancreatography (MRCP) (AB-27)**)
- CPT® codes for 3D rendering should not be billed in conjunction with computer-aided detection (CAD), MRA, CTA, nuclear medicine SPECT studies, PET, PET/CT, or CT Colonography (virtual colonoscopy).

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

Evidence Discussion

Except as noted in condition-specific sections of these Abdominal Guidelines, initial evaluation by ultrasound is generally prerequisite to advanced imaging modalities. Ultrasound requires no ionizing radiation, is cost effective, helps determine most appropriate next advanced imaging study (CT vs. MRI) and contrast level, is readily accessible, and often can be scheduled same day.

When Red Flag signs and symptoms are present, literature supports early use of computer tomography (CT) and/or magnetic resonance imaging (MRI) without need for a prior ultrasound. Red Flags include:

- Risk of metastases: Liver, lung, and regional lymph nodes are frequent metastatic targets readily identified by advanced abdominal imaging. Metastatic foci are less readily identified by ultrasound in the hollow viscus than solid abdominal organs - e.g., in high prevalence metastatic spread to the gas-filled stomach by breast cancer (27%), lung cancer (23%), renal cell cancer (7.6%), and malignant melanoma (7%).[20]
- Fever: Accompanied by abdominal pain, or in combination with vomiting, bloody stools, unexplained weight loss, or persistent fever requires urgent imaging evaluation. CT and MRI are better suited than ultrasound in localizing and characterizing gut-related urgencies such as bowel blockage, abdominal ischemia, acute inflammatory conditions (diverticulitis, flares of inflammatory bowel disease, perforation), and obstructing tumors.[21]
- Abnormal white cell number: Neutropenia or leukocytosis warrants definitive advanced imaging to avoid delays in diagnosis and treatment, especially in immunocompromised settings, for life-threatening pathology such as neutropenic enterocolitis (typhilitis) or the various infectious, inflammatory, or injurious conditions described in the Abdominal Guideline sections in which an elevated white cell count is seen.[22]
- Concerning palpable mass: The imaging approach to diagnosis varies by location and clinician-concern. For intra-abdominal masses, contrast-enhanced CT and ultrasound examination have demonstrated accuracy. For abdominal wall masses, which may arise from muscle, subcutaneous tissue, or connective tissue, MRI, CT, and ultrasound all provide diagnostic value. When mass is accompanied by abdominal pain, advanced imaging modalities may facilitate care.[23]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- GI bleeding: When the source of bleeding is unidentified after upper endoscopy and/or colonoscopy, subsequent diagnostic modalities should be guided by clinical presentation, hemodynamic stability, and local expertise. CT angiography demonstrates a sensitivity of 86% and specificity of 95% in acute GI bleeding and is useful in directing definitive hemostatic treatment.[24]
- Significant abdominal tenderness, with or without peritoneal signs: Rapid onset of severe abdominal pain with significant tenderness, an acute abdomen or surgical abdomen, may indicate a potentially life-threatening condition requiring urgent surgical intervention for which accurate and timely diagnosis is critical. Advanced imaging also offers greater accuracy than ultrasound in the setting of a painless acute abdomen seen in older people, children, the immunocompromised, and in the last trimester of pregnancy.[25]
- Suspected complication of bariatric surgery: Early advanced imaging followed by emergent intervention avoids morbidity in Roux-en-Y individuals with internal hernias or in balloon recipients with bowel obstruction or perforated gastrojejunal ulcer.[26]
- Unexplained weight loss: Problematic weight loss in the older adult is defined by the United States Omnibus Budget Reconciliation Act of 1987 (Title IV: subtitle C: Nursing Home Reform) as a loss of 5% of body weight in one month or 10% over a period of six months or longer. Unintentional weight loss is associated with an increased risk of death among older adults.[27]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Overview (AB-1.1)

AB.GG.0001.1.A

v1.0.2026

- GI Specialist evaluations can be helpful, particularly in determining mesenteric/colonic ischemia, diarrhea/constipation, irritable bowel syndrome (IBS), or need for MRCP.
- Abdominal imaging begins at the diaphragm and extends to the umbilicus or iliac crest.
- Pelvic imaging begins at the iliac crest and extends to the pubis.
  - The uterus, fallopian tubes and ovaries arise out of the pelvis and are considered pelvic organs. If the uterus or adnexa rise out of the pelvic cavity, above the level of the iliac crest or umbilicus on physical exam or previous imaging, abdominal imaging may be added for the completion of imaging.
- Imaging for clinical concerns at the dividing line can be providers' choice (abdomen and pelvis; abdomen or pelvis).

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

CT Imaging (AB-1.2)

AB.GG.0001.2.A

v1.0.2026

- CT imaging is a more generalized modality. CT Abdomen is usually performed with contrast (CPT® 74160):
  - Oral contrast has no relation to the IV contrast administered. Coding for contrast only refers to IV contrast. There is no coding for oral contrast.
  - Exceptions are noted in these guidelines and include:
    - CT Abdomen with contrast (CPT® 74160) or without and with contrast (CPT® 74170) with suspicion of a solid organ lesion (liver, kidney, pancreas, spleen)
      - Please refer to the specific guideline for the lesion in question for specific guidance.
    - CT Abdomen without contrast (CPT® 74150) or CT Abdomen and Pelvis without contrast (CPT® 74176) if there is renal insufficiency/failure, or a documented allergy to contrast. It can also be considered medically necessary for diabetics or the very elderly.
    - CT Abdomen and Pelvis without and with contrast (CPT® 74178 – CT Urogram) for certain urologic conditions (e.g. hematuria).
  - Shellfish allergy:
    - It is commonly assumed that an allergy to shellfish infers iodine allergy, and that this implies an allergy to CT iodinated contrast media. However, this is NOT true. Shellfish allergy is due to tropomysins. Iodine plays no role in these allergic reactions. Allergies to shellfish do not increase the risk of reaction to IV contrast any more than that of other allergens.
  - CT Abdomen and Pelvis, usually with contrast (CPT® 74177), is considered medically necessary when signs or symptoms are generalized, or involve a lower quadrant of the abdomen.
  - CT Enterography (CPT® 74177) combines CT imaging with large volumes of ingested neutral bowel contrast material to allow visualization of the small bowel.
  - CT Enteroclysis
    - A tube is placed through the nose or mouth and advanced into the duodenum or jejunum. Bowel contrast material is infused through the tube and CT imaging is performed either with or without intravenous contrast.
    - CT Enteroclysis is used to allow visualization of the small bowel wall and lumen. CT Enteroclysis may allow better or more consistent distention of the small bowel than CT Enterography.
    - Report by assigning: CPT® 74176 or CPT® 74177
  - Triple-phase CT
    - 3 phases of a triple-phase CT are:

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

    - 1) Hepatic arterial phase,
    - 2) Portal venous phase, and
    - 3) Washout or delayed acquisitions phase.
  - It should be noted that, in general, a pre-contrast or non-contrast CT is usually not needed in a standard triple-phase CT, except in those individuals previously treated with locoregional embolic or ablative therapies. Other specific instances in which a prior non-contrast CT is medically necessary for the evaluation of liver lesions are noted in **Liver Lesion Characterization (AB-29.1)**.
- CT Colonography (CTC)
  - There are 3 CPT® codes for CTC:
    - CPT® 74263: Screening CTC (only used for screening procedures)
    - CPT® 74261: CTC without contrast
    - CPT® 74262: CTC with contrast
  - See: **CT Colonography (CTC) (AB-25)** for further indications for these procedures

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

MR Imaging (AB-1.3)

AB.GG.0001.3.A

v1.0.2026

- MRI may be preferred as a more targeted study in cases of renal failure, in individuals allergic to intravenous CT contrast, and as noted in these guidelines.
  - MRI Abdomen with contrast only is essentially never performed. If contrast is indicated, MRI Abdomen without and with contrast (CPT® 74183) should be considered medically necessary.
  - For pregnant individuals ultrasound or MRI without contrast should be used to avoid radiation exposure. The use of gadolinium contrast agents is limited during pregnancy, as gadolinium contrast agents cross the placenta and enter the amniotic fluid with unknown long-term effects on the fetus.
    - See: **Pregnancy Considerations for Imaging (AB-1.12)** for additional discussion of this issue
- MR Elastography (CPT® 76391) replaces MRI Abdomen (CPT® 74183 or CPT® 74181) for requests for MR Elastography liver (See: **Liver Elastography (AB-45)**)

Proprietary Information of UnitedHealthcare.

MR Enterography and Enteroclysis Coding Notes (AB-1.4)

AB.GG.0001.4.A
v1.0.2026

- MR Enterography or Enteroclysis is reported in one of two ways:
  - MRI Abdomen without and with contrast (CPT® 74183), or
  - MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis with and without contrast (CPT® 72197)

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Ultrasound (AB-1.5)

AB.GG.0001.5.A

v1.0.2026

- Ultrasound, also called sonography, uses high frequency sounds waves to image body structures.
  - The routine use of 3D and 4D rendering (post-processing) in conjunction with ultrasound is not medically necessary.
  - All ultrasound studies require permanently recorded images either stored on film or in a Picture Archiving and Communication System (PACS).
  - The use of a hand-held or any Doppler device that does not create a hard-copy output is considered part of the physical examination and is not separately billable. This exclusion includes devices that produce a record that does not permit analysis of bi-directional vascular flow.
- Duplex scan describes an ultrasonic scanning procedure for characterizing the pattern and direction of blood flow in arteries and veins with the production of real-time images integrating B-mode 2D vascular structures, Doppler spectral analysis, and color flow Doppler imaging.
  - The minimal use of color Doppler alone, when performed for anatomical structure identification during a standard ultrasound procedure, is not separately reimbursable.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Abdominal Ultrasound (AB-1.6)

AB.GG.0001.6.A

v1.0.2026

- Complete abdominal ultrasound (CPT® 76700) includes all of the following required elements:
  - Liver, gallbladder, common bile duct, pancreas, spleen, kidneys, upper abdominal aorta, and inferior vena cava
  - If a particular structure or organ cannot be visualized, the report should document the reason.
- Limited abdominal ultrasound (CPT® 76705) is without all of these required elements and can refer to a specific study of a single organ, a limited area of the abdomen, or a follow-up study.
  - Further, CPT® 76705 should:
    - Be assigned to report follow-up studies once a complete abdominal ultrasound (CPT® 76700) has been performed; and
    - Be assigned to report ultrasonic evaluation of diaphragmatic motion; and
    - Be reported only once per individual imaging session; and
      - Not be reported with CPT® 76700 for the same individual for the same imaging session

Retroperitoneal Ultrasound (AB-1.7)

AB.GG.0001.7.A

v1.0.2026

- Complete retroperitoneal ultrasound (CPT® 76770) includes all of the following required elements:
  - Kidneys, lymph nodes, abdominal aorta, common iliac artery origins, inferior vena cava
  - For urinary tract indications, a complete study can consist of kidneys and bladder
- Limited retroperitoneal ultrasound (CPT® 76775) studies are without all of these required elements and can refer to a specific study of a single organ, a limited area of the abdomen, or a follow-up study.
  - Further, CPT® 76775 should:
    - Be assigned to report follow-up studies once a complete retroperitoneal ultrasound (CPT® 76770) has been performed; and
    - Be reported only once per individual imaging session; and
      - Not be reported with CPT® 76770 for the same individual for the same imaging session

Contrast-Enhanced Ultrasound (AB-1.9)

AB.GG.0001.9.A

v1.0.2026

Ultrasound with contrast (CEUS, CPT® 76978, CPT® 76979) is an emerging technology that may be as good, if not better, than CT or MRI in certain circumstances. Abdominal Imaging Guidelines address its use as appropriate. CPT® 76978 refers to the initial imaging of the first lesion, and CPT® 76979 refers to additional lesions that are imaged subsequently.

RADCAT Grading System (AB-1.11)

AB.GG.0001.11.A

v1.0.2026

- The RADCAT (Radiology Report Categorization) Grading System was developed in order to communicate to ordering physicians (most commonly in the ER setting) the relative urgency of a radiologic finding. It is not related to the LI-RADs reporting system, nor does it necessarily imply the need for follow-up imaging, as opposed to clinical follow-up. The rating system is as follows:
  - RADCAT 1: Normal Result
  - RADCAT 2: Routine Result
  - RADCAT 3: Result with recommendation for non-urgent routine follow-up
  - RADCAT 4: Priority Result
  - RADCAT 5: Critical Result

Pregnancy Considerations for Imaging (AB-1.12)

AB.GG.0001.12.A
v1.0.2026

The American College of Obstetricians and Gynecologists has issued guidelines with regards to imaging during pregnancy and lactation. Their recommendations are as follows:[15]

- Ultrasonography and magnetic resonance imaging (MRI), which are not associated with exposure to ionizing radiation, are the imaging modalities of choice for pregnant individuals. These modalities should be limited to situations in which the results are expected to address a clinically relevant question or otherwise provide medical benefit to the individual.
- With few exceptions, radiation exposure through radiography, computed tomography (CT) scan, or nuclear medicine imaging techniques is at a dose much lower than the exposure associated with fetal harm.
  - If these techniques are necessary in addition to ultrasound or MRI or are more readily available for the diagnosis in question, they should not be withheld from a pregnant individual.
- The use of gadolinium contrast with MRI should be limited; it may be used as a contrast agent in a pregnant individual only if it significantly improves diagnostic performance and is expected to improve fetal or maternal outcome.
- With regards to iodinated IV contrast media, “it is generally recommended that contrast only be used if absolutely required to obtain additional diagnostic information that will affect the care of the fetus or woman during pregnancy.”

Abdominal Pain (AB-2.2)

AB.AP.0002.2.A
v1.0.2026

- The presence of any red flag findings per **General Guidelines (AB-1.0)** precludes adjudication based on any other criteria.
- For pregnant individuals, see **Pregnancy Considerations for Imaging (AB-1.12)**
  - Abdominal and/or Pelvic and/or Transvaginal ultrasound (CPT® 76700 and/or CPT® 76856 and/or CPT® 76830) is medically necessary initially to avoid ionizing radiation.
  - MRI Abdomen and/or MRI Pelvis without contrast (CPT® 74181 and or CPT® 72195) is medically necessary if the initial US is considered non-diagnostic.
- For the evaluation of left lower (including suspected diverticulitis), right lower (including suspected appendicitis), left upper, mid-abdominal, and/or non-specific abdominal pain regardless of duration (acute or chronic, defined respectively as less than or to equal to 6 months, or greater than or equal to 6 months):
  - CT Abdomen with contrast (CPT® 74160) or CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary if ANY of the following are present:
    - Age ≥65
    - Prior Abdominal and/or Pelvic US appropriate to the area of concern have been performed and demonstrate a need for additional imaging OR do not explain the source of pain
    - Recent laboratory studies related to the current episode have been performed and are non-diagnostic OR do not point to a specific etiology
      - Laboratory studies may include: CBC with differential, CMP, BMP, chemistry profile including electrolytes, glucose, creatinine, BUN with liver chemistries, ESR, amylase and lipase, CRP, inflammatory markers, pregnancy testing for reproductive age individuals, and urinalysis
        - All the specific laboratory studies listed are not required, but a relevant work-up should be performed in order to direct further advanced imaging appropriately.
- For follow-up imaging of diverticulitis:
  - CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary for ANY of the following:
    - acute diverticulitis if symptoms or elevated WBC persists despite treatment
    - diverticulitis treated with radiologic intervention (e.g., drainage procedure)
    - complicated diverticulitis, including confirmed abscess, fistulae, free fluid, or perforation. (See: **Abdominal Sepsis/Suspected Abdominal Sepsis) (AB-3)**
- For the evaluation of non-operative treatment of acute appendicitis:

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

  - One-time CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary for EITHER of the following:
    - symptoms suspicious for recurrent appendicitis OR
    - post non-operative treatment follow-up
- For the evaluation of splenic etiologies such as suspected infarct or abscess (severe pain and tenderness, fever, history of atrial fibrillation):
  - CT Abdomen without and with contrast or with contrast (CPT® 74170 or CPT® 74160)
- For the evaluation of suspected small or large bowel etiologies (e.g., ischemia, obstruction, volvulus, or perforation):
  - CT Abdomen with contrast (CPT® 74160) or CT Abdomen and Pelvis with contrast (CPT® 74177)
- For the evaluation of suspected gastroenteritis and/or enterocolitis in the presence of any red flag findings:
  - CT Abdomen and Pelvis with contrast (CPT® 74177)
    - If no red flag findings are present, initial evaluation should include history and physical exam, as well as relevant laboratory testing and/or abdominal x-ray.
    - For suspected ischemic enterocolitis, see: **Mesenteric Ischemia (AB-6.1)** or **Colonic Ischemia (Including Ischemic Colitis) (AB-6.2)**
    - For known or suspected IBD, see: **IBD (Crohn's Disease or Ulcerative Colitis) (AB-23.1)**
- For pain described as pelvic, see: **Pelvic Pain/Dyspareunia, Female (PV-11.1)**, **Male Pelvic Disorders (PV-19.1)** or other appropriate sections based on likely etiology.

CPT® Codes for Abdominal Pain (AB-2.2)			
CPT® 74150	CT Abdomen without contrast	CPT® 76700	Ultrasound, complete Abdomen
CPT® 74160	CT Abdomen with contrast	CPT® 76705	Ultrasound, limited Abdomen
CPT® 74176	CT Abdomen and Pelvis without contrast	CPT® 76830	Ultrasound, Transvaginal
CPT® 74177	CT Abdomen and Pelvis with contrast	CPT® 76856	Ultrasound, complete Pelvis
CPT® 74181	MRI Abdomen without contrast	CPT® 72195	MRI Pelvis without contrast

CPT® Codes for Abdominal Pain (AB-2.2)			
CPT® 74183	MRI Abdomen without and with contrast	CPT® 72197	MRI Pelvis without and with contrast

Evidence Discussion

There are many potential causes of abdominal pain. Standard-of-care evaluation generally begins with complete history, physical examination, and directed laboratory testing. The initial approach establishes differential diagnoses and clinical options. It also clarifies what imaging modality and body region are medically necessary to achieve the highest diagnostic yield while reducing radiation exposure and overutilization.[1,3,5]

In the absence of red flags, Abdominal and/or Pelvic ultrasound is generally cost effective when performed early in the diagnostic paradigm. Although image quality may degrade due to overlying gas in the gut, US offers advantages in that it requires no contrast agents nor radiation exposure, can be used in pregnancy, and is readily available in evaluation of most conditions manifesting with abdominal pain. [1,3,5]

Per ASCRS, colonic endoscopic evaluation is recommended to confirm the diagnosis after resolution of acute diverticulitis to exclude malignancy, especially when initial CT scan supports abscess, shouldering, or shelf-like appearance of a presumed inflammatory mass, obstruction, mesenteric or retroperitoneal adenopathy.[18]

Non-operative treatment of acute appendicitis offers a unique imaging opportunity. CT Abdomen and Pelvis with contrast is preferred to assess post-treatment response, to identify coexisting pathology masked by appendiceal inflammation, and when surgery is considered for symptoms that recur or fail to improve due to progression of disease or complications.[7]

Advanced imaging is further warranted, especially in follow-up to non-diagnostic ultrasound, when both acute and non-acute signs and symptoms pose a diagnostic and therapeutic challenge. The optimal choice of imaging modality is guided by contemporary medical literature and specialty societal recommendations.

- CT imaging of the Abdomen and Pelvis provides high diagnostic value as initial imaging in red flag circumstances and/or in follow-up when serial imaging is necessary as defined by guidelines or ultrasound is indeterminate. CT imaging can characterize gut-related urgencies including, but not limited to, bowel blockage, abdominal ischemia, and obstructing tumors. CT is highly sensitive for acute inflammatory conditions, such as diverticulitis and appendicitis. CT offers relatively brief imaging acquisition times but requires use of ionizing radiation typically in combination with intravenous contrast, making it non-ideal in pregnant individuals.[3,5,7]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- MRI is typically reserved for pregnant individuals when ultrasound proved non-diagnostic. MRI is also relatively contraindicated for individuals who cannot tolerate confined space, long image acquisition times, and loud repetitive noise. Relative to evaluation of abdominal pain, the American College of Radiology opined "MRI is less sensitive for extraluminal air and urinary tract calculi, is more time-consuming to perform, and requires an active screening process for indwelling devices and metal, and more subject to motion artifacts in symptomatic individuals."[3,5,7]

Right Upper Quadrant and Epigastric Pain (AB-2.3)

AB.AP.0002.3.A
v1.0.2026

- The presence of any red flag findings per **General Guidelines (AB-1.0)** precludes adjudication based on any other criteria.
- For pregnant individuals, see: **Pregnancy Considerations for Imaging (AB-1.12)**
- For the evaluation of right upper quadrant pain in the absence of red flag findings:
  - Abdominal ultrasound (complete or limited) (CPT® 76700 or CPT® 76705) is the initial diagnostic test
  - CT Abdomen with contrast (CPT® 74160) or MRCP/MRI (MRI Abdomen without or without and with contrast) (CPT® 74181 or CPT® 74183) if ultrasound is equivocal or nondiagnostic
- For the evaluation of epigastric pain or dyspepsia in the absence of red flag findings:
  - Ultrasound Abdomen (CPT® 76700 or CPT® 76705) to assess for biliary/ pancreatic disease is the initial study
  - CT Abdomen with contrast (CPT® 74160) or MRI Abdomen without and with contrast (CPT® 74183), or MRCP (CPT® 74181 or CPT® 74183), is medically necessary to further evaluate non-diagnostic findings on ultrasound
  - CT Abdomen with contrast (CPT® 74160), or MRI Abdomen without and with contrast (CPT® 74183) is medically necessary for persistent symptoms after a negative or inconclusive ultrasound as well as ONE of the following:
    - Test and treat for Helicobacter pylori (H. pylori) and a trial of acid suppression with a proton pump inhibitor (PPI) for 4-8 weeks if eradication is successful, but symptoms do not resolve OR
    - An empiric trial of acid suppression with a PPI for 4-8 weeks
- Hepatobiliary System Imaging (HIDA) with OR without pharmacologic intervention (CPT® 78226 or CPT® 78227) is medically necessary for ANY of the following:
  - If there is right upper quadrant pain or epigastric pain and there is a suspicion of gallbladder disease, with a normal, or equivocal or non-diagnostic recent ultrasound, CT, or MRI
    - If findings on US suggest acute cholecystitis in a symptomatic individual (presence of gallstones with gallbladder wall thickening, Murphy's sign, and peri-cholecystic fluid) then a HIDA scan is generally not medically necessary.
    - If the HIDA without pharmacologic intervention (CPT® 78226) is initially performed and is normal or inconclusive, the site can convert the study to HIDA with pharmacologic intervention (CPT® 78227). The member will not need to return for a second study with injection of a pharmaceutical.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Suspected bile leak after trauma or surgery
- Monitoring of liver regeneration
- Assessment of liver transplant
- Assessment of choledochal cyst
- Pre-operative assessment prior to partial hepatectomy
- Chronic acalculous cholecystitis
- Biliary dyskinesia
- Functional gallbladder disease
- Sphincter of Oddi dysfunction

Special Considerations for Suspicion of Pancreatic Cancer

CT Abdomen with contrast (CPT® 74160), CT Abdomen and Pelvis with contrast (CPT® 74177), or MRI Abdomen without and with contrast (CPT® 74183) is appropriate for suspicion of pancreatic cancer in individuals aged ≥60 years with weight loss and any ONE of the following:

- diarrhea
- back pain
- abdominal pain
- nausea
- vomiting
- constipation
- new onset diabetes
- abnormal lab results raising the possibility of pancreatic cancer (e.g., elevated CA 19-9, GGTP, alkaline phosphate, or bilirubin)
- non-diagnostic or negative prior US

If none of the above signs or symptoms applies, follow criteria for epigastric pain and dyspepsia.

See also: **Pancreatic Cancer-Suspected Diagnosis (ONC-13.2)** in the Oncology Imaging Guidelines

Evidence Discussion

Many specific conditions may manifest with pain in the right upper abdominal quadrant and/or epigastrium. Dyspepsia is common and often best evaluated by empiric response to acid suppression therapy, assessment of treatment efficacy when H.Pylori is identified, and endoscopy.[2,4,6,7]

For non-peptic causation of right upper and epigastric abdominal pain, ultrasound is the initial imaging study. Ultrasound is a readily available modality that offers good diagnostic utility while eliminating exposure to ionizing radiation. Ultrasound when

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

diagnostic may confirm diagnoses of biliary and/or pancreatic disease, of space-occupying lesions, and of vascular concerns.[2,4,6,7]

When indeterminate, ultrasound may help direct what advanced imaging modality and contrast is medically necessary—e.g., MRCP/ERCP for dilated biliary ducts, CT for pancreatitis, MRI/CT with and without contrast to better characterize abdominal mass lesions. While CT is highly sensitive for acute inflammatory conditions and offers relatively brief image acquisition times, it requires use of ionizing radiation. MRI is typically reserved for pregnant individuals when ultrasound proved non-diagnostic but is relatively contraindicated for individuals who cannot tolerate confined space, prolonged image acquisitions, loud repetitive noise. Relative to evaluation of abdominal pain, the American College of Radiology opined "MRI is less sensitive for extraluminal air and calculi, is more time-consuming to perform, and requires an active screening process for indwelling devices and metal, and more subject to motion artifacts in symptomatic individuals."[2,4,6,7]

Hepatobiliary System Imaging (HIDA) with radionuclide uptake and scan in suspected hepatic, biliary, and pancreatic disease may add prognostic and functional information when ultrasound is inconclusive. HIDA scan has particular pre-operative value in the setting of gallbladder dysfunction, bile leaks, and choledochal cyst.[2,4,6,7]

Abdominal Sepsis/Abscess (AB-3.1)

AB.AS.0003.1.A

v1.0.2026

- The presence of any red flag findings per **General Guidelines (AB-1.0)** precludes adjudication based on any other criteria.
- For abdominal symptoms associated with fever and/or elevated white blood cell count ANY of the following are medically necessary:
  - CT Abdomen with contrast (CPT® 74160)
  - CT Pelvis with contrast (CPT® 72193)
  - CT Abdomen and Pelvis with contrast (CPT® 74177)
- For intraperitoneal abscess:
  - CT Abdomen and Pelvis with contrast (CPT® 74177)
    - Interval imaging as requested
- For follow-up imaging of known abnormal fluid collections after medical management or catheter drainage, ANY of the following are medically necessary:
  - Serial Ultrasound (CPT® 76705)
  - CT Abdomen with contrast (CPT® 74160)
  - CT Pelvis with contrast (CPT® 72193)
  - CT Abdomen and Pelvis with contrast (CPT® 74177)
    - The interval can be days, weeks, or months based on the clinical course of the individual

Evidence Discussion

- Individuals presenting with potential abdominal sepsis or an abscess represent an urgent clinical concern. Therefore, individuals exhibiting abdominal symptoms accompanied by fever or an elevated WBC count (or any red flag) should proceed directly to advanced imaging without further evaluation. A CT scan of the abdomen and/or pelvis with contrast is typically the appropriate study for such evaluations.[2]
- Interval imaging may be medically necessary for abscesses or other fluid collections, particularly after catheter drainage. Both ultrasound and CT imaging are appropriate for serial imaging. The timing of serial imaging is not specified and should be based on the individual's unique clinical course.[1]

Ultrasound (AB-4.0)

AB.US.0004.0.A

v1.0.2026

- For the evaluation of flank pain and/or suspected renal or ureteral calculi, retroperitoneal ultrasound (CPT® 76770 or CPT® 76775) is medically necessary in place of CT Abdomen and Pelvis for any initial or follow-up indications, if requested by provider.

Proprietary Information of UnitedHealthcare.

Suspected Renal/Ureteral Stone(s) (AB-4.1)

AB.US.0004.1.A
v1.0.2026

- CT Abdomen and Pelvis without contrast (CPT® 74176) is medically necessary for ANY of the following:
  - Suspected renal/ureteral stone with symptoms in non-pregnant adults (flank pain/ renal colic) OR
  - Suspected staghorn calculi
- CT Abdomen and Pelvis without contrast (CPT® 74176) or CT Urogram (CPT® 74178) is medically necessary for the following:
  - Suspicion renal/ureteral stones (flank pain/renal colic) with hematuria
- Ultrasound (CPT® 76770 or CPT® 76775) or MRI Abdomen and Pelvis without contrast (CPT® 74181 and CPT® 72195) is medically necessary for the following:
  - Suspected renal/ureteral stone in pregnant individuals (flank pain/renal colic)
    - The use of gadolinium contrast agents is contraindicated during pregnancy unless the specific need for that procedure outweighs risk to the fetus.
- Suspected renal/ureteral stone in children (flank pain/renal colic)
  - See: **Flank Pain, Renal Stone (PEDAB-4)** in the Pediatric Abdomen Imaging Guidelines

Evidence Discussion

Non-contrast CT (NCCT) is the imaging study of choice for initial evaluation of individuals with acute onset of flank pain and suspicion of stone disease without known prior stone disease. Non-contrast CT (NCCT) can reliably characterize the location and size of an offending ureteral calculus, identify complications, and diagnose alternative etiologies of abdominal pain. For individuals with known disease and recurrent symptoms of urolithiasis, NCCT remains the test of choice for evaluation.[17]

Although less sensitive in the detection of stones, ultrasound may have a role in evaluating for signs of obstruction. Radiography potentially has a role, although has been shown to be less sensitive than NCCT.[1]

In pregnancy, given radiation concerns, ultrasound is recommended as the initial modality of choice with potential role for non-contrast MRI.[4]

In scenarios where stone disease is suspected and initial NCCT is inconclusive, contrast-enhanced imaging, either with MRI or CT/CT Urogram may be medically necessary.[17]

Observation of Known Renal/Ureteral Stone(s) (AB-4.2)

AB.US.0004.2.A
v1.0.2026

- Radiopaque Stones
  - Initial follow-up imaging:
    - Retroperitoneal ultrasound (CPT® 76770 or CPT® 76775) and KUB X-ray
  - Subsequent follow-up imaging:
    - If initial follow-up ultrasound and KUB are negative, and there is no hematuria and individual is asymptomatic:
      - See: **Annual Surveillance (AB-4.4)**
    - If initial follow-up ultrasound and KUB demonstrates hydronephrosis, retained stone, or if the individual has persistent hematuria, or is symptomatic:
      - CT Abdomen and Pelvis without contrast (CPT® 74176)
- Non-radiopaque Stones (i.e. radiolucent)
  - Initial follow-up imaging:
    - CT Abdomen and Pelvis without contrast (CPT® 74176)
  - Subsequent follow-up imaging:
    - If CT is negative:
      - See: **Annual Surveillance (AB-4.4)**
    - If CT demonstrates a retained stone, hydronephrosis, or if the individual is being evaluated for surgery:
      - Further imaging can be considered on an individual basis
- ANY of the following are medically necessary for surgical/procedural evaluation of staghorn calculi:
  - CT Abdomen and Pelvis (contrast as requested)
  - 3-D reconstruction (CPT® 76377 or CPT® 76376)
  - Nuclear kidney imaging (CPT® 78707, CPT® 78708, or CPT® 78709) when there is concern for a poorly functioning kidney

Background and Supporting Information

- Radiopaque versus radiolucent stones on plain radiograph:
  - Radiopaque
    - Calcium-based stones (70-80%)
    - Struvite stones (triple phosphate) (usually opaque but variable – 15-20%)
  - Radiolucent

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Uric acid (5-10%)
- Cystine (1-3%)
- Medication stones (e.g. indinavir) (1%)

Evidence Discussion

Serial imaging can be used to follow the progress of a passing stone and might also be used by the urologist and/or nephrologist as they monitor non-obstructing stones for growth. No evidence was found on the optimum frequency of imaging in people who have or have had renal or ureteric stones.[15]

Non-contrast CT of the abdomen and pelvis consistently provides the most accurate diagnosis but also exposes individuals to ionizing radiation. Traditionally, ultrasonography has a lower sensitivity and specificity than CT but does not require use of radiation. However, when these imaging modalities were compared in a randomized controlled trial they were found to have equivalent diagnostic accuracy. Both modalities have advantages and disadvantages. Kidney, ureter, bladder (KUB) plain film radiography is most helpful in evaluating for interval stone growth in individuals with known stone disease and is less useful in the setting of acute stones. MRI provides the possibility of 3D imaging without exposure to radiation, but it is costly and currently stones are difficult to visualize.[16]

Follow-up imaging for asymptomatic individuals with radiopaque stones should be with retroperitoneal ultrasound and plain film radiography. Follow-up for radiolucent stones, hydronephrosis or retained stone on ultrasound, or symptomatic individuals, non-contrast CT is medically necessary.[16]

Individuals with staghorn calculi who are being considered for surgery, CT Abdomen and Pelvis (any contrast level), with or without 3-D reconstruction can be performed. Additionally, nuclear imaging may be medically necessary when there is concern for poor kidney function.[12]

Follow-Up of Treated Renal/Ureteral Stone (AB-4.3)

AB.US.0004.3.A
v1.0.2026

- Post-shock wave lithotripsy (SWL):
  - Retroperitoneal ultrasound (CPT® 76770 or CPT® 76775) is the appropriate initial follow-up imaging.
  - Retroperitoneal ultrasound (CPT® 76770 or CPT® 76775) and/or CT Abdomen and Pelvis (contrast as requested) is medically necessary for ANY of the following:
    - Individuals who are symptomatic
    - Individuals with hydronephrosis
    - Individuals who have residual fragments
  - Individuals treated by SWL who have passed fragments, are asymptomatic, and without hydronephrosis can be followed according to **Annual Surveillance (AB-4.4)**.
- Post-medical expulsive therapy (MET):
  - Retroperitoneal ultrasound is medically necessary for individuals treated by MET who have passed a stone and are symptomatic
  - CT Abdomen and Pelvis (contrast as requested) is medically necessary if hydronephrosis is demonstrated with ultrasound
  - Individuals treated by MET who have passed a stone and are asymptomatic can be followed according to **Annual Surveillance (AB-4.4)**.
- Post-ureteroscopic extraction with an intact stone:
  - Retroperitoneal ultrasound is medically necessary for individuals without symptoms.
  - CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary for individuals with symptoms or hydronephrosis demonstrated on ultrasound.
  - Individuals without symptoms or without hydronephrosis demonstrated on ultrasound can be followed according to **Annual Surveillance (AB-4.4)**.
- Post-ureteroscopic extraction requiring fragmentation of the stone(s):
  - Retroperitoneal ultrasound is medically necessary for individuals without symptoms.
  - CT Abdomen and Pelvis without contrast (CPT® 74176) is medically necessary for individuals without symptoms, but hydronephrosis demonstrated on ultrasound.
  - Individuals without symptoms or without hydronephrosis demonstrated on ultrasound can be followed according to **Annual Surveillance (AB-4.4)**.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Retroperitoneal ultrasound and KUB for individuals with symptoms and a radiopaque stone
  - CT Abdomen and Pelvis without contrast (CPT® 74176) is medically necessary for individuals with symptoms and a non-radiopaque stone.
- Post-surgical/procedural treatment of staghorn calculi:
  - CT Abdomen and Pelvis without contrast (CPT® 74176)
  - Retroperitoneal ultrasound and/or CT Abdomen and Pelvis (contrast as requested) is medically necessary for individuals with persistent symptoms and/or hydronephrosis.

Evidence Discussion

Following treatment for renal stones, retroperitoneal ultrasound is the recommended initial modality for follow-up. CT scan is medically necessary in individuals with symptoms or if hydronephrosis identified on ultrasound. Ultrasound is subsequently recommended for annual surveillance in asymptomatic individuals.[7]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Annual Surveillance (AB-4.4)

AB.US.0004.4.A

v1.0.2026

- Annual surveillance is medically necessary for stable individuals with a history of stones to assess for stone growth or formation of new stones:
  - Plain x-ray (KUB) is medically necessary for individuals with radiopaque stones.
  - Retroperitoneal ultrasound (CPT® 76770 or CPT® 76775) is the preferred modality for individuals with non-radiopaque stones.

Evidence Discussion

Plain x-ray is cost-effective and readily available for surveillance of radiopaque stones. Ultrasound is preferred for most individuals with radiolucent stones. One year imaging interval is recommended for stable individuals, but this may be tailored on stone activity or clinical signs.[7]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Nuclear Kidney Imaging (AB-4.5)

AB.US.0004.5.A

v1.0.2026

- Nuclear kidney imaging (CPT® 78707, CPT® 78708, or CPT® 78709) is medically necessary for the evaluation of the following:
  - Recurrent flank pain when CT and ultrasound are non-diagnostic OR
  - Prior imaging (CT or ultrasound) shows hydronephrosis and to determine if this is truly obstructive in nature

Evidence Discussion

Renal scintigraphy is used for evaluation of renal perfusion and function as well as renal anatomy. Regarding anatomy, renal scintigraphy is currently used when there is an allergy to CT or MRI contrast material.[5] The use of IV contrast in CT, as well as MRI, is avoided in cases of abnormal renal function and altered GFR. Renal scintigraphy has a role in the diagnosis of obstructive uropathy. It can be used to differentiate true obstruction from non-obstructive simulators causing urinary tract dilation. Nuclear renal scanning is also an excellent modality for the qualitative as well as quantitative assessment of renal transplant function. Because radiation exposure from renal scintigraphy is very low as compared to a CT scan, it maintains a role in the evaluation of pediatric renal anatomy whether normal, anomalous, or pathologic.[6]

Mesenteric Ischemia (AB-6.1)

AB.MI.0006.1.A
v1.0.2026

Acute Mesenteric Ischemia

- Suspicion of acute mesenteric ischemia, ONE of the following:
  - CTA Abdomen and/or Pelvis (Mesenteric) (CPT® 74175, or CPT® 74174, or CPT® 72191) (preferable), OR
  - MRA Abdomen and/or Pelvis (CPT® 72198 and/or CPT® 74185), OR
  - CT Abdomen and Pelvis with contrast (CPT® 74177)

Chronic Mesenteric Ischemia

- Suspicion of chronic mesenteric ischemia:
  - Mesenteric Artery Duplex Ultrasound (CPT® 93975 or CPT® 93976) and/or ONE of the following:
    - CTA Abdomen and Pelvis (CPT® 74174) OR
    - MRA Abdomen and Pelvis (CPT® 74185 and CPT® 72198)
- For clinical concern of median arcuate ligament syndrome, see: **Median Arcuate Ligament Syndrome, Nutcracker Syndrome and other Abdominal Vascular Compression Syndromes (PVD-18)** in the Peripheral Vascular Disease (PVD) Imaging Guidelines
- For suspicion of superior mesenteric artery syndrome, see: **Superior Mesenteric Artery (SMA) Syndrome (AB-20.4)**

Pre- and Post-Treatment for Mesenteric Ischemia

- Pre-operative evaluation, if not already performed (including prior to endovascular intervention):
  - CTA Abdomen and Pelvis (CPT® 74174)
- Post-procedure surveillance imaging following invasive treatment for mesenteric ischemia (celiac, superior mesenteric, and inferior mesenteric angioplasty with or without stenting, or mesenteric artery bypass grafting):
  - Baseline Duplex Ultrasound (CPT® 93975 or CPT® 93976) within 1 month of the procedure
  - Duplex Ultrasound (CPT® 93975 or CPT® 93976) at 6 months, 12 months, 18 months, and 24 months, then annually thereafter
  - CT Abdomen with contrast (CPT® 74160) or CT Abdomen and Pelvis with contrast (CPT® 74177) or CTA Abdomen (CPT® 74175) or CTA Abdomen and Pelvis (

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

CPT® 74174) or MRA Abdomen (CPT® 74185) and if requested, MRA Pelvis (CPT® 72198):

- For symptoms suggesting recurrent ischemia OR
- In the absence of symptoms, following a Duplex Ultrasound if, on the Duplex study:
  - Celiac axis:
    - PSV >370 cm/s or a substantial increase from the post-treatment baseline PSV (substantial increase has not been defined) or demonstration of restenosis ≥70%
  - Superior mesenteric artery:
    - PSV >420 cm/s, or a substantial increase from the post-treatment baseline PSV (substantial increase has not been defined) or demonstration of restenosis of ≥70%
  - Inferior mesenteric artery:
    - Substantial increase from the post treatment baseline PSV (substantial increase has not been defined)

Surveillance of Asymptomatic Mesenteric Artery Occlusive Disease

- Annual Mesenteric Artery Duplex Ultrasound (CPT® 93975 or CPT® 93976)

Evidence Discussion

- Mesenteric ischemia reflects decreased intestinal blood flow through the mesenteric vessels. Causes include: mesenteric artery embolism (often seen with atrial fibrillation), mesenteric artery thrombosis (typically from progressive atherosclerosis that may range from non-occlusive low flow to frank occlusion), and mesenteric vein thrombosis (commonly due to hyper-coagulable states).[5]
- Typical presentation of acute mesenteric ischemia is based on severe abdominal pain out of proportion to findings on physical exam, usually in individuals with a combination of the following risk factors: advanced age, hyperlipidemia, heart disease, hypercoagulability, renal failure, inflammatory conditions (e.g., vasculitis, pancreatitis, diverticulitis), recent vascular catheterization, substance use (e.g., tobacco smoking, cocaine).[5]
- Chronic mesenteric ischemia (CMI) is a syndrome related to inadequate blood flow, typically related atherosclerotic occlusive disease affecting the mesenteric circulation. Blood flow to the bowel is from the celiac artery, superior mesenteric artery, and inferior mesenteric artery. Ischemia may occur when there is significant disease affecting at least two of three arteries; however, symptoms related to severe disease isolated to one artery is also possible. Symptoms may be characterized by postprandial abdominal pain, "food fear," diarrhea, or weight loss. Revascularization

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

is typically recommended once CMI is diagnosed; this may be done via an endovascular approach (angioplasty and stenting) or through open reconstruction.[14]

- Duplex ultrasound provides an excellent screening tool for mesenteric artery occlusive disease. Duplex ultrasound is recommended for regular evaluation of individuals treated for mesenteric ischemia. Duplex ultrasound requires no ionizing radiation and is readily available. Duplex ultrasound findings help to determine the next most appropriate advanced imaging study if needed. Duplex ultrasound has a high negative predictive value of 99% with overall accuracy of 96% in ruling out significant stenosis.[10-13]
- CTA is recommended as an additional diagnostic tool in chronic mesenteric ischemia because it provides excellent image detail and helps to better define mesenteric lesions. Disadvantages of CTA include ionizing radiation, expense, and the need for a contrast agent.[1]
- MRA is considered an alternative modality to CTA. MRA boasts sensitivity and specificity of over 95% for detection of significant stenosis. However, it is limited in its ability to characterize degree of calcification, requires contrast administration, is not as widely available, and presents limitation in individuals with metallic implants.[12]

Colonic Ischemia (Including Ischemic Colitis) (AB-6.2)

AB.MI.0006.2.A

v1.0.2026

- If colonic ischemia is suspected in the setting of significant abdominal pain, CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary as the first imaging modality if ANY of the following:
  - rectal bleeding OR
  - moderate or severe tenderness OR
  - fever (≥101 degrees) OR
  - guarding, rebound tenderness, or other peritoneal signs OR
  - elevated WBC as per the testing laboratory's range
- Repeat imaging for asymptomatic or improving individuals, including routine post-operative imaging, is generally not medically necessary.
- CTA Abdomen (CPT® 74175) or CTA Abdomen and Pelvis (CPT® 74174) or MRA Abdomen (CPT® 74185) AND if requested, MRA Pelvis (CPT® 72198) is medically necessary for the suspicion of right sided or pancolonic ischemia (per the initial CT Abdomen and Pelvis).

Background and Supporting Information

- Suspicion of colonic ischemia based on sudden cramping abdominal pain accompanied by urgency to defecate and passage of bright red blood, maroon blood, or bloody diarrhea, with risk factors including cardiovascular disease, diabetes mellitus, kidney disease, previous abdominal surgery, use of constipating medications, COPD, and atrial fibrillation.

Evidence Discussion

- Based on ACG Clinical Guideline: "In contrast to AMI (acute mesenteric ischemia) in which conventional mesenteric angiography or CTA plays an essential role, vascular imaging studies are not medically necessary in most individuals with suspected CI (colonic ischemia) because by the time of presentation, colon blood flow has usually returned to normal and the observed changes are not from ongoing ischemia but rather reflect the ischemic insult with or without reperfusion injury."[4]
- CT scan is recommended as first-line imaging for individuals with ischemic colitis. CT allows for identification and/or exclusion of other causes of abdominal pain; may suggest diagnosis of colonic ischemia, including distribution of disease; and may allow assessment of disease severity.[4]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- CT-angiogram (CTA) is generally not medically necessary, since in most cases, blood flow has returned to normal by the time of clinical presentation. CTA may be helpful in distinguishing between acute mesenteric ischemia (AMI) and ischemic colitis. In diagnosing AMI, sensitivity and specificity are reported to be over 90%. Isolated right sided colonic ischemia (IRCI) carries a worse prognosis than other distributions of colitis and may represent evidence of significant SMA disease; as such, CTA is medically necessary to fully evaluate the vasculature and potentially prevent catastrophic associated complications.[4]
- Radiation and contrast related complications are risks associated with CT and CTA.[11]
- MRA also allows for evaluation of the proximal celiac artery and SMA. Advantages include high sensitivity and specificity. Disadvantages include poor visualization of distal vessels and non-occlusive ischemia, long acquisition times, and motion susceptibility artifact which could potentially delay treatment. In contrast to CTA, MRA is "less likely to show ischemic findings within the bowel itself."[11]
- Alternative imaging studies include non-contrast CT scan, ultrasound, and barium enema:
  - Non-contrast CT scan – there is a lack of literature related to this imaging modality; however, signs of ischemia, including evaluation of bowel and vasculature, rely on use of contrast.[11]
  - Ultrasound – Experience "in the setting of CI is very limited;" also, there is a low specificity, high false negative rate.[4]
  - Duplex US (arterial study) – there may be a role; however, various factor, including difficulty evaluating distal vessels and non-occlusive ischemia, as well as acquisition time, and individual discomfort limit utility in evaluating for acute mesenteric ischemia.[11]
  - Barium enema – originally described in diagnosis of CI in the 1960s. There is a very limited role today, as CT and colonoscopy are preferred. Modern usage is mainly to follow ischemic strictures in a chronic setting.[4]

Post-Op Pain and/or Complication Within 60 Days (AB-7.1)

AB.OP.0007.1.A

v1.0.2026

- CT Abdomen and/or Pelvis with contrast (CPT® 74177, or CPT® 74160, or CPT® 72193) is medically necessary for suspected post-operative/post-procedure complications (e.g., bowel obstruction, abscess, anastomotic leak, or post-endoscopic complication).
- Beyond 60 days post-operatively, see: **Abdominal Pain (AB-2)**.
- For liver post-transplant indications and imaging, see: **Liver Transplant, Post-Transplant Imaging (AB-42.3)**
- For kidney post-transplant indications and imaging, see: **Kidney Transplant, Post Transplant (AB-42.6)**
- For suspected ureter or bladder injury indications and imaging, see **Ureteral and/or Bladder Trauma of Injury (PV-25.1)**

Evidence Discussion

Early investigation with advanced imaging is medically necessary to identify post-operative/post-procedural complications. Most complications manifest within the first 2 months.[1,2]

CT imaging is the mainstay for abdominal imaging in the post-operative period due to its high resolution and speed. It is particularly effective at identifying abdominal fluid collections in the peri-hepatic and peri-splenic areas, as well as in the pelvis. CT may also differentiate between post-operative seromas, hematomas, and abscesses, aiding in the drainage of these collections. The use of contrast is recommended to enhance diagnostic accuracy. Abdominal Lymphadenopathy (AB-8.1)

AB.AL.0008.1.A
v1.0.2026

- History of malignancy
  - Refer to oncology guidelines specific for known malignancy
  - Biopsy may be considered
- For suspected lymphoproliferative disorder:
  - Imaging modality for biopsy is at the discretion of the interventional radiologist
    - Imaging studies performed as part of a CT-, MR-, or Ultrasound-guided procedure should be reported using appropriate CPT® codes, see: **CT-, MR-, or Ultrasound-Guided Procedures (Preface-4.2)**
  - PET/CT (CPT® 78815) is medically necessary prior to biopsy in order to determine a more favorable site for biopsy, when a prior biopsy was nondiagnostic, or a relatively inaccessible site is contemplated which would require invasive surgical intervention for biopsy attempt.
- If clinical, laboratory findings, biopsy, or PET suggest benign etiology, and no history of malignancy:
  - First follow-up imaging at 3 months
    - CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary
  - Additional follow-up imaging at 6 and 12 months, if no improvement at 3 months
    - CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary
  - Further imaging is NOT medically necessary if clinically significant changes are not seen within one year of follow-up imaging.
- If a follow-up CT demonstrates a concerning change, biopsy should be performed.
  - If biopsy is inconclusive, PET/CT (CPT® 78815) is medically necessary

Evidence Discussion

Abdominal lymphadenopathy can be associated with infectious, autoimmune, and malignant etiologies.[12] Lymph node size is a key indicator of potential malignancy. Lymph nodes exceeding 10 mm in short-axis diameter are generally considered suspicious, particularly in individuals with a history of cancer or systemic symptoms. Whenever possible, tissue pathology is preferred in the diagnosis of enlarged lymph nodes.[13]

CT remains the main modality for evaluation of intra-abdominal lymph nodes. This can be used for identification, follow-up, and guidance for percutaneous biopsy. Serial CT should be done with consideration of radiation exposure.[6,12]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

PET/CT, although not specific for malignancy, can assist in identifying alternate sites for biopsy in individuals with a previously non-diagnostic biopsy or when lymph nodes are relatively inaccessible and biopsy would require an invasive surgical intervention.[9]

Inguinal Lymphadenopathy (AB-8.2)

AB.AL.0008.2.A
v1.0.2026

There is no evidence-based support for advanced imaging of clinically evidenced isolated inguinal lymphadenopathy without biopsy. Advanced imaging should be directed by results of biopsy. If biopsy results are negative or benign, then advanced imaging is not medically necessary.

- High suspicion of lymphoma: See **Non-Hodgkin Lymphomas (ONC-27)** and **Hodgkin Lymphoma (ONC-28)** in the Oncology Imaging Guidelines
- Prior history of malignancy: See **Metastatic Cancer, Carcinoma of Unknown Primary Site, and Other Types of Cancer (ONC-31)** in the Oncology Imaging Guidelines
- If biopsy is positive for malignancy, advanced imaging is guided by sections specific to the histological diagnosis.

Background and Supporting Information

- Localized inguinal lymphadenopathy should prompt:
  - search for adjacent extremity injury or infection
  - 3 to 4 weeks of observation if clinical picture is benign
  - excisional or image guided core needle biopsy under ultrasound or CT guidance of most abnormal lymph node if condition persists or malignancy suspected
- Generalized inguinal lymphadenopathy should prompt:
  - diagnostic work-up, including serological tests, for systemic diseases and
  - excisional or image guided core needle biopsy under ultrasound or CT guidance of most abnormal lymph node if condition persists or malignancy suspected

Evidence Discussion

Inguinal adenopathy is benign and self-limited in most individuals. History and physical alone can often identify the cause of the adenopathy. Biopsy remains the primary diagnostic tool in evaluation of undiagnosed inguinal adenopathy. This can be done with fine needle aspiration or core needle biopsy. Diagnostic rates can be improved with the use of ultrasound.[7]

There is no evidence-based support for advanced imaging of inguinal adenopathy in the absence of biopsy results that would direct that imaging. If benign, no further work-up is necessary.

Click Here to Return to the Main TOC

Sclerosing Mesenteritis and Mesenteric Panniculitis (AB-8.3)

AB.AL.0008.3.A

v1.0.2026

- For new or worsening clinical symptoms with a diagnosis of sclerosing mesenteritis or mesenteric panniculitis:
  - CT Abdomen and Pelvis without and with contrast (CPT® 74178) is medically necessary
- Requests for follow-up imaging in asymptomatic individuals or for sequential imaging to monitor for the development of malignancy is based upon size of lymph nodes:
  - Asymptomatic individuals with lymph nodes less than 10mm meet medical necessity for annual CT Abdomen and/or Pelvis with and without contrast OR MRI Abdomen and/or Pelvis with and without contrast for 2 consecutive years to ensure benign stability.
  - If lymph nodes are greater than or equal to 10mm, PET/CT (CPT® 78815) or biopsy is considered medically necessary.

Background and Supporting Information

- Sclerosing mesenteritis and mesenteric panniculitis are rare, incompletely understood entities that are characterized by an idiopathic inflammatory condition of the mesentery. The diagnosis is typically suggested by characteristic radiologic findings known as Coulier's criteria. To support the diagnosis, at least three of the five criteria should be met including:
  - mesenteric mass that encases or displaces adjacent structures without evidence of direct invasion
  - increased attenuation of mesenteric fat (hyperattenuating fat)
  - presence of soft-tissue nodules or mesenteric lymph nodes with the affected area
  - fatty halo (low-attenuation ring) surrounding lymph nodes or mesenteric vessels
  - hyperattenuating pseudocapsule encasing the mesenteric lesion
- Sclerosing mesenteritis may represent a spectrum of diseases (e.g., retractile mesenteritis, mesenteric panniculitis, and mesenteric lipodystrophy) or may be stages of one disease with progression.
- The chronic inflammation may result in fibrosis with a mass effect and can involve the gut (causing obstruction), the mesenteric vessels, and other intra-abdominal or retroperitoneal organs. The etiology is uncertain but may be secondary to trauma (previous abdominal surgery), an autoimmune process, ischemia, infection, and possibly may represent a paraneoplastic syndrome secondary to a malignancy, though this is controversial.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- There is an increased prevalence of malignancy in individuals with sclerosing mesenteritis, and this has resulted in requests for sequential imaging in stable or asymptomatic individuals. In addition, requests may be made to assess the clinical response in those undergoing active treatment.
- However, studies have reported that the data on potentially developing a subsequent malignancy is inconclusive and thus “it does not seem justified to subject individuals with mesenteric panniculitis, especially those in whom other associations such as abdomino-pelvic surgery may explain the mesenteric panniculitis findings, to multiple follow-up CT scans with the aim of detecting a future malignancy.”
- In addition, there is no correlation between radiologic and clinical findings, and management decisions are guided by the severity and type of symptoms. Thus, sequential radiologic imaging to assess treatment response is not recommended.

Evidence Discussion

Recommendation for follow-up imaging in individuals with suspected malignancy-associated conditions vary significantly, ranging from no imaging to annual examination over five years. While some meta-analyses show no detectable increase in cancer risk, other studies suggest a slight long-term increased risk of lymphoma in individuals without initial malignancy indicators, with most cases detected within the first year. Imaging is also used to monitor inflammation progression, although data remains limited. In general, individuals with stable disease and no radiologic progression after two years do not require frequent imaging. However, if new suspicious features arise, such as significant growth in mesenteric masses or new lymphadenopathy, a biopsy is advised. For asymptomatic individuals without initial signs of malignancy, annual CT scans for two years are recommended to ensure disease stability, and thereafter performed for concerning symptoms.[10]

CT scan of the Abdomen and Pelvis is the preferred modality in the diagnosis of new or worsening symptoms. [11]

Bariatric Post-Operative Complications (AB-9.1)

AB.BS.0009.1.A
v1.0.2026

- For the evaluation of post-operative complications:
  - CT Abdomen and Pelvis with contrast (CPT® 74177), CT Abdomen with contrast (CPT® 74160), or CTA Abdomen and Pelvis (CPT® 74174) is medically necessary for individuals who have had weight loss surgery and present with suspected complications evidenced by:
    - nausea or vomiting OR
    - abdominal pain/tenderness OR
    - fever OR
    - abdominal distension OR
    - suspected hernia
- Internal hernias in individuals who have had Roux-en-Y gastric bypasses may have intermittent and relatively mild abdominal symptoms which require immediate evaluation with CT imaging.
- See: **Post-Operative Pain Within 60 Days Following Abdominal Surgery – Abdominal Procedure (AB-7)**

Background and Supporting Information

- Bariatric procedures include gastric banding, gastric bypass, sleeve gastrectomy, and biliopancreatic diversion procedures.

Evidence Discussion

- Pre-operative assessment:[4,11,16]
  - In individuals with previous surgery of the foregut, imaging may be medically necessary for surgical planning. This is addressed in **Abdomen Imaging Guidelines: General Guidelines (AB 1.0)** under pre-operative radiology imaging. "If imaging is requested by the operating surgeon to support planned surgery, the imaging may be approved."
  - Routine use of preoperative advanced imaging is considered "usually not appropriate" by the American College of Radiology ACR Appropriateness Criteria® for Preoperative and Postoperative Imaging for Bariatric Procedures.
- Post-operative complications:
  - Bariatric surgery can result in numerous complications that may not be apparent after initial evaluation or ultrasound. These include internal hernias, marginal

Click Here to Return to the Main TOC

ulceration, intussusception, stenosis, perforations, and leaks. A systematic review of splenic complications showed that splenic abscess and splenic infarct were the most common splenic complications.[12] Symptoms concerning for complications include weight loss failure, heartburn, nausea and vomiting, abdominal pain, fever, abdominal distention, abdominal tenderness, leukocytosis, and suspicion of a hernia.[12]

- CT is highly sensitive in the setting of symptomatic patients with suspected complications and is considered the gold standard imaging.[12,14,15,16] Contrast is helpful to evaluate for anastomotic leaks.[16]
- CTA is a useful imaging option for post-operative complications where blood supply is potentially compromised, such as suspected splenic infarct.[13]
- Internal hernias in individuals who have had Roux-en-Y gastric bypasses may have intermittent and relatively mild abdominal symptoms which require immediate evaluation with CT imaging.[17]
- Though abdominal pain in post-operative bariatric individuals may be gallbladder induced and an ultrasound would be helpful for this diagnosis, the complications of bariatric surgery can become quickly life-threatening, so any request for CT imaging in the post-operative bariatric individual should not be delayed with recommendations for ultrasound, even if the examination does not indicate any signs or symptoms of more serious or complicated disease.[4,10,11]

Percutaneous Gastrostomy (AB-9.2)

AB.BS.0009.2.A
v1.0.2026

- Percutaneous Endoscopic Gastrostomy (PEG)
  - CT Abdomen with or without contrast (CPT® 74160 or 74150) is medically necessary:
    - For pre-operative assessment in the presence of:
      - abdominal wall defects such as an open abdomen OR
      - the presence of “ostomy” sites or drain tubes OR
      - abdominal surgical scars or prior major abdominal surgery (e.g. laparotomy, laparoscopy) OR
      - known situs inversus OR
      - known paraesophageal hernia OR
      - previous endoscopic attempt did not achieve adequate transillumination through the abdominal wall or compression and a suitable site for PEG placement could not be determined
  - Percutaneous Gastrostomy via Interventional Radiologist using CT guidance
    - A pre-operative CT Abdomen with or without contrast (CPT® 74160 or 74150) is medically necessary for complicated cases in which a safe window cannot be determined via fluoroscopy.
    - See above indications for CT prior to endoscopic or surgical gastrostomy tube placement for pre-operative indications.
  - Suspected complication of an endoscopically or IR-placed gastrostomy or jejunostomy tube:
    - CT Abdomen with or without contrast (CPT® 74160 or 74150) or CT Abdomen and Pelvis with or without contrast (CPT® 74177 or 74176)

Background and Supporting Information

- A percutaneous endoscopic gastrostomy utilizes endoscopic guidance in order to place the feeding tube.
- The optimal site for gastrostomy placement is determined by illuminating the abdominal wall from the stomach using the scope and simultaneously indenting the wall with the finger and visualizing that indention endoscopically.
  - Routine CT prior to this is generally not medically necessary.
  - A study retrospectively compared complication rates between individuals who underwent a pre-procedure CT vs. those that did not and found no difference in the rate of bleeding events, need for operative intervention, or accidental tube dislodgement.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- One individual in the non-CT group had an injury due to the tube being placed through the colon, but in that case, there was failure of transillumination through the abdominal wall.
- The authors concluded, “routine CT to evaluate for unfavorable anatomy such as overlying liver or transverse colon prior to PEG tube placement does not result in a reduced complication rate. Safe site selection utilizing the correct technique of transillumination of the abdominal wall and visualization of the indentation of the operator’s finger is essential for safe PEG tube placement.”

Evidence Discussion

The use of routine pre-procedure CT scans does not result in lower complication rates for endoscopic percutaneous gastrostomy. A retrospective study comparing complication rates between individuals who underwent pre-procedure CT scans and those who did not found no difference in the rate of bleeding events, need for operative intervention, or accidental tube dislodgement. Thus, pre-procedure CT of the abdomen is reserved for complex placement scenarios.[1-9]

Post-procedure, the role of CT imaging is to assist in identifying complications, allowing fast visualization of issues such as a migrated internal bumper or injury to internal viscera.[1-9]

Click Here to Return to the Main TOC

Blunt Abdominal Trauma (AB-10.1)

AB.BA.0010.1.A

v1.0.2026

- Abdominal and/or Pelvic ultrasound (CPT® 76700 and/or CPT® 76856) is medically necessary for the evaluation of blunt abdominal trauma when requested.
- CT Abdomen and/or Pelvis with contrast (CPT® 74160, or CPT® 72193, or CPT® 74177) is medically necessary for:
  - High probability of intra-abdominal injury after blunt abdominal trauma, with new onset of ANY of the following conditions:
    - Abdominal pain or tenderness
    - Pelvic or femur fracture
    - Lower rib fracture
    - Costal margin tenderness or evidence of thoracic wall trauma
    - Diminished breath sounds
    - Vomiting
    - Pneumothorax
    - Hematocrit <30%
    - Hematuria
    - Elevated AST
    - Non-examinable individual (intoxicated, less than fully conscious, Glasgow Coma Scale Score <13, etc.)
  - Evidence of abdominal wall trauma or presence of a seat-belt sign
  - If an ultrasound demonstrates definitive abnormalities or yields inconclusive findings

Evidence Discussion

Intra-abdominal injury is an indication for ultrasound (US) and/or advanced imaging. Advanced imaging in acute trauma is generally with CT of the Abdomen and/or Pelvis with contrast. Both US and CT can be completed rapidly. CT with contrast can provide more detailed images of blood vessels and tissues, helping to better identify areas of bleeding, inflammation, or injury.[1] A seat belt sign is a linear area of bruising, abrasion or erythema across the abdomen, chest, or neck in the distribution of a seat belt. The presence of a seat belt sign is strongly associated with intra-abdominal injury.[8]

Hereditary (Primary) Hemochromatosis (HH) and Other Iron Storage Diseases (AB-11.2)

AB.GD.0011.2.A
v1.0.2026

- MRI Abdomen without contrast (CPT® 74181) for iron quantification
  - If transferrin iron saturation (TS) ≥45% OR elevated serum ferritin (males [assigned at birth] >300 ng/ml, females [assigned at birth] >200 ng/ml) **AND**
  - Genetic studies for hemochromatosis have been performed and results are ANY of the following:
    - Negative for hemochromatosis
    - C282Y/H63D compound heterozygote
    - C282Y heterozygote
    - Non-C282Y homozygote

- **Note:**

  For C282Y/C282Y homozygote, iron quantification generally not indicated. Workup is as follows:

  - If serum ferritin >1000 ug/L or elevated liver enzymes:
    - Liver biopsy for fibrosis staging and rule out concurrent liver disease
  - If serum ferritin <1000 ug/L and normal liver enzymes:
    - Therapeutic phlebotomy

    Note:

    Studies indicate that measurements of hepatic iron concentration by MRI may be more useful in ruling out than diagnosing clinically significant iron overload. MRI can distinguish between primary and secondary iron overload based on iron uptake in the reticuloendothelial system.)

- For the evaluation of suspected hepatic iron overload in chronic transfusional states (e.g., sickle cell disease, thalassemia, oncology patients, bone marrow failure, and stem cell transplant individuals):
  - MRI Abdomen without contrast (CPT® 74181) for iron quantification can be performed annually.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- See: **Transfusion-Associated (Secondary) Hemochromatosis (PEDAB-18.2)** in the Pediatric Abdomen Imaging Guidelines regarding transfusion-associated hepatic iron deposition.
- If clinical, biopsy, or radiological findings suggest advanced fibrosis or cirrhosis and HCC surveillance is requested, then follow HCC Screening Guidelines – See: **Chronic Liver Disease, Cirrhosis and Screening for HCC (AB-26.1)**.
- Role of MR Elastography (CPT® 76391):
  - The role of MR Elastography to assess the degree of fibrosis in the setting of hemochromatosis is not yet clearly defined and thus not currently considered medically necessary.

Background and Supporting Information

- An elevated serum ferritin >1000 mcg/l is associated with an increased risk of cirrhosis and mortality in C282 homozygotes, while a serum ferritin <1000 mcg/l is associated with a very low likelihood of cirrhosis.
- The role of serial MRI for monitoring hepatic iron concentration in hemochromatosis has not been defined. Treatment is phlebotomy and results are monitored by serum ferritin.
- One of the main limitations of MR Elastography is that artifact from excess iron deposition degrades signal intensity in MRE sequences, leading to technical failure of elastography and a decrease in MRE's diagnostic reliability. The latest ACG Clinical Guideline (2019) indicated that MRI for the purpose of estimating hepatic iron concentration is appropriate in the circumstances described above. However, "if there is a concomitant need to stage hepatic fibrosis, then liver biopsy is the preferred method." The ACG diagnostic algorithm for the workup of hemochromatosis does not include MR Elastography at any stage, including the evaluation for the presence, absence, or degree of fibrosis.

Evidence Discussion

The ACG Clinical Guideline indicated that MRI without contrast is the preferred modality for assessing hepatic iron concentration in iron overload conditions, including primary hereditary hemochromatosis (HH) as well as in secondary, multi-transfusion conditions, such as sickle cell disease, thalessemia, and in oncology individuals and those with bone marrow failure, in whom it can be done annually. MRI offers several key advantages. MRI can distinguish between primary and secondary iron overload based on uptake in the reticuloendothial system, is non-invasive, radiation-free, and has the ability to be performed on both liver and heart. In addition, it is useful for screening, as noted, in the appropriate populations.[9]

CT has been used but presents the negatives of radiation exposure. Dual-energy scans are required to compensate for background attenuation, so its use is reserved for individuals without access to MRI.[15]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Ultrasound-based elastography can assess the need for biopsy. However, Magnetic Resonance Elastography (MRE) is not preferred due to MRI signal degradation by excess iron and is not recommended by the ACG at any stage of the work-up.[9]

For individuals with iron indices indicative of classic HH, iron mobilized by well-controlled phlebotomy can provide an alternative estimate of total body iron comparable to liver iron quantification. Serial MRI monitoring of hepatic iron concentration has not been defined; instead, serum ferritin levels are monitored during phlebotomy.[16]

Inguinal or Femoral Hernia, or Indeterminate Groin Pain (AB-12.1)

AB.IH.0012.1.A
v1.0.2026

- Clinical examination alone is usually sufficient for confirming the diagnosis of an evident groin hernia.
- If musculoskeletal ailments such as osteitis pubis or athletic pubalgia are in the differential, see: **Joint Instability and Dysfunction (MS-30.1)** or **Muscle and Tendon Injury (MS-11.1)** in the Musculoskeletal Imaging Guidelines.
- Ultrasound, pelvic limited (CPT® 76857) or pelvic complete (CPT® 76856) is the initial imaging study if:
  - vague groin swelling with diagnostic uncertainty OR
  - poor localization of swelling (as might be seen with a small hernia and prominent overlying fat) OR
  - intermittent swelling not present on examination OR
  - other/indeterminate groin complaints without swelling
- If ultrasound is indeterminate or non-diagnostic, ONE of the following is medically necessary:
  - CT Pelvis with contrast (CPT® 72193) or without contrast (CPT® 72192)
  - MRI Pelvis without contrast (CPT® 72195) or with and without contrast (CPT® 72197)
- For suspected incarceration or strangulation (**initial ultrasound is not required**):
  - CT Pelvis with contrast (CPT® 72193) or without contrast (CPT® 72192)
- For chronic post-surgical groin pain (after hernia repair):
  - Pelvic ultrasound (CPT® 76856 or CPT® 76857) or US-guided nerve block
  - CT Pelvis with contrast (CPT® 72193) or without contrast (CPT® 72192) or MRI Pelvis without contrast (CPT® 72195) or without and with contrast (CPT® 72197) can be approved if either ultrasound or ultrasound-guided nerve block is indeterminate or non-diagnostic, to assess for other, non-neuropathic causes.

Evidence Discussion

- Diagnosis of inguinal and femoral hernias is usually possible by history and physical alone. When the diagnosis is in question because physical exam is inconclusive or symptoms are vague, ultrasound should be the initial imaging study. Ultrasound can provide useful information without the risk of radiation. It is readily available, easily performed and can be used in conjunction with provocative maneuvers such as valsalva to help delineate a hernia. These provocative maneuvers are more difficult to perform during CT scanning, which gives a more static image.[2]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- In the event of an inconclusive ultrasound or if there is a concern for a complicated hernia, imaging of the pelvis with either CT or MRI is appropriate. Abdominal imaging is not medically necessary for evaluation of an inguinal or femoral hernia.[2]
- Post-surgical pain can be associated with neuropathy, recurrence, or mesh complications. These problems should be evaluated with US and/or nerve block as well prior to proceeding to advanced imaging if these studies are indeterminate.[8]

AB.IH.0012.2.A

v1.0.2026

- For known or suspected primary or recurrent Spigelian hernia (anterior abdominal wall hernia through the semilunar line), ventral hernia, umbilical, or incisional hernia:
  - CT Abdomen without or with contrast (if at or above the umbilicus) (CPT® 74150 or CPT® 74160) OR
  - CT Pelvis without or with contrast (if below the umbilicus) (CPT® 72192 or CPT® 72193) OR
  - CT Abdomen and Pelvis without or with contrast (if above and below the umbilicus, or indeterminate) (CPT® 74176 or CPT® 74177)

Evidence Discussion

- Hernias of the abdominal wall can have a variable presentation and a challenging physical exam. In addition, there may be secondary hernias that are not noted on physical exam or the hernia may track through different layers of the abdominal wall. The size of the hernia defect is also an important consideration in determining operative approach. Ultrasound is limited in being able to evaluate size and extent of hernia through various tissue planes. Advanced imaging may be medically necessary for both diagnosis and in planning treatment. Limits to imaging only involve targeting imaging to the appropriate body region.[7]

Hiatal Hernia (AB-12.3)

AB.IH.0012.3.A

v1.0.2026

- CT Chest with contrast (CPT® 71260) and/or CT Abdomen with contrast (CPT® 74160) is medically necessary to evaluate ANY of the following:
  - For pre-operative treatment planning
  - Suspected complication of primary disease or surgery

Background and Supporting Information

- Complications of hiatal hernia may include a gastric volvulus (torsion) within the chest cavity, vomiting, chest pain, or difficulty in swallowing.

Evidence Discussion

- Hiatal hernias can become symptomatic. If so, evaluation should follow the guidelines for the specific symptom complex (such as reflux, cough, abdominal or chest pain, vomiting, dysphagia, abnormal chest x-ray, etc.).[9]
- To avoid unnecessary testing and radiation exposure, advanced imaging for hiatal hernias should be reserved for specialist requests for pre-operative evaluation or for complications of the primary disease or surgery.[9]

Abdominal Wall Mass (AB-13.1)

AB.AM.0013.1.A

v1.0.2026

- Abdominal ultrasound and/or Pelvic ultrasound (CPT® 76700 or CPT® 76705 and/or CPT® 76856) is medically necessary as the initial imaging study to assess an abdominal wall or subcutaneous mass.
- MRI Abdomen without and with contrast (CPT® 74183) or CT Abdomen with contrast (CPT® 74160) is medically necessary to further characterize a suspected malignant or indeterminate mass detected on ultrasound.
  - Pelvic imaging may be medically necessary depending on the location of the mass.

Evidence Discussion

- Mass lesions of the subcutaneous tissue and abdominal wall are generally benign and can be diagnosed through physical examination (such as lipomas, fibromas, epidermal inclusion cysts, etc.). For lesions that require imaging for further delineation, ultrasound is the initial study of choice. Ultrasound allows for real-time imaging, and the addition of Doppler techniques can help identify vascular lesions. It is highly specific for benign lesions.[1] If the ultrasound image is inconclusive, it can guide the choice of additional imaging modalities, body areas, and contrast levels.
- Subsequent or second-line imaging for indeterminate ultrasound findings includes CT with contrast or MRI with and without contrast. ACR Appropriateness Criteria® stated, "CT is widely considered fast and accurate for excluding or confirming a mass" and "may be additionally helpful in the setting of suspected hernia, congenital abnormalities, hematomas, and infections."[1] It is not necessary to perform CT without and with contrast as little diagnostic value is gained by the additional imaging without contrast.[5] MRI is particularly useful for evaluating masses that appear sarcomatous prior to biopsy. ACR stated, "Although helpful in defining relationship of masses to adjacent fascia, muscles, and vessels, MRI is often not specific enough to establish a definitive diagnosis."[1] The appropriate body region for imaging depends on the location of the mass.

Indeterminate Intra-Abdominal Mass (AB-13.2)

AB.AM.0013.2.A
v1.0.2026

- For a palpable abdominal mass on physical examination:
  - Abdominal ultrasound (CPT® 76700) and/or Pelvic ultrasound (CPT® 76856) is medically necessary in lieu of CT, if requested
  - CT Abdomen with contrast (CPT® 74160) if above the umbilicus
  - CT Abdomen and Pelvis with contrast (CPT® 74177) if extending below the umbilicus
  - CT Pelvis with contrast (CPT® 72193) if involving the pelvis
- Indeterminate findings on a prior CT or ultrasound:
  - MRI Abdomen without and with contrast (CPT® 74183)
    - MRI Pelvis without and with contrast (CPT® 72197) is medically necessary to evaluate if the mass extends below the umbilicus or involves the pelvis
- For a pulsatile abdominal mass, suspected aortic aneurysm: See: **Abdominal Aortic Aneurysm (AAA) (PVD-6.3)** in the Peripheral Vascular Disease (PVD) Imaging Guidelines.
- For females (assigned at birth) with a suspected adnexal mass or fibroid: See: **Adnexal Mass/Ovarian Cysts (PV-5)** or **Leiomyomata/Uterine Fibroids and Other Uterine Masses(PV-12)** in the Pelvis Imaging Guidelines.
- Pregnant individual:
  - Abdominal and/or Pelvic and/or Transvaginal ultrasound (CPT® 76700 and/or CPT® 76856 and/or CPT® 76830) is appropriate for initial imaging.

Evidence Discussion

- The origins and characteristics of a palpable intra-abdominal mass are difficult to determine on physical exam. For intra-abdominal masses, contrast-enhanced CT and ultrasound examination have demonstrated accuracy. Although ultrasound may be limited by body habitus or bowel gas, it offers several advantages.[1] Ultrasound requires no ionizing radiation, is cost effective, helps determine most appropriate next advanced imaging study (CT vs. MRI), is readily accessible, and often can be scheduled same day.
- ACR Appropriateness Criteria® stated, "CT demonstrated high positive predictive value (99%) and negative predictive value (97%) for determining the presence or absence of a mass and correctly identified the organ of origin in 93% of individuals with palpable abnormalities on clinical examination." (2019) MRI is useful for

Abnormal Findings on Endoscopy/ Colonoscopy (AB-13.3)

AB.AM.0013.3.A
v1.0.2026

The following criteria applies to findings on endoscopy or colonoscopy that have NOT been diagnosed or biopsy-proven as malignant. For biopsy-proven malignancy, refer to the appropriate Oncology Imaging Guideline.

- For suspicious (not clearly benign) submucosal lesion(s) noted in the stomach or small bowel or gastric extrinsic compression on colonoscopy, ONE of the following is medically necessary:
  - CT Abdomen with contrast (CPT® 74160) OR
  - CT Abdomen and Pelvis with contrast (CPT® 74177)
- For suspicious (not clearly benign) lesion(s) noted above the rectum (in the colon or small bowel), unexplained colonic extrinsic compression on colonoscopy, or pre-operative planning for complete surgical removal of a polypoid lesion the following are medically necessary,
  - CT Abdomen and Pelvis with contrast (CPT® 74177)
  - MRI Pelvis without and with contrast (CPT® 72197) or MRI Pelvis without contrast (CPT® 72195) is medically necessary in addition to CT when there is an additional suspicious lesion(s) in the distal sigmoid or rectum
- For submucosal rectal lesions or unexplained extrinsic compression in the rectum:
  - MRI Pelvis without and with contrast (CPT® 72197), or if requested, MRI Pelvis without contrast (CPT® 72195)
- For criteria specific to biopsy-proven colorectal cancer, See **Colorectal Cancer – Initial Work-up/Staging (ONC-16.2)** in the Oncology Imaging Guidelines.
- For criteria specific to biopsy-proven Gastrointestinal Stromal Tumor (GIST): See **Gastrointestinal Stromal Tumor (GIST) (ONC-12.5)** in the Oncology Imaging Guidelines.
- For criteria specific to biopsy-proven gastric cancer: See **Gastric Cancer - Initial Work-up/Staging (ONC-14.9)** in the Oncology Imaging Guidelines.

Evidence Discussion

- Endoscopic ultrasound with or without fine-needle aspiration is the preferred initial imaging modality to further characterize a gastric submucosal lesion detected on endoscopy. Rectal endoscopic ultrasound is the preferred initial imaging study to further characterize submucosal rectal lesions.[2,3]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Radiographic modalities may be warranted when endoscopic and/or rectal ultrasound cannot be performed (e.g. stricture or severe inflammatory process prohibit passage of probe, etc.), is indeterminate, findings indicate need for further characterization, there is external impression(s) against the gut wall, and/or therapeutic need to understand extent of visualized disease and/or of the origin of an endoscopically-apparent malignancy. Choice of the optimal imaging modality requires consideration of factors such as age, gender, fertility, co-morbidities, medications, and allergies.
- Ultrasound can provide high resolution imaging of the liver, gallbladder, bile ducts, pancreas, spleen, kidneys, and abdominal vasculature. It can also provide information regarding phase and direction of blood flow in arteries and veins via Duplex scanning. Ultrasound requires no ionizing radiation, is readily available being mobile, cost effective, and easier to schedule for same day testing. However, image quality may be limited due to bowel gas (a particular disadvantage in assessment of endoscopically-identified gut lesions), poor acoustic window acquisition, obesity, and sonographer experience level.
- Computed tomography (CT) of the abdomen offers excellent 3-dimensional resolution of the gut and its surrounding structures, especially when performed with use of oral and/or intravenous (IV) contrast agents. CT scan requires a significant dose of ionizing radiation but is ideally suited to characterizing lesions within the gut because the quick speed of image acquisition reduces the potential for motion artifact. The NCCN-recommended imaging of a suspected metastatic adenocarcinoma includes CT imaging of the chest, abdomen, and pelvis.[4]
- Magnetic resonance imaging (MRI) uses a magnetic field to capture excellent 3-dimensional soft tissue resolution. As with CT scans, the technique is often performed with IV contrast agents, and with specialized techniques, can be directed either at whole or parts of the abdomen or at specific abdominal structures (e.g., MR elastography of liver, MR enterography of small bowel, MR cholangiopancreatography [MRCP] of the biliary and pancreatic system). MRI yields better soft contrast resolution than CT and does not expose individuals to ionizing radiation, but due to longer image time is motion artifact-prone and thus less suited to resolving gastrointestinal detail. MRI has disadvantages in that it may require sedation in those with claustrophobia and in young individuals who may be unable to hold still and follow directions. MRI also cannot be performed in those with ferrous magnetic implants or non-removable foreign bodies.[8]

Asymptomatic Adrenal Cortical Lesions (AB-16.1)

AB.AC.0016.1.A
v1.0.2026

Overall Considerations

- The following recommendations are for asymptomatic individuals:
  - For symptomatic individuals, see: **Symptomatic Adrenal Cortical Lesions (AB-16.2)**.
  - US is not a prerequisite study for advanced imaging in the evaluation of any adrenal abnormality.
- Abdominal pain may be present in large or rapidly expanding adrenal tumors due to mass effect or hemorrhage.
  - If the source of abdominal pain is suspected to be an incidental adrenal mass and initial imaging was indeterminate, immediate reimaging with a dedicated adrenal protocol study (see 3 imaging modalities below) is reasonable irrespective of the size of the mass.
  - See: **Abdominal Pain (AB-2)** in the Abdomen Imaging Guidelines for imaging recommendations if abdominal pain is unrelated to the adrenal mass.
- The three imaging modalities that can be used for definitive benign characterization of an adrenal mass are:
  - CT Abdomen without contrast (CPT® 74150)
  - CT Abdomen without and with contrast (CPT® 74170)
  - CS-MRI (chemical shift MRI, CPT® 74181)
- The following list represents definitively benign characteristics of the adrenal gland. This list applies wherever "benign characteristics" are mentioned in the table below:
  - ≤10 HFU on CT
  - ≥60% absolute washout or ≥40% relative washout on CT abdomen without and with contrast with calculated washout (adrenal protocol CT, CPT® 74170)
    - An important exception to the washout rule: Non-adenomatous adrenal masses that may show elevated washout on adrenal protocol CT but are not benign include:
      - adrenal metastasis from hypervascular tumors (e.g. RCC and HCC)
      - pheochromocytoma
      - adrenocortical carcinoma
      - clinical suspicion should be used in these cases to guide further investigation

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Decreased signal on Chemical Shift MRI (CS-MRI, CPT® 74181)
  - Cyst (if imaging was completed with and without contrast and "no enhancement"- defined as <10HFU change between unenhanced and enhanced/contrasted CT)
  - Adrenal myelolipoma (macroscopic fat)
- If definitively benign diagnosis cannot be made during follow up imaging using dedicated CT adrenal protocol (If <60% absolute washout or <40% relative washout) or lack of signal drop out on MRI chemical shift:
  - Additional imaging is medically necessary at 6-12 months from initial follow up, OR
  - Consider resection for possible primary adrenocortical carcinoma after biochemical evaluation and exclusion of pheochromocytoma.
    - For individuals who are poor surgical candidates, if ordered by or in consultation with an endocrinologist, endocrine surgeon, or urologist:
      - Imaging as requested
- CT Abdomen without and with contrast (CPT® 74170) may be medically necessary in place of any below recommended CT Abdomen without contrast for the following:
  - Facility protocol is to cease imaging if adrenal mass is found to have HFU<10 on initial non-contrasted images
- MRI Abdomen without contrast (CPT® 74181) is medically necessary in place of CT for the following:
  - Clips that cause artifacts when using CT
  - Allergy to CT contrast
  - Individuals in whom radiation exposure should be limited (children, pregnant individuals, individuals with known germline mutations, and individuals with recent excessive radiation exposure)
- CS MRI may not detect the intracellular lipid in an adrenal mass if HFU is 30 HU or more on CT without contrast. CS MRI is less effective than CT without and with contrast with calculated washout for adenomas with unenhanced attenuation of more than 20 HU
- Below imaging can be applied to bilateral adrenal masses, with each lesion addressed separately.

Mass Characteristics and Appropriate Imaging

Mass Details	Imaging Study
• Asymptomatic AND • Incidentally found on US, CT, or MRI of area OTHER than the abdomen or if seen only on US of the abdomen AND • Any size AND • No history of cancer	• CT Abdomen without contrast (CPT® 74150)
• Asymptomatic AND • Incidentally found on CT Chest without contrast, entirely imaged, and fully characterized as indeterminate by HFU score AND • >2 cm AND • No history of cancer	• CT Abdomen without and with contrast (CPT® 74170) in lieu of above recommended CT Abdomen without contrast
• Asymptomatic AND • Incidentally found on CT or MRI of the Abdomen or Abdomen and Pelvis AND • <1 cm in short axis AND • No history of cancer	• No further imaging is medically necessary ◦ It is uncertain as to whether subcentimeter nodularity or adrenal thickening qualifies as an adrenal mass on radiology reports
• Asymptomatic AND • Incidentally found on CT or MRI of the Abdomen or Abdomen and Pelvis AND • No prior imaging for comparison AND • Diagnostic with benign imaging characteristics AND • ≥1 cm AND • No history of cancer	• No further imaging is medically necessary, regardless of size ◦ The risk of malignancy in a mass with diagnostically benign findings on imaging is extremely low

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Mass Details	Imaging Study
• Asymptomatic AND • 1 cm to 2 cm AND • Incidentally detected and indeterminate on any CT or MRI Abdomen or Abdomen and Pelvis AND • No prior imaging for comparison AND • No history of cancer	• Reimaging is medically necessary at 12 months from the initial indeterminate study, as follows*: ◦ CT Abdomen without and with contrast (CPT® 74170 - adrenal protocol), CT Abdomen without contrast (CPT® 74150), or CS-MRI (chemical shift MRI, CPT® 74181) ▪ No further imaging is medically necessary after initial 12 month study if ANY of the following: - Definitively benign characteristics - Stable in size (change <8mm) over >1 year (likely benign adenoma) *NOTE: These instructions are regarding indeterminate lesions without prior studies to compare, in asymptomatic individuals. If prior imaging exists for comparison and radiology report shows stability over 1 year or if the imaging study already shows definitively benign characteristics, no further imaging is medically necessary

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Mass Details	Imaging Study
• Asymptomatic AND • >2 cm to <4 cm AND • Incidentally detected and indeterminate on any CT or MRI Abdomen or Abdomen and Pelvis AND • No prior imaging for comparison AND • No history of cancer	• Reimaging is medically necessary immediately after initial indeterminate study, as follows*: ◦ CT Abdomen without and with contrast (CPT® 74170 - adrenal protocol), or CS-MRI (chemical shift MRI, CPT® 74181) ▪ Further follow-up imaging is medically necessary at 6 and 12 months ▪ No further imaging is medically necessary if the initial study or follow up study has definitively benign characteristics or if follow up study shows stability in size (change <8mm) over >1 year (as likely benign adenoma) *NOTE: These instructions are regarding indeterminate lesions without prior studies to compare, in asymptomatic individuals . If prior imaging exists for comparison and radiology report shows stability over 1 year or if the imaging study already shows definitively benign characteristics no further imaging is medically necessary.
• Asymptomatic AND • ≥4 cm AND • Incidentally detected and indeterminate on any CT or MRI Abdomen or Abdomen and Pelvis AND • No prior imaging for comparison AND • No history of cancer	• Reimaging is medically necessary immediately after initial indeterminate study, as follows: ◦ CT Abdomen without and with contrast (CPT® 74170) or chemical shift MRI (CPT® 74181) • Consider resection for possible primary adrenocortical carcinoma ◦ See: **Adrenocortical Carcinoma (ONC-15.13)** in the Oncology Imaging Guidelines

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Mass Details	Imaging Study
• History of cancer with a likelihood or propensity to metastasize to the adrenal gland or abdomen • Incidentally detected and indeterminate on any CT or MRI Abdomen or Abdomen and Pelvis	• See: **Adrenal Gland Metastases (ONC-31.4)** in the Oncology Imaging Guidelines
• Known adrenal mass with benign characteristics, but newly symptomatic or new hormonal excess	• Repeat imaging per **Adrenal Hormone Excess/Symptomatic Adrenal Lesions (AB-16.2)**

Background and Supporting Information

Benign Adenoma Imaging Characteristics		
	Findings consistent with Adenoma:	Indeterminate for Adenoma:
CT Abdomen without contrast	≤10 Hounsfield Units	>10 Hounsfield Units
CT Abdomen WWO with calculated washout	≥60% absolute washout or ≥40% relative washout	<60% absolute washout <40% relative washout
Chemical Shift MRI	Signal drop out	Lack of signal drop out

- Endocrine guidelines recommend biochemical evaluation in all incidental adrenal lesions (with the exception of myelolipomas and cysts). However laboratory results are NOT required for imaging in an asymptomatic individual.
- Most benign adenomas, which account for up to 75% of adrenal incidentalomas, are lipid rich and thus easily characterized because they measure 10HFU or less on CT without contrast. CT Abdomen without and with contrast with calculated washout and chemical shift MRI help identify lipid poor adenomas, which are the next most common group. Masses which remain indeterminate include pheochromocytomas (up to 7%) and primary adrenal cancers or metastases to the adrenal glands (approximately 4%).
- Adrenal masses are often found incidentally on CT scans performed WITH contrast to evaluate abdominal symptoms. While CT scans performed with contrast only may report the HFU of an adrenal mass, most benign adenomas are labeled "indeterminate" originally because non-contrasted HFU and HFU after washout cannot be measured or calculated.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- An "Adrenal Protocol CT" measures pre-contrast HFU of an adrenal mass as well as the HFU during "wash out" of contrast medium after 60 to 90 seconds [early] and 10 to 15 minutes [delayed]. Benign adenomas show more rapid and efficient contrast washout as compared to malignant adrenal masses.
- When an adrenal mass shows avid enhancement on CT scan (>110 – 120 HU), a pheochromocytoma should be considered.
- In addition to the imaging features in the grid which are considered "diagnostic" of a benign adrenal mass, other radiographic characteristics "suggestive" of a benignity include: smooth/round shape, homogeneous content, lack of calcification/ hemorrhage/necrosis, growth rate <1cm/year, lack of FDG avidity on PET, and <4cm.
- Radiographic characteristics "suggestive" of malignancy include: irregular margins/ shape, heterogeneous content, presence of calcification/hemorrhage/necrosis, growth rate >1cm/year, presence of FDG avidity on PET, and >4-6cm.
- Malignancies most likely to metastasize to the adrenal glands include lung cancer, gastrointestinal cancer, melanoma, and renal-cell carcinoma.

Evidence Discussion

- CT scan of the abdomen is the recommended initial study to evaluate adrenal gland nodules. A CT scan may expose patients to radiation; however, it takes less time to perform and is less costly than an MRI. Additionally, CT scans are superior to MRI when evaluating lesions with higher density, particularly when using an adrenal CT protocol for washout measurements.[8]
- 75% of adrenal incidentalomas are benign, nonfunctioning adenomas. They are lipid-rich, with low density, exhibit Hounsfield Units (HU) of 10 or less, and have other benign characteristic appearances that make them easily identifiable on an unenhanced CT of the abdomen. The sensitivity and specificity for adenoma characterization are 71% and 98%, respectively, when using unenhanced CT scan for lesions having a density of 10 or less HU.[8]
- Unenhanced CT scans of lesions with a density greater than 30 HU had a 66.6% chance of remaining indeterminate, even after evaluation with chemical shift MRI.[8]
- A chemical shift MRI (CS-MRI) of the abdomen is also useful for characterizing adrenal gland masses with lower density. It is an alternative for follow-up studies when there is a contraindication to CT or contrast or during pregnancy. However, it should be cautioned that MRI may not detect intracellular lipid when the adrenal mass has a HU > 30. MRI is also less sensitive in evaluation of masses with higher HU over 20 compared to CT scans that calculate contrast wash out times. [8]
- Adrenal protocol CT, with its high sensitivity (98%) and specificity (92%), should be the study of choice to differentiate between adenomas and non-adenomas when an adrenal mass remains indeterminate.[8]

Adrenal Hormone Excess/Symptomatic Adrenal Lesions (AB-16.2)

AB.AC.0016.2.A
v1.0.2026

Overall Considerations

- Prior to advanced imaging, adrenal hormone excess must be clinically suspected and then biochemically confirmed via testing listed in the table below.
- The following imaging recommendations can also be followed in asymptomatic individuals with an adrenal incidentaloma who are found to have abnormalities at initial hormonal evaluation.
- For severe hormone elevation or rapidly progressing symptoms for which adrenocortical carcinoma is suspected, see: **Adrenocortical Carcinoma (ONC-15.13)** in the Oncology Imaging Guidelines.

Proprietary Information of UnitedHealthcare.

Condition	Signs/Symptoms (not required to be documented for imaging)	Laboratory requirements PRIOR to initial adrenal imaging	Indicated Imaging
• Confirmed adrenal hormone excess AND • Requested for surgical planning AND • Requested by or in consultation with an endocrinologist, endocrine surgeon, or urologist	NA	NA	• Repeat imaging as requested

Background and Supporting Information

- Surgery is the management of choice for individuals with virilizing adrenal tumors, feminizing adrenal tumors, pheochromocytoma/PGL, and suspected adrenocortical carcinoma due to an increased risk of malignancy and/or comorbidity. Adrenal masses that secrete excess cortisol (adrenal Cushing's syndrome) or aldosterone (primary hyperaldosteronism/Conn's syndrome) are rarely malignant; however, surgery is also definitive management.

Suspected cortisol excess (adrenal Cushing's syndrome)

- Low or suppressed ACTH levels (<10 pg/mL) are consistent with an adrenal source.
- DHEAS levels are also low in adrenal Cushing's syndrome.
- The diagnosis of Cushing's syndrome can be delayed for years due to the insidious nature of clinical presentation and the complexity of diagnostic testing.

Suspected adrenal hyperandrogenism/virilizing adrenal tumor

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Testosterone is produced by both the ovary (primary source) and adrenal gland while DHEA and DHEAS are produced almost exclusively by the adrenal gland.
- The magnitude of the androgen level is of poor predictive value for tumors, although a very high testosterone (adult-male range) or DHEAS level (>700 µg/dL) is suggestive.

Suspected feminizing adrenal tumor

- Adrenal tumors, mainly carcinomas (extremely rare, 0.5–2.0 per million), can secrete both estrogens and high amounts of adrenal androgens, which aromatize to estrogens. In this case, gynecomastia is usually of recent onset, progresses rapidly and testicular atrophy can also be seen.
- Common causes of excessive endogenous estrogens should be excluded prior to adrenal imaging. These include increased secretion from testis (Leydig cell or Sertoli cell tumors, stimulation of normal Leydig cells by LH or hCG) and increased aromatization of androgens to estrogens (aging, obesity, alcoholic cirrhosis, hyperthyroidism, drugs, hCG-secreting tumors, aromatase excess syndrome).

Suspected primary aldosteronism (Conn's syndrome)

- A positive screen for primary aldosteronism is an aldosterone level >15-20ng/dL in the setting of suppressed renin* (plasma renin activity <0.6-1.0ng/mL/hour or plasma renin concentration <5-8.2 mU/L) and spontaneous hypokalemia (K<3.5mEq/L).
- The most common dynamic confirmatory tests include the oral sodium suppression test, the seated intravenous saline suppression test, the fludrocortisone suppression test, and the captopril challenge test, and results that indicate a "positive" result are unique to the each test. For example, if oral sodium loading is used, a 24-hour urine aldosterone excretion of more than 12 mcg in the setting of 24-hour urine sodium excretion of more than 200 mEq is diagnostic of primary aldosteronism (and values of more than 10 mcg/24 hours are strongly suggestive).
- Primary hyperaldosteronism may be managed medically with mineralocorticoid receptor antagonists (spironolactone and eplerenone) in cases of bilateral adrenal disease or poor surgical candidacy. If there has been no recent adrenal imaging, reimaging can be considered in cases of diagnostic uncertainty or poor response to medical therapy.

Suspected pheochromocytoma/paraganglioma

- A pheochromocytoma (85% of chromaffin tumors) arises from the chromaffin cells in the adrenal medulla and commonly produces one or more of the following catecholamines: epinephrine, norepinephrine and dopamine.
- A paraganglioma (15-20% of chromaffin tumors) arises from the extra-adrenal chromaffin cells of the sympathetic paravertebral ganglia of the thorax, abdomen, and pelvis (catecholamine producing) or the parasympathetic ganglia along the glossopharyngeal and vagal nerves in the neck and base of skull (not catecholamine producing).

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Cases of pheochromocytoma/paraganglioma can be sporadic but one-third are hereditary and due to germ-line mutations that may increase malignant potential

Suspected adrenocortical carcinoma

- Adrenocortical carcinoma may be suspected radiographically or clinically. Approximately 60% of individuals present with evidence of adrenal steroid hormone excess, with or without virilization. Hormonally inactive ACCs typically produce symptoms related to tumor burden, including abdominal pain, back pain, early satiety, and weight loss.
- See: **Adrenocortical Carcinoma (ONC-15.13)**

Evidence Discussion

- Advanced imaging is medically necessary when there is biochemical confirmation of adrenal hormone excess.[2,7,10,13]
- CT of the abdomen is the initial imaging study of choice to identify adrenal adenomas when adrenal hormone excess is confirmed. CT scans are readily available and can identify if adrenal lesions are present and can show characteristics of the lesions that help to distinguish benign lesions from indeterminate lesions.[2,7,10,13]
- MRI with chemical shift can further help characterize lesions that are indeterminate on CT scan.[2,7,10,13]
- Including the pelvis in CT scan imaging is medically necessary when evaluating for pheochromocytomas or paragangliomas as these tumors can appear in both the abdominal and pelvis areas and also indicated for staging purposes when adrenal carcinoma is suspected.[2,7,10,13]

Adrenal Insufficiency (AB-16.3)

AB.AC.0016.3.A

v1.0.2026

- CT Abdomen (contrast as requested) is medically necessary if the cause of primary adrenal insufficiency is unclear.
  - MRI Abdomen (contrast as requested) is medically necessary if CT is contraindicated.
- Imaging is NOT medically necessary if clinical presentation and labs are consistent with ANY of the following:
  - Primary autoimmune destruction of the adrenal cortex (Addison's disease)
  - Congenital adrenal hyperplasia
  - Adrenoleukodystrophy

Background and Supporting Information

- Imaging can detect infiltrative disease, adrenal hemorrhage, infections, and malignant tumors which may be the cause of adrenal dysfunction.

Evidence Discussion

A CT scan of the abdomen is medically necessary to evaluate the cause of primary adrenal insufficiency when it is unclear. [1-4]

- If screening tests for autoimmune or genetic causes of primary adrenal insufficiency are positive, then imaging is not medically necessary.
- Other causes of primary adrenal insufficiency include adrenal hemorrhage, infiltrative diseases, infections such as tuberculosis, and tumors. All of these can be identified by a CT scan of the abdomen.
- The CT scan is usually readily available, relatively quick to process, and therefore preferred over MRI as the initial study unless contraindicated.
- It can accurately identify the size, location, and appearance of adrenal tumors, as well as the presence of local or vascular invasion, lymph node involvement, and distant metastases in the majority of individuals.
- The CT scan can also accurately identify hemorrhage of the adrenal gland.
- While an abdominal ultrasound is less expensive, it does not provide the precise anatomic definition seen on a CT scan, making the CT scan the preferred study.

Adrenal Nuclear Imaging (AB-16.4)

AB.AC.0016.4.A
v1.0.2026

Nuclear medicine imaging can assist in the evaluation of adrenal masses not adequately characterized by CT or MRI.

- Evaluation of SUSPECTED pheochromocytoma or paraganglioma:
  - MIBG (Any ONE of the following codes can be considered medically necessary: CPT® 78801, CPT® 78802, or CPT® 78804).
    - Any ONE of the following codes may also be considered medically necessary, individual or in combination with CPT® 78801, 78802, 78804: SPECT studies (CPT® 78803 or CPT® 78831), or hybrid SPECT/CT studies (CPT® 78830 or CPT® 78832).
  - Octreotide scans can be considered medically necessary in place of MIBG scans (with the same CPT codes) as requested in rare clinical circumstances including head and neck paragangliomas.
- For PET/CT indications and for cases of KNOWN pheochromocytoma or paraganglioma, see: **Adrenal Tumors (ONC-15.10-15.12)** in the Oncology Imaging Guidelines.
- Evaluation of SUSPECTED neuroblastoma, ganglioneuroblastoma, or ganglioneuromas:
  - MIBG (Any ONE of the following codes can be considered medically necessary: CPT® 78801, CPT® 78802, or CPT® 78804).
    - Any ONE of the following codes may also be considered medically necessary, individual or in combination with CPT® 78801, 78802, 78804: SPECT studies (CPT® 78803 or CPT® 78831), or hybrid SPECT/CT studies (CPT® 78830 or CPT® 78832).
- For KNOWN neuroblastoma, ganglioneuroblastoma, or ganglioneuroma, see **Neuroblastoma (PEDONC-6)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
- Adrenal Nuclear Imaging of the cortex and/or medulla (single site, planar imaging of the adrenal gland only) (CPT® 78075) includes the adrenal scintigraphy scans for 131I-iodocholesterol (NP-59) as well as MIBG (Iodine i-123 iobenguane and Iodine i-131 iobenguane sulfate) scans.
  - 131I-iodocholesterol (NP-59) scans for adrenal cortex imaging can be useful in cases of suspected hyperaldosteronism and adrenal Cushing's, however NP-59 is not readily available for use in the United States.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - MIBG (Iodine i-123 iobenguane and Iodine i-131 iobenguane sulfate) scans for adrenal medulla imaging can be helpful in cases of known pheochromocytoma or neuroblastoma.
    - CPT® 78075 is insufficient for the initial evaluation of a suspected pheochromocytoma, paraganglioma or neuroblastoma as this study does not evaluate extra-adrenal sites of disease, but can be considered in rare circumstances.
    - SPECT and SPECT/CT codes as listed above for MIBG can be added to CPT® 78075 as requested.
- History of multiple endocrine neoplasia syndromes: See **Multiple Endocrine Neoplasias (MEN) (PEDONC-2.8)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
- History of neurofibromatosis: there is insufficient evidence to support routine imaging of adult individuals with Neurofibromatosis in asymptomatic individuals. See: **Adrenal Hormone Excess/Symptomatic Adrenal Lesions (AB-16.2)** if there is concern for pheochromocytoma. Labs would be required before imaging as stated in guideline.
- History of von Hippel-Lindau disease: See **Von Hippel-Lindau Syndrome (VHL) (PEDONC-2.10)** in the Pediatric and Special Populations Oncology Imaging Guidelines.

Evidence Discussion

- Nuclear medicine studies provide functional imaging that helps to further characterize adrenal masses not adequately detailed on CT or MRI.[1-5]
- A meta-analysis found I-123 MIBG sensitivity of 96% in individuals with non-metastatic pheochromocytoma or paraganglioma and 79% in individuals with metastatic pheochromocytoma or paraganglioma.[2]
- Studies have shown excellent lesion-based sensitivity in detecting pheochromocytoma and paraganglioma, often more than 92%, when using ^{68}Ga-DOTATATE (somatostatin analog-SSA) PET/CT.[2]
- A meta-analysis comparing the sensitivity of ^{18}F-FDG and 68Ga-DOTA-SSA found that the sensitivity of ^{68}Ga-DOTA-SSA (95%) was superior to that of ^{18}F-FDG (85%) in detecting pheochromocytoma and paraganglioma.[2]
- Nuclear medicine studies are very useful in head and neck paragangliomas (HNPGL) that prove to be difficult to detect on standard CT or MRI. The sensitivity of ^{68}Ga-DOTATATE was 100% for HNPGL, with identification of additional lesions not visualized with other modalities.[2]
- MIBG or SSA nuclear scans are also very helpful in identifying neuroblastoma, ganglioneuroblastoma, or ganglioneuromas, often associated with Von Hippel-Lindau Syndrome.[1-5]

Bowel Obstruction (AB-20.1)

AB.BO.0020.1.A
v1.0.2026

- Suspected bowel obstruction:
  - CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary
  - Pediatric individuals:
    - MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197) is medically necessary in lieu of CT, if requested.
  - Pregnant individuals:
    - MRI Abdomen and Pelvis without contrast (CPT® 74181 and CPT® 72195) is medically necessary
  - If the etiology or level of suspected intermittent or low-grade small bowel obstruction remains undetermined and additional imaging is needed after CT Abdomen and Pelvis ONE of the following is medically necessary:
    - CT Enteroclysis (CPT® 74176 or CPT® 74177) OR
    - CT Enterography (CPT® 74177) OR
    - MR Enteroclysis (CPT® 74183 and CPT® 72197) OR
    - MR Enterography (CPT® 74183 and CPT® 72197)
- CT Enterography (CPT® 74177) is medically necessary if there is a suspected small bowel tumor as a cause of the small bowel obstruction (including a history of no prior abdominal or pelvic surgery, no known hernia and/or concomitant obscure GI bleeding):
- When Crohn's Disease is the suspected cause of small bowel obstruction:
  - See: Suspected **IBD (Crohn's Disease or Ulcerative Colitis) (AB-23.1)** and **Known IBD (AB-23.2)**
- For small bowel obstruction in individuals with a history of bariatric surgery, see: **Bariatric Surgery Post-Operative Complications (AB-9.1)**

Background and Supporting Information

- Complete or high-grade obstruction can be defined as no fluid or gas passing beyond the site of obstruction. In incomplete or partial obstruction (low-grade), some fluid or gas passes beyond the point of obstruction. A plain film is not required prior to advanced imaging for suspicion of either high- or low- grade obstruction.

Evidence Discussion

In individuals suspected of having small or large bowel obstruction, the best imaging modality is CT of the abdomen and pelvis. Such imaging plays a crucial role in both diagnosis and management. Computed tomography (CT) is more useful than plain

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

radiographs especially in identifying the severity, location, etiology, inflammation, and complications of bowel obstructions including ischemia, necrosis, and perforation. Magnetic resonance imaging (MRI) can be a useful alternative to CT imaging in special populations for whom radiation exposure needs to be limited, but the higher prevalence of motion artifact may make images more difficult to interpret.[1]

Gastroparesis and Dumping Syndrome (AB-20.2)

AB.BO.0020.2.A
v1.0.2026

Gastroparesis

- Gastric Emptying Study (CPT® 78264) is medically necessary for the suspicion of delayed gastric emptying and ONE of the following:
  - Nausea, or vomiting of old food ingested several hours earlier
  - Bloating
  - Early satiety, or postprandial fullness
  - Recurrent aspiration
  - Unexplained poor glucose control in diabetes
  - Gastroesophageal reflux refractory to medical management
  - Non-ulcer dyspepsia
  - Retained gastric contents on endoscopy
- For the evaluation of suspected abnormalities in both total and regional times for small bowel transit
  - Gastric emptying study with small bowel transit (CPT® 78265) is medically necessary
- For the evaluation of suspected abnormalities in both total and regional times for colon transit
  - Gastric emptying study with small bowel and colon transit (CPT® 78266) is medically necessary

Dumping Syndrome

- Gastric Emptying Study (CPT® 78264) to evaluate signs or symptoms of dumping syndrome is not medically necessary.

Note: For both solid-phase and liquid-phase gastric emptying studies
- If performed on the same day by any protocol, CPT® 78264 should not be reported with two units, only one unit.
- If a solid-phase study is performed, and then on a later date a liquid-phase study is performed, one unit of CPT® 78264 should be reported for each date of service.

Evidence Discussion

Gastric emptying scintigraphy uses a radiolabeled solid meal to measure the rate of gastric emptying. This is the conventionally best accepted method to measure gastric

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

emptying. It is performed two to four hours after ingestion of a radiolabeled meal. Performing the test for the longer duration is proposed to increase the accuracy of testing. Gastric emptying with small bowel or colonic transit time can provide further information regarding intestinal and colonic transit time. Gastric emptying scintigraphy has limited value in the evaluation of dumping syndrome, but remains the preferred method for diagnosis of gastroparesis.[3,4,6]

Dumping syndrome is a common complication of gastric and bariatric surgery in which changes in anatomy and innervation promote a rapid emptying of gastric contents into the small bowel. This triggers a series of physiologic responses. "Early dumping," occurs within the first hour after a meal and is characterized by abdominal pain, bloating, gassiness, nausea, vomiting, and diarrhea as well as vasomotor symptoms such as flushing, sweatiness, tachycardia, and hypotension. "Late dumping," symptoms occur between 1 and 3 hours after meals and are usually related to hypoglycemia (e.g. weakness, confusion, syncope).[24]

Dumping syndrome is usually a clinical diagnosis and the recommended diagnostic testing is an oral glucose tolerance test.[24]

Evidence-based guidelines have recently concluded that gastric emptying tests have low sensitivity and specificity for dumping syndrome, and that a gastric emptying test showing a rapid emptying rate would not be used to confirm a diagnosis of dumping syndrome. Rapid emptying can occur in other conditions, and it has been demonstrated that the initial rapid emptying in dumping may produce symptoms such as nausea, which they delays gastric emptying in dumping may produce symptoms such as nausea, which delays gastric emptying, such that the results of a gastric emptying study are in the normal range. Because of these limitation, recent guidelines have concluded that, "gastric emptying testing seems to be of low utility in diagnosing dumping syndrome."[18]

Nausea and Vomiting as the Primary Symptom (AB-20.3)

AB.BO.0020.3.A
v1.0.2026

- The presence of any red flag findings per **General Guidelines (AB-1.0)** precludes adjudication based on any other criteria.
- Nausea and vomiting as the primary symptom
  - An initial assessment should be performed prior to imaging requests. Diagnostic testing for nausea and vomiting should be targeted at finding the etiology suggested by a thorough history and physical examination. In the absence of more complicated or serious disease, if the cause is not obvious or suggestive from the history and physical, laboratory data including a CBC, chemistry profile, and, in a reproductive-age individual, pregnancy testing, should be performed prior to advanced radiographic imaging. Imaging is based on the findings of the initial evaluation as follows:
    - CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary for ANY of the following:
      - If the initial assessment does not suggest a specific cause
      - If the evaluation proves unproductive
    - Symptoms suggesting mucosal disease (e.g. GERD, suspicion of ulcer disease):
      - EGD prior to advanced imaging
    - If nausea and vomiting remains unexplained despite workup and CT Abdomen and Pelvis is negative:
      - Gastric emptying study (CPT® 78264)
    - Symptoms suggesting an intracranial etiology (vertigo/nystagmus, associated headache, or neurogenic vomiting suggested by a positional nature and/or associated with other neurologic signs and symptoms):
      - See: **Headache (HD-11)** , **Dizziness, Vertigo and Syncope (HD-23)** , or other Head Imaging Guidelines depending on the predominant neurologic presentation
      - See: **General Guidelines – Other Imaging Situations (HD-1.7)** in the Head Imaging Guidelines for persistent, unexplained nausea and vomiting, when GI evaluation is negative.
    - Nausea and vomiting associated with RUQ pain, dyspeptic symptoms or epigastric pain, see: **Right Upper Quadrant and Epigastric Pain (AB-2.3)**

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Evidence Discussion

Nausea and vomiting are common symptoms encountered in medicine. Prior to imaging studies, an evaluation including a detailed history including duration, frequency, and severity should be performed. Diagnostic testing for nausea and vomiting should focus on finding the etiology of the symptoms. In addition to a detailed history and physical examination, laboratory work up and pregnancy testing may reveal the etiology of symptoms. The purpose of the initial assessment is to define whether the symptom complex suggests a central (neurologic), endocrine (e.g. pregnancy, thyroid disorder), iatrogenic (chemotherapy/medication-induced), obstructive (e.g., low-grade small bowel obstruction), or a mucosal (gastritis, peptic ulcer disease) etiology. If mucosal disease causing vomiting is suspected, upper endoscopy should be performed prior to advanced imaging. If gallbladder disease is suspected, right upper quadrant ultrasound should be performed. If neurologic symptoms are present, advanced brain imaging may be indicated depending on symptoms and presentation. If the initial evaluation of nausea and vomiting does not reveal a specific cause, advanced imaging may be pursued. CT abdomen and pelvis with contrast provides valuable information regarding abdominal and pelvic anatomy such as obstruction or inflammation and may be used to evaluate nausea and vomiting when clinically appropriate.[7,10,11,12]

Superior Mesenteric Artery (SMA) Syndrome (AB-20.4)

AB.BO.0020.4.A

v1.0.2026

- CTA Abdomen (CPT® 74175) or MRA Abdomen (CPT® 74185) are medically necessary for clinical suspicion of SMA syndrome and ANY of the following:
  - Recent significant weight loss which leads to a loss of retroperitoneal fat
  - Presence of a severe debilitating illness such as malignancy, malabsorption syndromes, AIDS, high-level trauma, and extensive burns
  - History of corrective spine surgery for scoliosis
  - Anorexia Nervosa
  - Abdominal surgery
  - Congenital short ligament of Treitz
  - Radiologic findings or history suggestive of duodenal obstruction
  - Failure to diagnose persistent nausea and/or vomiting despite the workup outlined in **Nausea and Vomiting as the Primary Symptom (AB-20.3)**

Background and Supporting Information

- SMA syndrome is a rare cause of duodenal obstruction in which there is a decrease in the aortomesenteric angle with resulting compression of the duodenum by the SMA.
- The typical clinical scenario includes an episode of weight loss followed by chronic food intolerance with nausea and vomiting, further weight loss, and epigastric pain, and can be relieved by lying prone or in the left lateral decubitus position.
- The diagnosis can be suspected with barium studies demonstrating delayed passage of contrast beyond the duodenum, dilatation of the first and second portions of the duodenum, anti-peristaltic flow of barium proximal to the obstruction, and relief of obstruction when placed in the prone, knee-chest, or left lateral position, or with an upper endoscopy revealing pulsatile extrinsic compression of the duodenum, or plain films suggesting duodenal obstruction.

Evidence Discussion

The gold standard test for suspicion of SMA syndrome is a CTA of the abdomen or an MRA of the abdomen, which confirms the diagnosis and provides a measurement of the angle between the SMA and the abdominal aorta. All other investigative modalities may suggest an obstruction at the third portion of the duodenum but are not diagnostic.[21-23]

Bloating, Gas, and Distention (AB-20.5)

AB.BO.0020.5.A
v1.0.2026

- The presence of any red flag findings per **General Guidelines (AB-1.0)** precludes adjudication based on any other criteria.
- For bloating as the primary symptom, present for at least 3 months, see: **Irritable Bowel Syndrome (AB-21.4)**
- For documented suspicion of bowel obstruction (e.g., individuals with prior abdominal surgery, previous history of SBO, known adhesions, history of Crohn's Disease, etc.) see: **Bowel Obstruction (AB-20.1)**.
- If associated with constipation, see: **Constipation (AB-21.3)**
- If associated with dyspeptic symptoms, see: **Right Upper Quadrant and Epigastric Pain (AB-2.3)**
- CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary if ANY of the following present:
  - History of malignancy with a likelihood or propensity to metastasize to abdomen
  - Fever (≥101 degrees Fahrenheit)
  - Elevated WBC >10,000, or above the upper limit of normal for the particular lab reporting the result
  - Low WBC (absolute neutrophil count <1000)
  - Palpable mass of clinical concern and/or without benign features
  - GI bleeding, overt or occult, not obviously hemorrhoidal
  - Abdominal tenderness documented as moderate or severe
  - Peritoneal signs, such as guarding or rebound tenderness
  - Suspected complication of bariatric surgery
  - Notation by the ordering provider that the patient has a "surgical abdomen"
  - Age >60 years with unintentional weight loss of ≥10 lbs. or ≥5% of body weight over 6 months or less, without an identifiable reason

Background and Supporting Information

Bloating and distension are among the most common gastrointestinal complaints, and appears in 96% of individuals with IBS, and 20-30% of the general population. Bloating is the subjective perception of increased abdominal pressure. Distension is the objective finding of increased abdominal girth.

The following approaches were offered by the American Gastroenterological Association (AGA)[20] as Best Practice Advice in evaluation and management of belching, abdominal bloating, and distension:

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Clinical history and physical examination findings and impedance pH monitoring can help to differentiate between gastric and supra-gastric belching.
- Rome IV criteria (see also: **Irritable Bowel Syndrome [AB-21.4]**) should be used to diagnose primary abdominal bloating and distention.
- Carbohydrate enzyme deficiencies may be ruled out with dietary restriction and/or breath testing. In a small subset of at-risk patients, small bowel aspiration or biopsy may be warranted.
- Serologic testing may rule out celiac disease in individuals with bloating and, if serologies are positive, a small bowel biopsy should be done to confirm the diagnosis.
- Abdominal imaging and upper endoscopy should be restricted to individualss with alarm features, recent worsening symptoms, or an abnormal physical examination.
- Gastric emptying studies should not be ordered routinely for bloating and distention, but may be considered if nausea and vomiting are present. See also: **Gastroparesis and Dumping Syndrome (AB-20.2)**
- Whole gut motility and radiopaque transit studies should be restricted to individuals with refractory lower GI symptoms and suspected neuromyopathic conditions.
- When abdominal bloating and distention may be related to constipation or difficult evacuation, anorectal physiology testing is suggested to rule out a pelvic floor disorder. See also: **Constipation (AB-21.3)**

Evidence Discussion

Determining when symptoms of bloating, gas, and distention require imaging is done by risk stratification using demographics factors such as patient age as well as concomitant signs and symptoms.

- Computer tomography (CT) of the abdomen offers excellent 3-dimensional resolution of the gut and its surrounding structures, especially when performed with use of oral and/or intravenous (IV) contrast agents. CT imaging captures all of the abdominal organs and the surrounding cavity and mesentery. It is central to the evaluation of this condition because it can accurately diagnose the presence and location of obstruction, malignancy, vascular insufficiency, or infection, which are important pathologic diagnoses to identify or exclude in the subset of high-risk individuals. CT scan requires a significant dose of ionizing radiation but is ideally suited to imaging lesions within the gut because the speed of image acquisition reduces the potential for motion artifact. Typically performed with IV contrast in individuals with normal kidney function, there is the added risk of allergic reaction to contrast; however the contrast enhances the ability to evaluate for both infectious and vascular conditions.[8,9,19]

Acute and Persistent Diarrhea (Up to 30 Days) (AB-21.1)

AB.DC.0021.1.A

v1.0.2026

- The presence of any red flag findings per **General Guidelines (AB-1.0)** precludes adjudication based on any other criteria.
- Routine advanced imaging is not medically necessary for uncomplicated diarrhea (up to 30 days in duration).
- Prior to advanced imaging, individuals with travel and/or dysenteric (including bloody) diarrhea should undergo biological assessment and/or antimicrobial treatment.
- CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary if:
  - Suspected ischemia (See: **Mesenteric Ischemia (AB-6.1)** and **Colonic Ischemia (AB-6.2)**) OR
  - Older (>50) individuals with significant abdominal pain OR
  - Previous gastric bypass OR
  - Immunocompromised OR
  - Obstruction, toxic megacolon, or perforation suspected

Evidence Discussion

Acute or persistent diarrhea is a common complaint that most often results from self-limited infectious or digestive causes, and for this reason, imaging is generally not medically necessary. Four weeks or more is used as the time frame to describe when diarrhea is no longer considered acute because "intestinal infections, the most common cause of acute diarrhea, typically resolve in 1 week or 4 weeks at the most".[14] However, in a subset of individuals and in the setting of clinical suspicion, imaging is medically necessary to exclude vascular insufficiency, perforation, obstruction and severe metabolic derangement. Determining the situations in which imaging is medically necessary is based on provider concern for such conditions in addition to demographic factors such as age and prior medical and surgical history. When imaging is medically necessary, CT scan with contrast is the modality of choice.[2,11]

- Computer tomography (CT) of the abdomen offers excellent 3-dimensional resolution of the gut and its surrounding structures, especially when performed with use of oral and/or intravenous (IV) contrast agents. CT imaging captures all of the abdominal organs and the surrounding cavity and mesentery. It is central to the evaluation of this condition because it can accurately diagnose the presence and location of obstruction, malignancy, vascular insufficiency, toxic megacolon, and perforation in the subset of high-risk individuals. CT scan requires a significant dose of ionizing radiation but is ideally suited to imaging lesions within the gut because the speed of

image acquisition reduces the potential for motion artifact. Typically performed with IV contrast in individuals with normal kidney function, there is the added risk of allergic reaction to contrast, however the contrast enhances the ability to evaluate for both infectious and vascular conditions.[2,11]

Chronic Diarrhea (More than 30 Days) (AB-21.2)

AB.DC.0021.2.A
v1.0.2026

- Prior to advanced imaging, basic lab work should include routine CBC, chemistries, as well as stool tests for pathogens.
- CT Abdomen with contrast (CPT® 74160), CT Abdomen and Pelvis with contrast (CPT® 74177), CT Enterography (CPT® 74177), or MR Enterography (CPT® 74183 or CPT® 74183 and CPT® 72197), is considered medically necessary if ALL of the following have been performed:
  - Colonoscopy has been performed and is nondiagnostic or suggestive of inflammatory bowel disease
  - Fecal calprotectin or fecal lactoferrin
  - Testing for giardia antigen or PCR for giardia
  - Testing for celiac disease with serum IgA tissue transglutaminase (tTG)
- See: **Suspected IBD (Crohn's Disease or Ulcerative Colitis) (AB-23.1)** for concerns regarding inflammatory bowel disease.

Evidence Discussion

Chronic diarrhea is defined as "a condition in which diarrhea that persists or recurs for four weeks or more causing various problems in daily life." Four weeks or more is used as the time frame because "intestinal infections, the most common cause of acute diarrhea, typically resolve in 1 week or 4 weeks at the most".[14]

The initial evaluation of chronic diarrhea (more than 30 days) involves non-imaging modalities (blood tests, stool tests, and colonoscopy), to evaluate for celiac disease, giardia, and inflammatory bowel disease. If these evaluations are non-diagnostic, imaging can be considered to identify more unusual causes of chronic diarrhea such as obstruction, malignancy, biliary causes, and small bowel disorders such as small bowel Crohn's disease.[6,11]

- Computer tomography (CT) of the abdomen offers excellent 3-dimensional resolution of the gut and its surrounding structures, especially when performed with use of oral and/or intravenous (IV) contrast agents. CT imaging captures parts or the whole of the abdomen, or can be directed to interrogate with specialized techniques a specific organ. Depending on clinical suspicion, for this condition, CT of the abdomen, CT of the abdomen and pelvis or specialized CT enterography of the small bowel may be employed. CT scan requires a significant dose of ionizing radiation, but is ideally

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

suited to imaging lesions within the gut because the speed of image acquisition reduces the potential for motion artifact.[6,11]

- Magnetic resonance imaging (MRI) uses a magnetic field to capture excellent 3-dimensional resolution. As with CT scans, the technique is often performed with IV contrast agents, and can with specialized techniques be directed either at whole or parts of the abdomen or at specific abdominal structures. For this condition MR enterography delivers high resolution images of small bowel mucosa to evaluate for the subtle inflammatory changes such as those seen in small bowel Crohn's disease. MRI yields better soft contrast resolution than CT and does not expose individuals to ionizing radiation, but due to longer image time is motion artifact-prone and thus less suited to resolving gastrointestinal detail. In addition, and especially in youths, MRI may require sedation.[6,11]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Constipation (AB-21.3)

AB.DC.0021.3.U
v1.0.2026

- The presence of any red flag findings per **General Guidelines (AB-1.0)** precludes adjudication based on any other criteria.
- CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary if:
  - Concern for obstruction
- MRI (MRI Pelvis without contrast CPT® 72195) for Defecography is considered investigational/experimental by UHC.

Background and Supporting Information

- The work-up and treatment of constipation usually proceeds with a history and physical followed by empiric medication or dietary trials.
  - In general, a colonoscopy is performed prior to advanced imaging in an individual presenting with chronic constipation if the alarm symptoms of blood in the stool, anemia, or weight loss are present.

Evidence Discussion

Clinical presentation and results of minimally invasive testing determine the situations in which constipation requires imaging.

- Computer tomography (CT) of the abdomen offers excellent 3-dimensional resolution of the gut and its surrounding structures, especially when performed with use of oral and/or intravenous (IV) contrast agents. CT imaging captures all of the abdominal organs and the surrounding cavity and mesentery. It is central to the evaluation of individuals with constipation alongside red flag symptoms that suggest infection or malignancy. CT scan requires a significant dose of ionizing radiation but is ideally suited to imaging lesions within the gut because the speed of image acquisition reduces the potential for motion artifact. Typically performed with IV contrast in individuals with normal kidney function, there is the added risk of allergic reaction to contrast; however, the contrast enhances the ability to evaluate for both infectious and malignant conditions.[3,4,5]

Irritable Bowel Syndrome (AB-21.4)

AB.DC.0021.4.A
v1.0.2026

- The presence of any red flag findings per **General Guidelines (AB-1.0)** precludes adjudication based on any other criteria.
- Advanced imaging in the absence of alarm symptoms has a very low yield, but can be considered medically necessary in the following circumstances:
  - CT Abdomen with contrast (CPT® 74160) or CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary in the following circumstances:
    - Presence of ANY of the following alarm symptoms:
      - Weight loss
      - Frequent nocturnal awakenings due to gastrointestinal symptoms
      - Fever
      - Blood in the stool or iron deficiency anemia (See: **GI Bleeding (AB-22)** for appropriateness of imaging in this circumstance)
      - New onset and progressive symptoms
      - Onset of symptoms after age 50
      - Family history of colon cancer or inflammatory bowel disease
      - Findings of an abdominal mass
      - Presence of lymphadenopathy
    - After ALL of the following studies have been performed:
      - Fecal calprotectin ≥50ug/g or fecal lactoferrin ≥4.0ug/g or CRP >0.5 in individuals with diarrhea-predominance
      - Testing for giardia antigen or PCR for giardia
      - Celiac testing should also be performed in individuals with diarrhea-predominance IBS, and if positive see: **Celiac Disease (AB-24.1)** for imaging guidance.
        - See also: Background and Supporting Information in IBD **(Crohn's Disease or Ulcerative Colitis) (AB-23.1)**

Background and Supporting Information

- Irritable bowel syndrome is characterized by abdominal pain associated with altered bowel habits, abdominal distention, and bloating. It is important to understand that IBS is a positive diagnosis, not a diagnosis of exclusion. ACG guidelines (2021) strongly suggest that IBS be assessed with a “positive diagnostic strategy as compared to a diagnostic strategy of exclusion”. Subtypes include IBS-C (constipation-predominant), IBS-D (diarrhea-predominant), IBS-M (mixed), and unclassified IBS. Rome IV Criteria for the diagnosis of irritable bowel syndrome are:

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Recurrent abdominal pain, on average ≥1 d/wk in the past 3 months, related to ≥2 of the following:
  - Defecation
  - Change in stool frequency
  - Change in stool appearance (form)

Evidence Discussion

Risk stratification (using demographics factors such as individual age, family history, timing of symptoms, concomitant symptoms, and physical exam findings) determines the situations in which imaging is medically necessary for irritable bowel syndrome. In a subset of individuals, imaging is medically necessary to exclude inflammatory conditions such as Crohn's disease and malignant conditions such as bowel cancer.[7,8,9]

- Computer tomography (CT) of the abdomen offers excellent 3-dimensional resolution of the gut and its surrounding structures, especially when performed with use of oral and/or intravenous (IV) contrast agents. CT imaging captures all of the abdominal organs and the surrounding cavity and mesentery. It is central to the evaluation of this condition because it can accurately identify both the presence and location of inflammatory conditions and malignant conditions in the appropriately identified subset of high-risk individuals. CT scan requires a significant dose of ionizing radiation but is ideally suited to imaging lesions within the gut because the speed of image acquisition reduces the potential for motion artifact. Typically performed with IV contrast in individuals with normal kidney function, there is the added risk of allergic reaction to contrast; however, the contrast enhances the ability to evaluate for both inflammatory and malignant conditions.[7,8,9]

GI Bleeding (AB-22.1)

AB.GI.0022.1.A

v1.0.2026

- CTA Abdomen (CPT® 74175), CTA Abdomen and Pelvis (CPT® 74174), or CT Abdomen and Pelvis with contrast (CPT® 74177) are medically necessary for the initial evaluation of ANY of the following:
  - If therapeutic angiography is being considered
  - If colonoscopy cannot be performed in an individual with active lower GI bleeding
  - If endoscopy cannot be performed in an individual with active upper GI bleeding
  - If surgery is being considered for treatment of GI bleeding
  - GI bleeding and moderate to severe abdominal pain and/or tenderness
  - GI bleeding and hemodynamic instability
  - If there is concern for an aorto-enteric fistula (known or suspected aortic aneurysm, history of any type of aortic aneurysm repair)
- If there is brisk active bleeding AND endoscopy does not reveal a source
  - Gastrointestinal Bleeding Scintigraphy (CPT® 78278) is medically necessary
- Iron Deficiency Anemia:
  - If the bleeding is of suspected gastrointestinal origin:
    - Upper endoscopy and colonoscopy should be performed, unless contraindicated
    - Small bowel video capsule endoscopy is medically necessary, if endoscopies are negative
    - If small bowel video capsule endoscopy is negative OR for further evaluation of abnormal video capsule findings ONE of the following is medically necessary:
      - CT Abdomen and Pelvis with contrast (CPT® 74177)
      - CT Enterography (CPT® 74177)
      - MR Entergraphy (CPT® 74183 or CPT® 74183 and CPT® 72197) is medically necessary if there is a contraindication to CT Enterography.
- If the bleeding is determined to be non-gastrointestinal, refer to the appropriate condition-based guideline.

Evidence Discussion

In individuals suspected of having GI bleeding, after initial endoscopic evaluation if feasible, the best imaging modality is CT or CTA of the abdomen and pelvis. Such imaging plays a crucial role in both diagnosis and management. Computed tomographic angiography (CTA) is more expedient and accurate at localizing the site of bleeding as compared to gastrointestinal bleeding scintigraphy (tagged RBC scintigraphy) which can be a useful alternative in the setting of active GI bleeding, especially if it is slow or

intermittent. CTA is the exam of choice for potential causes of catastrophic bleeding such as aortoenteric fistula, transmural bowel injuries, and mesenteric hemorrhage.[24]

Small Bowel Bleeding Suspected (AB-22.2)

AB.GI.0022.2.A

v1.0.2026

- If the small bowel is the suspected source of bleeding, and if endoscopic studies (upper endoscopy, colonoscopy and if available video capsule endoscopy) are unrevealing:
  - CT Enterography (CPT® 74177) is medically necessary
  - MR Enterography (CPT® 74183 or CPT® 74183 and CPT® 72197) is medically necessary, if there is a contraindication to CT Enterography
- Meckel's scan (CPT® 78290) is medically necessary if bleeding is suspected from a Meckel's diverticulum.

Evidence Discussion

The goal of identifying the source of GI tract bleeding is to identify lesion, location, and ability to perform therapeutic intervention. Bleeding from the small bowel is uncommon, accounting for approximately 5–10% of all individuals presenting with gastrointestinal (GI) bleeding. The initial diagnostic modality of choice is endoscopy or colonoscopy to help identify lesions and execute appropriate interventions.[6,19, 20,21,22,23]

Video capsule endoscopy (VCE) is considered a first-line modality for small bowel investigation. Its main advantages are that it is noninvasive and allows examination of the entire length of the small bowel in 70-90% individuals with diagnostic yield of 38–83% in individuals with suspected small bowel bleeding. The main utility of this test lies in its high positive (94–97%) and negative predictive value (83–100%) in the evaluation of GI bleeding. Findings on VCE leading to endoscopic or surgical intervention or a change in medical management have been reported in 37–87% of individuals.[6,19, 20,21,22,23]

Providers occasionally request a CT or MR Enterography prior to the administration of a VCE, in order to assess whether there is pathology that might impede passage of the capsule and cause retention. This is not supported as a routine procedure prior to VCE. It should be noted that a patency capsule is available, and that this may identify individuals at higher risk of retention. However, guidance from the consensus group of the American College of Gastroenterology recommends that in individuals with obstructive symptomatology, imaging (MR Enterography or CT Enterography) should be performed prior to VCE. This group would also include high risk individuals with a known history of Crohn's Disease, known history of strictures or other obstruction, history of previous pelvic or abdominal radiation, or suspected tumor.[6,19, 20,21,22,23]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Computed tomographic enterography is indicated in individuals with suspected obstruction before VCE or after negative VCE examinations, women who are pregnant, and individuals who are unable to swallow the VCE capsule.[6,19, 20,21,22,23]

Cross-sectional imaging techniques optimized for imaging the small bowel are advantageous due to ability to see all bowel loops without superimposition and the visualization of extra-luminal structures. Enterography can be performed with either CT or MR. CT is more widely used in the setting of GI bleeding because of the superior temporal and spatial resolution compared with MR and is more widely available. CT can detect vascular and inflammatory abnormalities, which may be missed on VCE. Because of the small number of studies regarding MR enterography, this exam is not routinely recommended in lieu of CT enterography, but can be considered medically necessary in individuals aged <40 years because of lower radiation exposure.[6,19,20,21,22,23]

Click Here to Return to the Main TOC

Suspected IBD (Crohn's Disease or Ulcerative Colitis) (AB-23.1)

AB.IB.0023.1.A
v1.0.2026

- Suspected Crohn's Disease or Ulcerative Colitis:
  - CT Abdomen and Pelvis with contrast (CPT® 74177) OR CT Enterography (CPT® 74177) OR MR Enterography (CPT® 74183 or CPT® 74183 and CPT® 72197) is medically necessary for ANY of the following:
    - History of malignancy with a likelihood or propensity to metastasize to abdomen
    - Fever (≥101 degrees Fahrenheit)
    - Elevated WBC >10,000, or above the upper limit of normal for the particular lab reporting the result
    - Palpable mass of clinical concern and/or without benign features
    - GI bleeding, overt or occult, not obviously hemorrhoidal
    - Abdominal tenderness documented as moderate or severe
    - Peritoneal signs, such as guarding or rebound tenderness
    - Suspected complication of bariatric surgery
    - Notation by the ordering provider that the patient has a "surgical abdomen"
    - Age >60 years with unintentional weight loss of ≥10 lbs. or ≥5% of body weight over 6 months or less, without an identifiable reason
  - Chronic diarrhea without the above signs or symptoms, see: **Diarrhea, Constipation, and Irritable Bowel (AB-21)**
  - CT Enterography (CPT® 74177) OR MR Enterography (CPT® 74183 or CPT® 74183 and CPT® 72197) is medically necessary for the evaluation of chronic abdominal pain with diarrhea in the absence of red flag criteria (as noted in **General Guidelines AB-1.0**) when there is documented concern for inflammatory bowel disease and if ANY of the following:
    - There is a positive family history of inflammatory bowel disease, **OR**
    - There are endoscopy or colonoscopy findings suggestive of inflammatory bowel disease, **OR**
    - Elevated inflammatory markers (fecal lactoferrin ≥4.0 ug/g, CRP >0.5 mg/dL, or fecal calprotectin ≥50 ug/g), **OR**
    - Diagnosis is still in doubt after colonoscopy and evaluation of inflammatory markers, and Crohn's disease is suspected
  - CT Abdomen and Pelvis with or without contrast (CPT® 74177 or CPT® 74176) can be performed prior to endoscopy if requested by or in consultation with the provider who will be performing the endoscopy.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Note:

Serologic markers and genetic markers are currently under investigation with regards to their value in diagnosing inflammatory bowel disease, and are sometimes used as a screening test for IBD in which other examinations are negative. At the current time they are not considered suitable as a screening test for inflammatory bowel disease in individuals with GI symptoms, and the routine use of serologic or genetic markers for the diagnosis of IBD is not indicated. Thus, an isolated positive marker result in an individual without any other findings to suggest IBD, especially in the presence of negative inflammatory markers and endoscopic examinations, is not, in and of itself, an indication for advanced imaging.

- Serologic markers include anti-glycan antibodies, such as ASCA, ACCA, ALCA, AMCA, Anti-L, Anti-C, Anti-OmpC, Anti-Is, Anti-Cbir, pANCA, PAB, GAB

Background and Supporting Information

Studies have demonstrated the negative predictive value of a low fecal calprotectin and CRP with regards to inflammatory bowel disease. Chey, et al. in a meta-analysis demonstrated that a fecal calprotectin <40mcg/g or a CRP ≤0.5 mg/dl effectively excludes inflammatory bowel disease in individuals with IBS. Katsinelos, et al. reviewed wireless capsule endoscopy results in individuals with abdominal pain and diarrhea. The diagnostic yield of capsule endoscopy in individuals with abdominal pain and diarrhea with positive inflammatory markers was 90.1%, and 0% in indviduals with abdominal pain and diarrhea with negative inflammatory markers. This led the Canadian Association of Gastroenterology to recommend against the use of capsule endoscopy in individuals with chronic abdominal pain or diarrhea as their only symptoms and no evidence of biomarkers associated with Crohn's Disease, stating "CE (capsule endoscopy) is not warranted in most indviduals who present with chronic abdominal pain in the absence of positive tests for inflammatory markers or abnormal findings on endoscopy or imaging".

Evidence Discussion

In individuals with suspected inflammatory bowel disease, cross-sectional imaging can be performed after initial endoscopy is suggestive of inflammatory changes or if abnormal inflammatory markers concerning for IBD, or positive family history of IBD. Cross-sectional imaging methods such as computed tomography and magnetic resonance imaging are complementary to endoscopy, which allows diagnosis of disease when endoscopy is negative and diagnosis is still in doubt.[1,2,3,4,16]

Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Known IBD (AB-23.2)

AB.IB.0023.2.A

v1.0.2026

- CT Abdomen and Pelvis with contrast (CPT® 74177), CT Enterography (CPT® 74177), or MR Enterography (CPT® 74183 or CPT® 74181 and CPT® 72197 or CPT® 72195) is medically necessary for known Crohn's Disease or Ulcerative Colitis and ANY of the following:
  - To determine change in treatment
  - Monitoring response to therapy
  - Suspected complications including abscess, perforation, fistula, or obstruction

Evidence Discussion

Cross-sectional imaging methods such as computed tomography and magnetic resonance imaging are utilized to evaluate IBD disease activity, extra-enteric complication and response to therapy with a great impact on patient management. Magnetic resonance imaging (MRI) either with or without contrast or diffusion weighted has now emerged as suitable radiation-free alternative to CT imaging, with comparable diagnostic accuracy. [1,2,3,4,20,21,22,23]

MRE should be used preferentially in young individuals and in individuals in whom it is likely that serial exams will need to be performed, because of the absence of any radiation exposure.[1,2,3,4,20,21,22,23]

Click Here to Return to the Main TOC

Perirectal/Perianal Crohn's Disease (AB-23.3)

AB.IB.0023.3.A
v1.0.2026

- Perirectal/Perianal Fistula:
  - MRI Pelvis without and with contrast (CPT® 72197)
  - Endoscopic ultrasound is preferential to CT in this setting.
  - CT Pelvis with contrast (CPT® 72193) is an inferior study in this setting, and should be used when MRI or Endoscopic ultrasound cannot be performed.
- Perirectal/Perianal Abscess:
  - MRI Pelvis without and with contrast (CPT® 72197)
  - CT Pelvis with contrast (CPT® 72193) is inferior but can be considered medically necessary as an alternative if desired.

This section is applicable to individuals with Crohn's Disease. See: **Fistula in Ano (PV-21.1)** and **Perirectal Abscess (PV-21.2)** in the Pelvis Imaging Guidelines for non-Crohn's related perirectal and/or perianal fistulae.

Evidence Discussion

Cross-sectional imaging methods such as magnetic resonance imaging and computed tomography are utilized to evaluate Crohn's related complications like perirectal and/or perianal fistulae or abscess. CT is useful in evaluating abscesses and inflammation; however, due to its limited resolution, defining fistulas may be difficult. MRI, which has better resolution, along with endoscopic ultrasound, are highly accurate in defining perianal and perirectal fistulas and are the preferred modalities for diagnosing fistulas secondary to Crohn's disease.[4]

Primary Sclerosing Cholangitis (PSC) (AB-23.4)

AB.IB.0023.4.A
v1.0.2026

- Primary Sclerosing Cholangitis (PSC):
  - MRCP is medically necessary to assess for PSC in those:
    - with IBD and any elevated liver study (including alkaline phosphatase, GGTP, bilirubin, AST, or ALT)
    - without IBD, but with persistent cholestatic liver tests. (See: **Abnormal Liver Chemistries (AB-30)**)
  - Ultrasound (CPT® 76700 or 76705) or MRI/MRCP is medically necessary as surveillance for cholangiocarcinoma in individuals with PSC every 6 months.

Background and Supporting Information

Primary sclerosing cholangitis (PSC) is a chronic liver and biliary tract disease that can result in stricturing and fibrosis of the intra- and extra- hepatic biliary ducts, as well as end-stage liver disease. It is most often associated with inflammatory bowel disease. Biliary obstruction can occur anywhere along the biliary tree, resulting in cholangitis, and there is a high risk of the development of cholangiocarcinoma, which must be strongly considered in individuals with PSC and a dominant stricture, as well as an increased risk of gallbladder polyps and other malignancies. As such, imaging plays an important role in the diagnosis and follow-up of PSC.

See: **Chronic Liver Disease, Cirrhosis and Screening for HCC (AB-26.1)** Background and Supporting Information PSC (Primary Sclerosing Cholangitis) vs PBC (Primary Biliary Cholangitis)

Evidence Discussion

The diagnosis of primary sclerosing cholangitis can be confirmed via magnetic resonance cholangiography (MRCP) when suspected, in individuals with IBD or in individuals with persistent cholestasis, in the absence of known IBD. Surveillance for cholangiocarcinoma in individuals with PSC is important because it allows for disease progression as well as monitoring for the development of cancer. Studies show that there is survival benefit to routine surveillance with MRCP, although ultimately the reason for this survival benefit is not clear.[24] MRI has been shown to have better diagnostic performance than ultrasound in detecting early stage cholangiocarcinoma (a potential risk for individuals with PSC) and earlier detection is associated with more favorable prognostic features.[25] Data is variable on the optimal timeframe for

Celiac Disease (AB-24.1)

AB.CD.0024.1.A

v1.0.2026

- CT Abdomen and Pelvis with contrast (CPT® 74177), CT Enteroclysis (CPT® 74176 or CPT® 74177), or CT Enterography (CPT® 74177), or MR Enterography (CPT® 74183, or CPT® 74183 and CPT® 72197) is medically necessary for:
  - one-time study after initial, confirmed diagnosis of celiac disease OR
  - confirmed celiac disease and new or continued symptoms (e.g., bloating, diarrhea, abdominal pain, weight loss, distention, evidence of malabsorption, anemia) despite adherence to 6 months of a gluten free diet

Background and Supporting Information

- Celiac is an autoimmune disease in which the villi of the small intestine are damaged from eating gluten (found in wheat, barley, and rye).
- Complications of celiac disease include ulcerative jejunitis, lymphoma, and small intestinal adenocarcinoma.
- Diagnosis is made by blood testing:
  - Anti-tissue transglutaminase antibody [anti-tTG], anti-endomysium antibody (EMA), total IgA count, CBC to detect anemia, ESR, C-reactive protein, complete metabolic panel, vitamin D, E, B12 levels.
- Endoscopy with biopsy of the small bowel is performed to confirm the diagnosis of celiac disease if anti-tTG and/or EMA tests are positive.
- Capsule endoscopy may be used to confirm diagnosis of celiac disease in individuals with positive serology and negative biopsy, or when there is contraindication to biopsy or EGD.

Evidence Discussion

Serologic studies with antibody testing and upper endoscopy and small bowel biopsies are usually performed to confirm the diagnosis of celiac disease.[1] The findings on standard barium examination are often not specific. Abdominal pain, bloating, diarrhea, and evidence of malabsorption are frequent symptoms of celiac disease, as well as indications for CT imaging. The use of standard CT abdominal imaging, as well as CT Enteroclysis and CT Enterography, allow for the noninvasive assessment of the small bowel to evaluate the extent of disease and identify complications of the disease (including ulcerative jejunoileitis, lymphoma, and small bowel tumors). Early diagnosis of these disorders allows specific treatment to be initiated to prevent increased morbidity and mortality. Added advantages of CT imaging for the diagnosis of celiac disease are simultaneous visualization of the small and large bowel, as well as visualization of mesenteric lymph nodes to determine the presence of mesenteric adenopathy.[5,7]

CTC (AB-25.1)

AB.CT.0025.1.A
v1.0.2026

Note:

A screening CTC (CPT® 74263) can ONLY be used for an individual who is a candidate for average risk screening as defined below. It cannot be used for any other indication. If the request for a CTC is for any other reason than average risk screening, please refer to diagnostic CTC indications. A diagnostic CTC would be the appropriate code, if approvable, for any other reason than average risk screening. This would include surveillance for a history of colon polyps, the evaluation of a change in bowel habits, abdominal pain, bleeding, etc. Please refer to the definition below of an average-risk individual, as well as the circumstances for which a diagnostic CTC is appropriate.

- Screening CTC (CPT® 74263) for colorectal cancer is NOT medically necessary if:
  - FIT-DNA (multi-targeted stool DNA test) within the last 3 years, OR
  - colonoscopy within the last 10 years
- Screening CTC (CPT® 74263) is medically necessary every 5 years for colorectal cancer for:
  - Average-risk individuals ages 45 to 75
    - Average risk is defined as:
      - no previously diagnosed colorectal cancer, or colonic adenomas, or inflammatory bowel disease involving the colon
  - Individuals between 76 to 85 if there is no history of a previously negative colonoscopy or CTC, or, if in the opinion of the provider, the benefits of screening outweigh the risks.
  - Individuals with a SINGLE first-degree relative diagnosed at age >60 years with colorectal cancer or an advanced adenoma can be screened with CTC beginning at age 40.
    - If there are 2 or more first degree relatives at any age with CRC or an advanced adenoma, or a first degree relative <60, the individual should be screened via colonoscopy, not CTC.
- Diagnostic CTC without contrast (CPT® 74261) is medically necessary for:
  - Failed conventional colonoscopy due to a known colonic lesion, structural abnormality, or technical difficulty, and/or
  - Conventional colonoscopy is medically contraindicated. Contraindications may include:
    - Coagulopathy
    - Intolerance to sedation

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

    - Elderly ≥80 years of age
    - Recent (within the last 60 days) myocardial infarction (MI)
- Diagnostic CTC with contrast (CPT® 74262) is medically necessary if:
    - there is a known obstructing colorectal malignancy so that staging prior to surgery can be performed, if desired.
    - there is a clearly stated indication for IV contrast to evaluate extra-colonic organs. When performed in this setting, a CTC with contrast will substitute for a CT Abdomen and Pelvis such that an additional CT Abdomen and Pelvis would generally not be medically necessary.
- MRI Colonography:
    - Currently, no published society-endorsed guideline with respect to colorectal cancer screening lists MRI Colonography as an alternative screening study. As such, requests for MRI Colonography would be considered investigational at this time. There is no specific CPT assigned for this procedure. It is sometimes requested as an MRI Abdomen and MRI Pelvis.

Background and Supporting Information

CT Colonography is routinely performed without contrast, and IV contrast is not needed in most cases.

Evidence Discussion

When it comes to screening with CT colonography, guidelines differ regarding the best approach for colorectal cancer (CRC) screening in asymptomatic, average-risk individuals. Generally, CTC is not advised for screening in individuals at an increased risk for CRC. This includes those with a history of adenomas or CRC, inflammatory bowel disease, or familial CRC syndromes.[1,2,3,4]

CTC is comparable to colonoscopy in terms of sensitivity and specificity, takes only about 15 minutes, is non-invasive, and often requires no sedation. However, the cathartic agents recommended for CTC are the same as those for conventional colonoscopy. Additionally, CTC imaging is associated with considerable radiation exposure and detected polyps cannot be removed during the procedure. Therefore, those with positive findings on their CTC will require a follow-up colonoscopy.[1,2,3,4]

Notably, the American Cancer Society and US Preventive Services Task Force recommend CTC for screening.[3,8,9]

Chronic Liver Disease, Cirrhosis and Screening for HCC (AB-26.1)

AB.CL.0026.1.A
v1.0.2026

HCC Screening and Surveillance

- Ultrasound (CPT® 76700 or CPT® 76705) every 6 months for HCC screening is medically necessary in ANY of the following circumstances:
  - All individuals, regardless of etiology, with cirrhosis or advanced fibrosis (e.g., Fibrosis Score F3 or greater on an elastography study, or results of a lab study such as FIB-4 or a biopsy indicative of severe activity or advanced fibrosis).
  - All individuals with Hepatitis B, regardless of the presence of cirrhosis or advanced fibrosis.
- See: **Hepatic Arteries and Veins (AB-43.1)** for individuals with Chronic Budd-Chiari Syndrome (BCS) and HCC surveillance in Budd-Chiari Syndrome/Hepatic Vein Thrombosis.
- See: **Monitoring After Fontan Procedure (AB-26.4)** for individuals who have undergone the FONTAN procedure.
- See: **General Guidelines (AB-1.0)** for use of medications or treatments which increase risk of HCC.

Evaluation of Liver Nodules

- If liver nodule is identified in the setting of chronic liver disease:
  - Less than 1cm
    - Repeat US in 3 months, then every 3 to 6 months
    - If stable for 2 years, then return to US every 6 months
  - Greater than or equal to 1cm
    - Multiphase CT Liver (either CPT® 74160 or CPT® 74170) or MRI Abdomen (CPT® 74183) should be performed.
      - If negative: Return to routine surveillance via US in 6 months.
      - If Li-RADS NC (non-categorizable): Repeat the same study or an alternative diagnostic imaging ≤3 months. (Note: non-categorizable refers to a technical problem with the study, such as image omission or severe degradation)
      - If Li-RADS 1 (definitely benign): Return to routine surveillance via US in 6 months.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

  - If Li-RADS 2 (probably benign): CT or MRI in 6 months can be approved (US requests are approvable if desired). If unchanged, return to routine surveillance via US.
  - If Li-RADS 3 (intermediate): CT or MRI in 3-6 months, and can be repeated every 6 months 2 more times, for a total of 18 months from the initial finding. If no change by 18 months, return to US surveillance every 6 months.
  - If Li-RADS 4 (probable HCC): Repeat or alternative imaging in ≤3 months. If HCC confirmed: See: **Upper GI Cancers (ONC-14)** in the Oncology Imaging Guidelines.
  - If Li-RADS 5 (HCC confirmed): See: **Upper GI Cancers (ONC-14)** in the Oncology Imaging Guidelines.
  - If Li-RADS M (Malignant, not definitely HCC): Repeat or alternative imaging in ≤3 months, and follow appropriate Oncology guidelines upon diagnosis.

- Exceptions to the above algorithms:
  - Advanced imaging (Multiphase CT Liver (either CPT® 74160 or CPT® 74170) or MRI Abdomen (CPT® 74183) for surveillance may be substituted for US in the following circumstances:
    - Obesity (BMI >35)
    - Marked parenchymal heterogeneity (suggestive of advanced liver fibrosis) noted on US
    - Visualization limitations noted on US which could be technical (such as obscuration by intestinal gas, chest wall deformity, etc.), or those related to structural or parenchymal changes in the liver
  - For individuals on the Liver Transplant list: See: **Liver Transplant, Pre-Transplant (AB-42.1)**
  - For Magnetic Resonance Elastography (MRE) indications, see: **Liver Elastography (AB-45)**
- Alpha-fetoprotein ≥20 ng/mL: Multiphasic CT or MRI Abdomen:
  - Further imaging should follow the above Li-RADS algorithm, depending on the findings of the CT or MRI.
  - If the initial CT or MRI does not reveal a lesion, but the AFP increases on subsequent testing, additional advanced imaging by CT or MRI may be approved.
- Contrast-Enhanced Ultrasound (CEUS)
  - Further studies are needed to assess the value of CEUS in this setting, and it is not medically necessary at this time.

Background and Supporting Information

When performed for liver lesion evaluation, a multiphase CT protocol may include non-contrast imaging as well as arterial, portal venous, and delayed-phase post-contrast imaging. However, these protocols do not always require non-contrast imaging which

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

may not provide additional information in many scenarios. Therefore, a multiphase CT for liver lesion evaluation can be requested as CPT® 74160 (CT Abdomen with contrast) or CPT® 74170 (CT Abdomen without and with contrast).

The presence of liver disease in the absence of advanced fibrosis or cirrhosis, with the exception for those circumstances indicated above, is not an indication for screening. This would include, for example, MASLD (metabolic dysfunction associated steatotic liver disease, formerly known as NAFLD), the presence of which is not an indication for screening in the absence of either advanced fibrosis or cirrhosis

The American Association for the Study of Liver Diseases (AASLD) revised its guidelines with respect to surveillance for HCC in individuals with cirrhosis in 2018. The recommended algorithm now includes either US alone or US with serum AFP every 6 months. It should be noted that “modification of this surveillance strategy based on the etiology of liver diseases or risk stratification models cannot be recommended at this time.”

In addition, the AASLD also issued a subsequent Practice Guidance in 2018 and this document forms the basis of these guidelines. The AASLD has adopted the Li-RADS classification of liver lesions with respect to HCC surveillance imaging for individuals with advanced liver disease, and follow-up imaging protocols are based on this system. In view of this, the Li-RADS classification now informs imaging protocols used in this guideline.

Note: PSC (Primary Sclerosing Cholangitis) vs. PBC (Primary Biliary Cholangitis)

These 2 entities sound similar, and both are cholestatic, but they are different diseases, and as such have different monitoring requirements.

PSC is an idiopathic cholestatic disease characterized by chronic inflammation, progressive fibrosis, and stricturing of the *medium and large-sized* extra-hepatic or intra-hepatic bile ducts. Segmental bile duct dilation proximal to areas of stricturing creates the characteristic beaded appearance on a cholangiogram, such as MRCP. This may progress and eventually lead to cirrhosis as well. It is most commonly associated with inflammatory bowel disease. From a surveillance standpoint, PSC may be complicated by disease-associated malignancies, including cholangiocarcinoma, hepatocellular carcinoma, and pancreatic cancer. Thus, follow-up imaging in this setting is generally via MRCP +/- MRI Abdomen (CPT® 74181 or CPT® 74183) – See: **Primary Sclerosing Cholangitis (PSC) (AB-23.4)**.

PBC is a complex, chronic, and slowly progressive autoimmune liver disease that predominately affects women, and is characterized by cholestatic liver biochemistries as well as the presence of AMA (Anti-Mitochondrial Antibodies), and results in T-lymphocyte-mediated destruction of *small* intrahepatic bile ducts. This may ultimately lead to cirrhosis, and thus an increased risk of hepatocellular carcinoma. Because of this, surveillance via US screening protocols for HCC are followed in PBC.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

It may be necessary, when the diagnosis of PBC is uncertain, for an MRCP to be performed in order to distinguish between PBC and PSC. However, MRI or MRCP is not used for serial monitoring for PBC, once the diagnosis is established. This is in contradistinction to PSC, in which MRCP is used to surveil for cholangiocarcinoma, as discussed above.

Evidence Discussion

Ultrasound has several advantages over advanced imaging techniques such as computed tomography (CT) and magnetic resonance imaging (MRI). Ultrasound requires no ionizing radiation, is readily available, cost-effective, and often allows for same-day scheduling. The reproducibility of results has made it the initial modality of choice for imaging hepatobiliary conditions and screening for hepatocellular carcinoma (HCC) for the past 20 years. Ultrasound also helps to determine the next appropriate advanced imaging study - whether CT, MRI, or magnetic resonance cholangiopancreatography (MRCP) - along with contrast levels.[19,21,24,25]

Disadvantages include image quality degradation due to bowel gas, challenges in acquiring an acoustic window, obesity, and sonographer inexperience.[19,21,24,25]

Although emerging data may support CT and MRI-based liver surveillance, AASLD does not currently recommend their routine use in individuals at risk for HCC. Studies from Asia suggest that both two-phase CT and hepatobiliary contrast-enhanced MRI are more sensitive for early-stage HCC detection compared to US-based surveillance, with sensitivities of 83% and 86% versus 28%–29%, respectively. However, neither CT nor MRI has been validated in Western patient cohorts without chronic viral hepatitis B. Additionally, CT-based surveillance raises concerns about radiation and contrast exposure, especially if conducted semiannually. Similarly, MRI contrast agents present concerns regarding radiology service capacity, patient acceptance, and cost-effectiveness.[19,21,24,25]

Relative to surveillance, AASLD acknowledges the suboptimal performance of CT or MRI in accurately diagnosing HCC in lesions <1cm. AASLD recommends observing individuals with sub-centimeter liver lesions on ultrasound by repeat short-interval surveillance using ultrasound and AFP in 3-6 months. Imaging by multiphase CT or contrast-enhanced MRI is advised for those with new or enlarging solid liver lesions >1 cm and individuals with unequivocally elevated AFP independent of ultrasound results.[19,21,24,25]

Ascites (AB-26.2)

AB.CL.0026.2.A

v1.0.2026

- Abdominal ultrasound (CPT® 76700 or CPT® 76705) and/or Doppler (CPT® 93975) with diagnostic paracentesis required for all initial evaluations of ascites to determine the need for further or advanced imaging.
  - Further advanced imaging is determined by the nature of etiology of the ascites (e.g., portal hypertension secondary to cirrhosis, malignancy such as ovarian or pancreatic, heart failure, etc.).
- Peritoneal-venous shunt patency study (CPT® 78291) is considered medically necessary for evaluation of shunt patency and function in an individual with ascites.

Background and Supporting Information

- Guidance from the American Association for the Study of Liver Diseases (2021) indicates that the initial evaluation of individuals with ascites should include a medical history, physical examination, abdominal US with Doppler, lab studies including CBC, Liver function tests, serum and urine electrolytes and paracentesis with ascitic fluid analysis, which then guides further management. They specifically note that "A diagnostic paracentesis should be performed in all individuals with new-onset ascites that is accessible for sampling".

Evidence Discussion

According to AASLD guidance for ascites management, Doppler ultrasound is the preferred initial radiologic test. Ultrasound is highly sensitive for diagnosing ascites and does not expose individuals to radiation.[15]

Depending on the analysis of the ascitic fluid, further imaging such as CT (to evaluate for malignancy or cirrhosis) or an echocardiogram (for heart failure) may be warranted.[3,12,13]

For individuals with refractory ascites and a LaVeen Shunt, a nuclear peritoneal-venous shunt study is the recommended imaging choice.[3,12,13]

Portal Hypertension (AB-26.3)

AB.CL.0026.3.A
v1.0.2026

- In evaluating the cause of portal hypertension:
  - Abdominal US (CPT® 76700 or CPT® 76705) and/or Duplex Doppler US [CPT® 93975] of the liver and upper abdomen is medically necessary to distinguish ANY of the following:
    - pre-hepatic causes (including portal vein thrombosis, extrinsic compression from a tumor)
    - intrahepatic causes (including cirrhosis)
    - post-hepatic (including hepatic vein thrombosis)
- CT Abdomen with contrast (CPT® 74160) or MRI Abdomen with contrast (CPT® 74183) is medically necessary for ANY of the following indications:
  - Ultrasound is technically limited in assessing hepatic and/or portal vessels
  - Suspicion of portal vein thrombosis, cavernous transformation, or extrinsic impression, but ultrasound was indeterminate
  - Portal hypertension along with secondary signs are present (including splenomegaly or porto-systemic collaterals)
- For TIPS (transjugular intrahepatic portosystemic shunt)
  - See: **Hepatic Arteries and Veins (AB-43.1)**

Background and Supporting Information

- Causes of portal hypertension can be divided into pre-hepatic (e.g., portal vein thrombosis, extrinsic compression from a tumor), intrahepatic (e.g. cirrhosis) and post-hepatic (e.g., hepatic vein thrombosis).
- Most cases of portal hypertension are caused by cirrhosis. Cirrhosis is a histologic diagnosis. The term compensated advanced chronic liver disease (cACLD) encompasses a spectrum of fibrosis and cirrhosis that may be difficult to distinguish on clinical grounds alone since cACLD individuals may manifest with few signs or symptoms.
- When cirrhosis progresses to "decompensated advanced chronic liver disease" (dACLD) individuals may present with ascites, encephalopathy, varices. The most feared complication of portal hypertension is the development of gastro-esophageal varices with hemorrhage
- The gold standard for the assessment of portal hypertension is the Hepatic Venous Pressure Gradient (HPVG [pressure gradient between portal vein and the inferior vena cava]), which is an invasive test. This is the pressure gradient between portal vein and the inferior vena cava. Clinically significant portal hypertension (CSPH) is defined by HPVG of > 10 mm Hg. Measurement of HPVG requires invasive testing.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

There is however a non-invasive test alternative to guide imaging and to risk stratify between CSPH and cACLD. This test combines the Platelet Count with measurement of liver stiffness (LSM), typically from transient elastography (e.g., FibroScan). Risk is best summarized by the "Rule of Five."

- The "Rule of Five," thresholds are as follows:
  - LSM < 15 kPa and platelet count > 150,000/mm³: Low risk of CSPH — endoscopy can be avoided.
  - LSM between 15–25 kPa or platelet count < 150,000/mm³: Intermediate risk — further evaluation or endoscopy may be needed.
  - LSM ≥ 25 kPa: High likelihood of CSPH — endoscopy is recommended.

Evidence Discussion

Initial evaluation of individuals suspected of portal hypertension (PH) should always include a detailed history and physical exam, as well as appropriate lab studies and non-invasive assessment of liver parenchyma by ultrasound. Valuable information is added about alterations in hepatic vascular flow per Doppler ultrasound.[27,28]

In cases of uncertainty, abdominal CT scan or MRI may be warranted. Individual specific factors however should be herein considered such as pregnancy, tolerance to long image acquisition time and confined spaces, high cost, as well as exposure to contrast agents and ionizing. [21,22,23]

Surrogate markers of clinically significant portal hypertension (CSPH) include the presence of gastroesophageal varices or portosystemic collaterals. When such markers are not apparent, clarification may require invasive studies such as liver biopsy or hepatic venous pressure gradient (HVPG) measurement.[27]

However, non-invasive studies have emerged as preferred assessment tools when cACLD is suspected. Transient elastography (TE) correlates liver stiffness (LSM) with the degree of liver fibrosis. Patients with LSM 5-10 kPa do not have cACLD and can be monitored for liver disease progression by serial LSM every 2-3 years.[27,28]

More recent refinement of non-invasive risk assessment of CSPH combines LSM and platelet count. Individuals at low risk of gastro-esophageal varices can be monitored annually. For individuals with higher risk for cACLD or CSPH the "Rule of Five" guides further decision-making.

Monitoring After Fontan Procedure (AB-26.4)

AB.CL.0026.4.A

v1.0.2026

- Abdominal ultrasound (CPT® 76700 or CPT® 76705) and Doppler (CPT® 93975) are medically necessary every 6 months or per institution protocol.
- MR Elastography (CPT® 76391) is medically necessary every 6 months
- If any sized lesions are detected on ultrasound:
  - MRI Abdomen without contrast, or without and with contrast (CPT® 74181 or CPT® 74183) with follow-up timeframes as requested.
- If advanced fibrosis or cirrhosis is detected on any imaging modality:
  - HCC monitoring every 6 months after advanced fibrosis or cirrhosis is detected with MRI Abdomen without contrast, or without and with contrast (CPT® 74181 or CPT® 74183) is medically necessary.
- CT Abdomen and Pelvis with contrast (CPT® 74177), CT Abdomen with contrast (CPT® 74160), or other elastography techniques (i.e., Fibroscan) can be used to assess and monitor individuals with contraindications to MRI (e.g., pacemaker devices, etc.).

Evidence Discussion

Individuals with single-ventricle physiology who have undergone the Fontan Procedure which redirects venous blood flow to the pulmonary circulation invariably develop liver complications, which can include the development of nodules and cirrhosis secondary to the altered vascular anatomy, and thus are at risk for hepatocellular carcinoma. In addition, the congestive hepatopathy associated with the Fontan procedure makes differentiation of focal liver lesions from congestive changes more challenging than other cirrhotic conditions. Thus, most institutions use MRI rather than US for monitoring in the setting of cirrhosis. In addition, the evaluation for HCC is challenging due to the vascular changes associated with the Fontan procedure, because the typical HCC pattern of delayed venous-phase contrast washout may not be appreciated within the background congestive hepatopathy. Thus, biopsy is usually required. Also, distinguishing dysplastic lesions from true HCC based on LiRADS criteria is very challenging as well. There are no current society endorsed guidelines, and institutions may vary in the monitoring of chronic liver disease in this patient population. The above algorithm represents an accepted approach and is consistent with the consensus from the Fontan-Associated Liver Disease proceedings from the American College of Cardiology Shareholders Meeting (2015) as well as the consensus of a multidisciplinary group of American Society of Transplantation members (2020).[2,7,8,15]

MRCP (AB-27.1)

AB.MR.0027.1.A

v1.0.2026

- MRCP (Magnetic Resonance Cholangio Pancreatography) is a non-invasive imaging procedure, which is used to visualize the biliary and pancreatic ductal system. It is used most often in the following circumstances:
  - Suspected gallstone pancreatitis (See: **Pancreatitis (AB-33)**)
  - Suspected biliary pain (See: **Right Upper Quadrant and Epigastric Pain (AB-2.3)**
  - Pancreatic cyst and pseudocyst evaluation (See: **Pancreatic Lesion (AB-31)**, and **Pancreatitis (AB-33)**)
  - Choledochal cyst surveillance (See: **Biliary Disease PEDAB-16.2**)
  - Evaluation of abnormal liver chemistries (See: **Abnormal Liver Chemistries (AB-30.1)**)
  - Evaluation of the pancreas secondary to abdominal trauma with suspected duct injury or pseudocyst
  - Recurrent pancreatitis of unknown etiology (See: **Pancreatitis (AB-33)**)
  - Evaluation and follow-up of Primary Sclerosing Cholangitis (See: **Primary Sclerosing Cholangitis (PSC) (AB-23.4)**)
  - Evaluation of jaundice (See: **Abnormal Liver Chemistries (AB-30.1)**)
  - Evaluation of congenital anomalies of the cystic and hepatic ducts
  - Post-surgical biliary anatomy and complications (See: **Liver Transplant, Post-Transplant Imaging (AB-42.3)**)
  - For further evaluation of ultrasound or CT findings of abnormally dilated biliary duct, dilated pancreatic duct, or enlargement or fullness of the pancreas.
- Code assignment for MRCP
  - In general, there is no specific CPT code to describe MRCP. To report an MRCP, one of the MRI Abdomen codes should be selected, depending on contrast needs (CPT® 74181, CPT® 74182, or CPT® 74183). There is also a level II HCPCS code for MCRP, S8037. Simultaneous billing of any of these codes is redundant and unnecessary.
  - Reporting or billing a *second* MRI code to represent the “MRCP portion” of the study is not supported. When this occurs, it is usually seen as two simultaneous MRI requests, an MRI Abdomen without and with contrast (CPT® 74183) AND an additional MRI Abdomen without contrast (CPT® 74181). This second MRI code, as noted, is not supported. Both the primary MRI Abdomen AND the MRCP portion of the study are covered by the single MRI Abdomen code (CPT® 74183).

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Requests for 3D rendering (either CPT® 76376 or CPT® 76377) are approvable, if requested, in addition to the primary MRI Abdomen code (CPT® 74181, CPT® 74182, or CPT® 74183).

Evidence Discussion

Magnetic Resonance Cholangiopancreatography (MRCP) is the preferred imaging modality for assessing the biliary and pancreatic systems, offering soft tissue contrast resolution without ionizing radiation exposure. Literature highlights MRCP's high sensitivity and specificity in detecting various hepatobiliary pathologies, including choledocholithiasis, cholangitis, pancreatitis and pancreatic neoplasms. Moreover, MRCP provides detailed visualization of the pancreatic duct and biliary tree, facilitating accurate diagnosis and surgical planning. While ERCP is the gold standard for visualization of pancreaticobiliary ducts and provides opportunity for therapeutic intervention, MRCP is a non-invasive method that has gained wide acceptance for diagnostic evaluation.[1,2,4]

Limitations around MRCP include its slower acquisition time with associated higher sensitivity to motion artifact, potential need for sedation, contraindications related to ferrous magnetic implants or foreign bodies, and relatively higher cost compared to alternate options, such as ultrasound or CT. Accessibility could also be an issue, potentially leading to diagnostic delays in some healthcare settings. Safety concerns mainly revolve around gadolinium-based contrast agents, particularly in individuals with compromised renal function.[1,2,4]

Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Gallbladder (AB-28.1)

AB.GP.0028.1.A
v1.0.2026

- Findings on ultrasound or EUS suspicious for malignancy:
  - CT Abdomen with or without and with contrast (CPT® 74160 or CPT® 74170)
- Findings on ultrasound inconclusive for adenomyomatosis:
  - Contrast-Enhanced US (CEUS, CPT® 76978, CPT® 76979)
    - If US and CEUS are inconclusive for adenomyomatosis:
      - MRI Abdomen without and with contrast (CPT® 74183)
- For confirmed gallbladder malignancy:
  - See **Gallbladder and Biliary Tumors - Initial Work-up/Staging (ONC-14.6)** in the Oncology Imaging Guidelines

Gallbladder Polyps

- Individuals at increased risk for gallbladder malignancy (if surgery not chosen):
  - Age >50
  - Primary Sclerosing Cholangitis
  - Indian ethnicity
  - Sessile polyp or gallbladder wall thickening >4mm
- Increased risk for gallbladder malignancy:
  - Polyp <6 mm
    - Ultrasound at 6 months, then yearly for 5 years
  - Polyp 6-9 mm (If cholecystectomy is not chosen)
    - Ultrasound at 6 months, then yearly for 5 years
- No increased risk for gallbladder malignancy:
  - Polyp <6 mm
    - Ultrasound at 1, 3, and 5 years
  - Polyp 6-9 mm
    - Ultrasound at 6 months, and then yearly for 5 years
- Gallbladder polyp ≥10 mm:
  - Surgery recommended. If surgery not performed, follow guidelines for increased risk of gallbladder malignancy as noted above.
- Alternative Imaging:
  - Endoscopic ultrasound (EUS) may provide additional information in the diagnosis of gallbladder polyps. There is insufficient data that advanced imaging (CT or MRI) should be used ahead of conventional ultrasound in the investigation of gallbladder polyps.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Evidence Discussion

Transabdominal ultrasound is the preferred modality for surveillance of polyps, aiming for stability at the 5-year mark as an endpoint. There is insufficient data that advanced imaging (CT or MRI) should be used ahead of conventional ultrasound in the investigation of gallbladder polyps.[1]

Cholecystectomy is recommended for symptomatic individuals, lesions that increase by more than 2 mm in size, and polypoid lesions in individuals who are considered high risk.[8]

There is no role for CT, MRI, or endoscopic ultrasound in the surveillance of polypoid lesions of the gallbladder. However, advanced imaging is useful in evaluation of ultrasound findings that are suspicious for malignancy. CT can help to demonstrate any bile duct dilation as well as assist in staging, planning, and management of any found malignancy.[4]

Ultrasound is also the preferred modality for gallbladder adenomyomatosis. Bonatti, et al. state "the use of high-frequency probes and a precise focal depth adjustment enable correct identification and characterization of GA in the majority of cases" (2017). MRI is reserved only for instances of suspected gallbladder adenomyomatosis when ultrasound techniques are inconclusive.[5]

Liver Lesion Characterization (AB-29.1)

AB.LL.0029.1.A
v1.0.2026

Note:

Advanced imaging approvals in this section refers to MRI Abdomen without and with contrast (CPT® 74183), CT Abdomen with contrast (CPT® 74160), CT Abdomen without and with contrast (CPT® 74170) and Contrast-Enhanced Ultrasound (CPT® 76978-initial lesion, CPT® 76979-additional lesions). In the following section, if only CT Abdomen with contrast (CPT® 74160) is noted as the appropriate study, it is because the American College of Radiology has determined that a prior without contrast study does not provide any added benefit. It should also be noted that a standard "triple-phase CT" liver does not involve a prior without contrast study (See: CT Imaging (AB-1.2))

Indeterminate Liver Lesions

- Indeterminate liver lesion discovered on US:
  - Indeterminate Liver Lesion ≥1cm on initial imaging
    - No suspicion or evidence of extrahepatic malignancy or underlying liver disease:
      - MRI Abdomen without and with contrast (CPT® 74183) or CT Abdomen with contrast (CPT® 74160) or Contrast-Enhanced US (CEUS, CPT® 76978, CPT® 76979)
    - Known history of an extrahepatic malignancy:
      - MRI Abdomen without and with contrast (CPT® 74183) or CT Abdomen with contrast or without and with contrast (CPT® 74160 or CPT® 74170)
    - Known history of chronic liver disease:
      - See: **Chronic Liver Disease, Cirrhosis, and Screening for HCC (AB-26.1)**
  - Indeterminate Liver Lesion <1cm on initial imaging
    - Known underlying chronic liver disease
      - See: **Chronic Liver Disease, Cirrhosis, and Screening for HCC (AB-26.1)**
    - Known history of an extrahepatic malignancy:
      - MRI Abdomen without and with contrast (CPT® 74183) is the preferred study.
      - Contrast-Enhanced US (CPT® 76978, CPT® 76979) is appropriate.
- Indeterminate liver lesion discovered on non-contrast CT or non-contrast MRI
  - Liver lesion on initial imaging
    - No suspicion or evidence of extrahepatic malignancy or underlying liver disease
      - Multiphase CT Abdomen with contrast (CPT® 74160), MRI Abdomen without and with contrast (CPT® 74183), or CEUS (CPT® 76978 and/or CPT® 76979)

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

        - Known history of extrahepatic malignancy:
            - MRI Abdomen without and with contrast (CPT® 74183), CT Abdomen with contrast or without and with contrast (CPT® 74160 or CPT® 74170), or CEUS (CPT® 76978 or CPT® 76979)
        - Known chronic liver disease:
            - See: **Chronic Liver Disease, Cirrhosis, and Screening for HCC (AB-26.1)**
- Additional scenarios and follow-up imaging for an Indeterminate lesion in an individual based on risk factors:
    - Low risk individuals defined as:
        - No known primary malignancy
        - No hepatic dysfunction (abnormal liver tests)
        - No underlying chronic liver disease
        - No history of alcoholism, sclerosing cholangitis, choledochal cysts, hemochromatosis, or anabolic steroid use
    - High risk individuals would have ONE or MORE of the above conditions.
    - Indeterminate lesion <1cm on US, CT, or MRI, **low-risk** individual and no suspicious imaging features noted on the study
        - No further imaging
    - Indeterminate lesion <1cm in **high-risk** individuals on US, CT, or unenhanced MRI not specifically dealt with in the above guidelines:
        - MRI Abdomen without and with contrast (CPT® 74183)
        - If, after MRI, the lesion remains indeterminate or not fully characterized
            - See: **Liver Metastases (ONC-31.2)** or malignancy-specific guidelines in the Oncology Imaging Guidelines.
            - If biopsy cannot be performed, follow-up MRI can be obtained in 3-6 months. Additional imaging in this setting can be considered on an individual basis. This timeframe would also apply if the lesion is indeterminate and an MRI with Eovist is requested for further evaluation in this setting.
    - Most lesions ≥1cm can be categorized by MRI or histology. For lesions which have been categorized, regardless of size, see below.

Focal Liver Lesions

- For the imaging of specific focal liver lesions:
    - Suspected hepatic adenoma:
        - MRI is considered the best technique for characterization. Follow-up imaging can be CT Abdomen (CPT® 74160 or CPT® 74170) or MRI Abdomen (CPT® 74183) every 6 months for 2 years, and then annually, to establish any growth patterns and assess for malignant transformation.
    - Hepatic Hemangioma (if not completely characterized on initial CT without a liver protocol):

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Multiphase CT Abdomen (CPT® 74160 or CPT® 74170) or MRI Abdomen (CPT® 74183)
- Follow-up imaging is medically necessary as follows:
  - In individuals with cirrhosis or chronic hepatitis B, continued imaging with multiphase CT Abdomen (CPT® 74160 or CPT® 74170) or MRI Abdomen (CPT® 74183) every 3-6 months for one year.
    - For continued HCC surveillance after one year, see also: **Chronic Liver Disease, Cirrhosis and Screening for HCC (AB-26.1)**
  - Giant hemangiomas (>4cm) can be followed by limited abdominal US in 6-12 months. If no change in size, no further follow-up is indicated, unless it becomes symptomatic.
  - See below for pre-operative considerations

◦ Focal Nodular Hyperplasia (FNH):
- MRI Abdomen (CPT® 74183) or CT Abdomen (CPT® 74160 or CPT® 74170) to confirm a diagnosis of FNH. The use of Eovist contrast is often diagnostic in differentiating FNH from other lesions seen on MRI or CT.
- Additional follow-up is annual US for 2 to 3 years in women diagnosed with FNH who are continuing to use oral contraceptives. Follow-up with CT (CPT® 74160 or CPT® 74170) or MRI (CPT® 74183) can be done if the lesion is not adequately visualized on US.

◦ Hepatic cysts:
- Asymptomatic, simple cysts do not require additional follow-up.
- For complicated cysts (US shows internal septations, fenestrations, calcifications, irregular walls, as well as the presence of daughter cysts):
  - CT Abdomen (CPT® 74160 or CPT® 74170) or MRI Abdomen (CPT® 74183) can be performed

- **Additional indications for advanced imaging (MRI Abdomen or CT Abdomen)**:
  - If documented that a percutaneous liver biopsy is to be considered if imaging is atypical or inconclusive.
  - Fatty liver (hepatic steatosis) on US with a focal liver lesion.
  - **If there is a technical limitation to US (e.g. marked heterogeneity, or other specifically noted technical limitations of US such as obscuration by intestinal gas, chest wall deformity, etc.)
  - For suspected liver metastases, see: **Liver Metastases (ONC-31.2)** in the Oncology Imaging Guidelines
- Preoperative studies for individuals with large hemangiomas or adenomas considered for resection:
  - MRA Abdomen (CPT® 74185) or CTA Abdomen (CPT® 74175) can be considered
- For Indeterminate Lesions ≥1cm in categories for which defined guidelines do not exist (i.e., underlying chronic liver disease, **Chronic Liver Disease, Cirrhosis,**

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

and Screening for HCC (AB-26.1), underlying malignancy, **Liver Metastases (ONC-31.2)** or the specific malignancy in the Oncology Imaging Guidelines, hepatic adenoma, etc.) a biopsy should be considered when the findings from advanced imaging are inconclusive. In clinical situations when a biopsy cannot be performed (such as a medical contraindication or a liver transplant candidate due to the risk of needle-tract seeding), or is inconclusive, a short-term surveillance MRI can be performed in 3-4 months to monitor lesion stability.

- This can be repeated every 6 months, as necessary in this scenario. This timeframe would also apply if an MRI with Eovist is requested for short-term follow-up of an indeterminate lesion imaged on MRI Abdomen without and with contrast performed with other contrast, such as gadolinium. An exception would be if the differential is between FNH vs. hepatic adenoma or other benign lesions. FNH follow-up is yearly, and hepatic adenoma would require a 6 month follow-up study; if the differential of the lesion is between FNH and hepatic adenoma, then the follow-up study should be 6 months.
- Nuclear Medicine imaging of the Liver (CPT® 78201, CPT® 78202, CPT® 78803, CPT® 78215, CPT® 78216, or CPT® 78830) are rarely performed, but can be considered medically necessary when US, CT, and MRI are unavailable or contraindicated for:
  - evaluation of liver mass, trauma, or suspected focal nodular hyperplasia (FNH)
  - differentiation of hepatic hemangioma from FNH
  - diffuse hepatic disease or elevated liver function tests

Evidence Discussion

For further characterization of a liver lesion seen on other imaging, CT offers high spatial resolution and rapid image acquisition, making it suitable for initial characterization of liver lesions. CT can be highly accurate in establishing whether or not a liver lesion is benign.[1,2] CT Abdomen is generally not the appropriate study in liver lesions < 1 cm with a known history of an extrahepatic malignancy due to the resolution of CT does not allow for definitive characterization of lesions <1cm.

MRI provides superior soft tissue contrast and multi-parametric capabilities, facilitating further tissue characterization when needed (particularly small lesions). Nonetheless, the use of gadolinium-based contrast agents in MRI poses safety concerns, including the risk of nephrogenic systemic fibrosis (NSF) in individuals with impaired renal function. For individuals with a history of malignancy outside the liver, MRI is more accurate at differentiating between benign and malignant lesions. Thus, CT is not recommended over MRI in this scenario.[1,2]

Fatty Liver (Metabolic Associated Steatotic Liver Disease (MASLD), formerly known as NAFLD) (AB-29.2)

AB.LL.0029.2.A

v1.0.2026

- Fatty liver (hepatic steatosis) incidentally discovered on imaging (US/CT/MRI) or suspected:
  - Magnetic Resonance Elastography (MRE) (CPT® 76391) may be medically necessary if criteria are met, see: **Liver Elastography (AB-45)**
  - Magnetic Resonance-Protein Density Fat Fraction (MRI-PDFF, usually requested as CPT® 74181 or 74183), MR Spectroscopy (MR-S, CPT® 76390), and the multiparametric MRI referred to as Liver Multiscan (LMS, Category III CPT® code 0648T or 0649T) for evaluation of fatty liver disease:
    - With regards to the above procedures, their main current utility is in assessing response to therapy in clinical trials. Their role in clinical practice, or with what frequency one would image, has not been defined. In view of this, they are experimental and investigational at this time.
  - HCC Screening for Fatty Liver with cirrhosis or advanced fibrosis:
    - See: **Chronic Liver Disease, Cirrhosis, and Screening for HCC (AB-26.1)**
  - MRI or CT for the further evaluation of incidentally discovered fatty liver on US, in the absence of a specific finding needing further characterization such as a nodule, is generally not medically necessary. See: **Liver Lesion Characterization and Additional Indications for Advanced Imaging (AB-29.1)**. In addition, the finding of fatty liver alone on CT with contrast does not require MRI for confirmation.
  - Requests for imaging studies to screen individuals at high-risk for MASLD (formerly known as NAFLD) (e.g., diabetes or obesity) or for screening family members of individuals with MASLD is not approvable at this time.

Evidence Discussion

Fatty liver is often detected incidentally by ultrasound, CT, or MRI performed for other indications. Fat detected in the liver may have many causes including medications, starvation, excessive alcohol intake, other chronic medical illnesses, and metabolic syndrome. Non-Alcoholic Fatty Liver Disease (NAFLD), now known as Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD), is the most common cause of steatotic (fatty) liver. NALFD (used throughout henceforth) can often lead to serious liver injury (non-alcoholic steatohepatitis: NASH) and complications of cirrhosis. Therefore,

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

monitoring using additional imaging modalities may be medically necessary, in addition to other non-invasive tests.[32]

For those individuals where fatty liver is incidentally discovered on imaging (US/CT/MRI) or in conditions where NAFLD is suspected, Magnetic Resonance Elastography (MRE) may be medically necessary.[32]

Other procedures, such as Magnetic Resonance-Protein Density Fat Fraction, MR Spectroscopy, and the multiparametric MRI referred to as Liver Multiscan may be ordered for evaluation of fatty liver disease but their main current utility is in assessing response to therapy in clinical trials and are considered investigational.[32]

Requests for imaging studies to screen individuals at high-risk for NAFLD (e.g., diabetes or obesity) or for screening family members of individuals with NAFLD is not medically necessary at this time.[3, 32]

Polycystic Liver Disease (AB-29.3)

AB.LL.0029.3.A
v1.0.2026

- Polycystic Liver Disease
  - Defined as >20 cysts, or the presence of cysts occupying one-half the volume of the hepatic parenchyma.
  - Most commonly seen as an extra-renal manifestation of Autosomal Dominant Polycystic Kidney Disease, though may occur as Autosomal Dominant Polycystic Liver Disease.
  - Imaging:
    - For prognostication purposes MRI Abdomen (CPT® 74183) or CT Abdomen (CPT® 74160 or CPT® 74170) can be performed initially to assess liver volume.
    - Surveillance imaging of asymptomatic individuals is not medically necessary.
    - Suspected complications such as cyst rupture or hemorrhage (manifested by acute pain in the upper abdomen):
      - MRI Abdomen (CPT® 74183) or CT Abdomen (CPT® 74160 or CPT® 74170)

Evidence Discussion

Ultrasonography is the first step in diagnosing polycystic liver disease (PLD). Abdominal ultrasound to screen for PLD should be offered to all individuals diagnosed with autosomal dominant polycystic kidney disease (ADPKD). Imaging follow up is not routinely medically necessary in asymptomatic individuals. CT Abdomen or MRI Abdomen may be medically necessary in symptomatic individuals to assess the extent of PLD/cyst burden and to assess the liver volume. MRI or CT can be used in PLD to evaluate the distribution of cysts within the liver parenchyma and the relation to hepatic vasculature. Ultrasound or MRI Abdomen may medically necessary to diagnose cyst hemorrhage, when suspected. CT Abdomen is not medically necessary to diagnose cyst hemorrhage. CT may detect gas or calcification but is less accurate for assessing cyst contents. There is no need to screen family members of individuals with PLD for the presence of hepatic cysts unless symptoms are present. Screening for intracranial aneurysms is not medically necessary for individuals with PCLD. Routine post treatment imaging is not medically necessary.[33-38]

Isolated or Incidental Hepatomegaly (AB-29.4)

AB.LL.0029.4.A

v1.0.2026

- Initial imaging of hepatomegaly discovered or suspected on physical examination:
  - US Abdomen (CPT® 76700 or CPT® 76705) and Duplex (CPT® 93975 or CPT® 93976)
- Further evaluation of abnormalities on initial ultrasound that require further characterization:
  - Refer to specific guidelines for the abnormality detected on US
    - Fatty liver (liver steatosis), see: **Fatty Liver (Metabolic Associated Steatotic Liver Disease (MASLD), formerly known as NAFLD) (AB-29.2)**
    - Hepatic lesion, see: **Liver Lesion Characterization (AB-29.1)**
- Hepatomegaly discovered on ultrasound and no indeterminate abnormalities:
  - Medical workup, including lab studies such as liver tests, and history and physical should be performed to assess for suspected underlying disease (e.g. infiltrative disease such as amyloid, lymphoma, etc.)
    - Lab abnormalities and/or symptoms of a specific disease process should follow imaging studies outlined in the guideline for that disease process.
    - Advanced imaging in the absence of symptoms or lab abnormalities indicative of an underlying disorder is not medically necessary.

Background and Supporting Information

As noted by the AASLD "…imaging tests, such as ultrasound, computed tomography (CT), and MR, do not reliably reflect the spectrum of liver histology in individuals with NAFLD." In addition, "MR imaging, either by spectroscopy or by proton density fat fraction is an excellent noninvasive modality for quantifying hepatic fat and is being widely used in NAFLD clinical trials…..However, the utility of noninvasively quantifying HS (hepatic steatosis) in individuals with NAFLD in routine clinical care is limited."[3]

Evidence Discussion

Hepatomegaly (enlarged liver) can be detected by physical exam and imaging studies, such as ultrasound, CT, MRI and nuclear medicine studies. An enlarged or palpable liver does not always indicate primary liver disease, so advanced imaging should be directed by history, other physical findings and laboratory results.[1,3,14,21]

An enlarged liver can be caused by[1,3,14,21]:

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Primary liver disease (hepatitis, alcoholic liver disease, NAFLD (non-alcoholic fatty liver disease), other causes of liver inflammation
- Metastatic or primary liver tumors
- Infiltrative disease (such as amyloidosis, infiltrative lymphoma)
- Impaired venous outflow (such as right heart failure, Budd-Chiari syndrome)
- Storage disorders (such as Gaucher Disease, Alpha-1 antitrypsin deficiency)
- Polycystic liver disease
- Other less common causes

Initial imaging studies should be chosen based on history, physical exam, laboratory studies and prior imaging studies. Usually, ultrasound of the abdomen and/or duplex scan would be the initial tests. Advanced imaging, such as CT or MRI are likely to be considered medically necessary based on findings based on specific guidelines based on the abnormality detected on ultrasound.[1,3,14,21]

Abnormal Liver Chemistries (AB-30.1)

AB.LC.0030.1.A
v1.0.2026

Elevated AST and/or ALT (>33 IU/l for males [assigned at birth], >25 IU/l for females [assigned at birth]) and other LFTs are normal or Hepatocellular pattern of elevation (AST and ALT disproportionately elevated to ALKP):

- <2X normal:
  - Repeat lab after 3 weeks and discontinuation of medications associated with elevated LFTs (such as statins, niacin, sulfa, rifampin, tetracycline, estrogen) if applicable.
  - If LFTs remain elevated: Abdominal US (CPT® 76700 or CPT® 76705)
    - Above studies do not explain the cause of the elevated transaminases AND HAV IgG, HBsAg, HBcAb, HBsAb, HCV Ab, iron panel (may include ferritin, serum iron, iron-binding capacity, or transferrin saturation) have been performed and are inconclusive:
      - CT Abdomen with contrast (CPT® 74160)
- 2 to 15X normal:
  - Abdominal US (CPT® 76700 or CPT® 76705)
    - Above studies do not explain the cause of the elevated transaminases AND HAV IgG, HBsAg, HBcAb, HBsAb, HCV Ab, iron panel (may include ferritin, serum iron, iron-binding capacity, or transferrin saturation) have been performed and are inconclusive:
      - CT Abdomen with contrast (CPT® 74160)
- >15X normal:
  - Abdominal US with Doppler (CPT® 76700 or CPT® 76705 and CPT® 93975) OR
  - CT Abdomen with contrast (CPT® 74160) OR
  - CT Abdomen and Pelvis with contrast (CPT® 74177)
    - Above studies do not explain the cause of the elevated transaminases AND HAV IgG, HBsAg, HBcAb, HBsAb, HCV Ab, iron panel (may include ferritin, serum iron, iron-binding capacity, or transferrin saturation) have been performed and are inconclusive:
      - MRI Abdomen without and with contrast (CPT® 74183) and/or MRCP (CPT® 74181)

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- If the findings suggest chronic liver disease, see: **Chronic Liver Disease, Cirrhosis and Screening for HCC (AB-26.1)**
- If the findings suggest hemochromatosis, see: **Hereditary (Primary) Hemochromatosis (HH) and Other Iron Storage Disease (AB-11.2)**

Elevated alkaline phosphatase level (or GGT), and other LFTs are normal or Cholestatic pattern of elevation (ALKP elevated disproportionately to AST and ALT)

- If isolated ALKP elevation, GGT should be obtained for confirmation of hepatic etiology, prior to imaging.
- If ALKP is elevated with other LFTs, no confirmatory test is necessary.
    - Confirmed hepatic etiology of elevated ALKP:
        - Abdominal or RUQ ultrasound (CPT® 76700 or CPT® 76705)
            - Dilated biliary ducts on US:
                - MRCP
        - No dilated biliary ducts on US:
            - Anti-mitochondrial antibody (AMA) should be checked prior to advanced imaging.
                - If AMA is negative, and ALKP >2X ULN:
                    - MRCP
                - If AMA is negative, and ALKP 1 to 2X ULN:
                    - observe for 6 months
                    - if ALKP remains elevated after 6 months: MRCP
- CT Abdomen with contrast (CPT® 74160) if the above studies are unrevealing or individual cannot undergo MRCP.

Isolated elevated bilirubin (no other LFTs elevated)

- Elevation is unconjugated (elevated indirect bilirubin), and no other LFT elevations:
    - No advanced imaging
- Elevation is conjugated (elevated direct bilirubin)
    - RUQ ultrasound
        - Dilated biliary ducts on ultrasound:
            - MRCP
        - No dilated biliary ducts on US:

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Anti-mitochondrial antibody (AMA) should be checked prior to advanced imaging
  - AMA negative and elevation persists or is unexplained:
    - MRCP or liver biopsy

- CT Abdomen with contrast (CPT® 74160) if the above studies are unremarkable or the individual cannot undergo MRCP.

Clinical jaundice, no known predisposing condition

- Abdominal ultrasound (CPT® 76700 or CPT® 76705)
  - For further imaging, follow guideline for elevated bilirubin
- Clinical jaundice, suspected mechanical obstruction based on clinical condition or laboratory values (e.g., known choledocholithiasis, acute and chronic pancreatitis, suspected stricture from a recent invasive procedure, previous biliary surgery, suspected tumor):
  - CT Abdomen with contrast (CPT® 74160) or MRI and/or MRCP (CPT® 74183 or CPT® 74181)
- US findings suggesting mechanical biliary obstruction, non- diagnostic or technically limited US (e.g., large amounts of intestinal gas, obesity with BMI >35):
  - CT Abdomen with contrast (CPT® 74160) or MRI and/or MRCP (CPT® 74183 or CPT® 74181)

Additional considerations

- For individuals with elevated LFTs and suspicion of sclerosing cholangitis, such as those with IBD, see: **Primary Sclerosing Cholangitis (PSC) (AB-23.4)**.
- For individuals with elevated LFTs and history of underlying malignancy, please refer to the specific oncology guidelines, when appropriate.
- Requests for additional advanced imaging (CT, MRI, etc.) are based on the prior imaging results, as appropriate to the finding (for example, if a lesion is identified that needs further characterization, refer to liver lesion imaging as per **Liver Lesion Characterization (AB-29.1)**)
- For MRE indications, see: **Liver Elastography (AB-45)**

Background and Supporting Information

- The standard laboratory tests commonly referred to as “LFTs” include bilirubin, alkaline phosphatase (alkphos or ALKP), aspartate transaminase (AST), alanine transaminase (ALT), and gamma-glutamyl transferase (GGT).
- The major patterns of elevation which affect work-up are:
- Hepatocellular (AST and ALT disproportionately elevated to ALKP)

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Cholestatic (ALKP elevated disproportionately to AST and ALT)
- Mixed pattern (ALKP, AST, and ALT all elevated)
- Isolated hyperbilirubinemia (elevated bilirubin and normal ALKP, ALT and AST)
- "R" Ratio
  - "R" Ratio: The so-called "R" ratio can be used to determine whether a pattern of multiple elevated liver chemistries is predominately cholestatic or hepatocellular in origin
  - R=(ALT/Upper limit of normal (ULN))/(ALKPH/ULN ALKPH)
    - If the "R" ratio:
      - >5 = hepatocellular
      - <2 = cholestatic
      - 2-5 = mixed pattern
  - For hepatocellular, use AST or ALT elevation guidelines
  - For cholestatic, use ALKPH elevation guidelines
  - Use ULN for ALT as noted above, and ULN for alkphos based on the individual lab report

Evidence Discussion

Liver blood tests look at how well the liver is functioning and can indicate whether there is any damage or inflammation inside the liver. Obtaining liver chemistries for both screening and diagnostic purposes are essential. When abnormalities are found they will frequently direct the provider to obtain further diagnostic testing including advanced imaging.[1,11]

A liver blood test looks at the chemicals (enzymes), proteins and other substances made by the liver to assess whether levels of any of these are abnormal. The major initial tests are for alanine transaminase, aspartate transaminase, alkaline phosphatase, and gamma-glutamyl transpeptidase.[1,11]

Repeating abnormal tests helps to confirm damage to the liver.[1,11]

The synthetic function of the liver can be assessed by evaluating levels of albumin and vitamin-dependent clotting factors.[1,11]

Iron storage, autoimmune, infectious, cholestatic, hepatocellular, drug induced, and other liver diseases are identified, followed, and diagnosed with the help of abnormal liver chemistries.[1,11]

Liver chemistries are an essential part of the non-invasive diagnosis and management of liver disease.[1,11]

Pancreatic Cystic Lesions (AB-31.1)

AB.PC.0031.1.A
v1.0.2026

- Pancreatic Cyst seen on Imaging-Initial Management:
  - MRI Abdomen (CPT® 74183) and/or MRCP are the tests of choice for initial evaluation.
    - Both MRI Abdomen and MRCP may be medically necessary, but only one CPT® 74183 should be used, not two.
  - CT Pancreatic protocol (CPT® 74160) or EUS are alternatives in individuals who are unable to undergo MRI.
  - Indeterminate cysts may benefit from a second imaging modality or EUS prior to proceeding with surveillance. MRI/MRCP can be approved to better characterize the lesion, without reference to the timeframe for follow-up imaging, if a previous US or CT Abdomen has been performed.
  - Radiographic diagnosis of a non-neoplastic cyst or classic features of a serous cystadenoma
    - No further imaging
  - If ANY of the following are present the individual should proceed to EUS + FNA and depending on findings, surgical consultation:
    - Main duct >5mm
    - Cyst ≥3cm
    - Change in main duct caliber with upstream atrophy
      - If EUS does not reveal findings of main duct involvement, patulous ampulla, cytology with high-grade dysplasia or pancreatic malignancy, or a mural nodule, then follow up MRI should performed in 6 months.
- Pancreatic Cyst Follow up Imaging
  - If high risk features (See below High Risk Considerations and Features) are not present, then the next follow-up imaging proceeds as follows:
    - Cyst <1cm: MRI in 2 years
    - Cyst 1-<2cm: MRI in 1 year
    - Cyst 2-3cm: if cyst is not clearly an Intraductal papillary mucinous neoplasms (IPMN) or Mucinous cystic neoplasm (MCN) then proceed with EUS. If it is an IPMN or MCN, then MRI at 6-12 months.
    - If the cyst is determined to be a serous cystadenoma, then no further evaluation unless symptomatic.
- Additional Surveillance for a presumed Intraductal papillary mucinous neoplasms (IPMN) or Mucinous cystic neoplasms (MCN) (imaging from time of presentation):
  - Cyst <1cm

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- MRI every 2 years for 4 years
- If stable after 4 years consider lengthening of interval imaging
- If increase in cyst size, then MRI or EUS in 6 months
- If stable, repeat again in 1 year and if stable return to MRI every 2 years

◦ Cyst 1-<2cm
- MRI yearly for 3 years
- If stable for 3 years, then change to MRI every 2 years for 4 years
- If stable after the additional 4 years, consider lengthening of interval for surveillance
- If increase in cyst size, repeat MRI in 6 months. If stable, repeat MRI in 1 year and if remains stable, resume original surveillance schedule.

◦ Cyst 2-<3cm
- MRI every 6-12 months for 3 years
- If stable after 3 years, change to MRI every year for 4 years
- If remains stable, consider lengthening of surveillance interval

◦ Cyst ≥3cm
- MRI alternating with EUS every 6 months for 3 years
- If stable for 3 years, increase interval to MRI alternating with EUS yearly for 4 years
- If remains stable, consider lengthening of surveillance interval
- If increase in cyst size, EUS + FNA

◦ Additional considerations
- Individuals with asymptomatic cysts that are diagnosed as pseudocysts on initial imaging and clinical history, or are determined to be serous cystadenomas, do not require further evaluation.
- Individuals who are not medically fit for surgery should not undergo further surveillance of incidentally found pancreatic cysts, irrespective of size.
- Surveillance should be discontinued if an individual is no longer a surgical candidate. However, follow-up imaging can be performed if requested for a symptomatic cyst (such as the development of jaundice secondary to cyst), in which palliative treatment might be available.
- High-Risk Considerations and Features
  - Individuals with IPMNs or MCNs with new onset or worsening diabetes
  - Rapid increase in cyst size (>3mm/year) during surveillance may have an increased risk of malignancy and should undergo a short-interval MRI or EUS.
  - Additional high-risk features which may prompt early evaluation are:
    - jaundice secondary to the cyst
    - acute pancreatitis secondary to the cyst

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

        - significantly elevated CA 19-9
        - presence of a mural nodule or solid component either within the cyst or in the pancreatic parenchyma
        - dilation of the main pancreatic duct >5mm
        - focal dilation of the pancreatic duct concerning for main duct IPMN or an obstructing lesion
        - IPMNs or MCNs measuring ≥3cm in diameter
        - presence of high-grade dysplasia or pancreatic cancer on cytology. In this circumstance, imaging should be at the discretion of the provider.
- Post-op surveillance
    - Surgically resected serous cystadenomas, pseudocyst, or other benign cyst:
        - No additional imaging after resection
    - Surgically resected mucinous cystic neoplasms (MCNs) without an associated pancreatic malignancy (can have low, intermediate, or high-grade dysplasia):
        - No additional post-op surveillance
    - Surgically resected MCNs with invasive cancer:
        - Standard surveillance-based pancreatic cancer guidelines (See: **Pancreatic Cancer-Surveillance/Follow-up (ONC-13.5)** in the Oncology Imaging Guidelines) for 5 years. No surveillance required after 5 years.
    - Surgically resected IPMNs
        - IPMN with cancer
            - Pancreatic cancer surveillance guidelines (See: **Pancreatic Cancer-Surveillance/Follow-up (ONC-13.5)** in the Oncology Imaging Guidelines)
        - IPMN with high-grade dysplasia
            - MRI Abdomen (CPT® 74183) or EUS every 6 months
        - IPMN with low- or intermediate-grade dysplasia
            - MRI Abdomen (CPT® 74183) every 2 years
    - Surgically resected solid-pseudopapillary neoplasm with negative margins:
        - MRI Abdomen (CPT® 74183) yearly for 5 years
- See: **MR Cholangiopancreatography (MRCP) (AB-27)** for coding guidelines for MRCP.

Evidence Discussion

- Some pancreatic cystic lesions have malignant potential and need to be followed by either advanced imaging, endoscopic ultrasound, or both.[1,2,6]
- Advanced imaging includes MRI, MRCP, and CT imaging as these modalities are most effective in characterizing these lesions. MRI abdomen or MRCP are the initial studies of choice. The American Gastroenterological Association states, "MRI is the preferred surveillance imaging modality over computed tomography because MRI does not expose the individual to radiation and better demonstrates the structural

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

relationship between the pancreatic duct and associated cyst. Also, MRI is less invasive than EUS". Thus, CT is reserved as an alternative for individuals who are unable to undergo MRI.[1]

- Follow-up imaging may or may not be medically necessary based on the nature of the cystic lesion, the size, or change in size of the lesion and how rapidly the size of the lesion changes. Smaller lesions with no concerning characteristics or changes undergo less surveillance due to the small absolute risk of malignancy. Concerning features such as rapid increase in size have increased risk of malignancy and therefore undergo more frequent or longer-term surveillance intervals.[1,2,6]

Incidental Pancreatic Mass or Suspected Metastatic Disease to Pancreas (AB-31.2)

AB.PC.0031.2.A

v1.0.2026

- For the evaluation of incidental pancreatic mass or suspected metastatic disease to the pancreas, CT Abdomen with contrast with dual phase imaging (CPT® 74160), or MRI Abdomen without and with contrast (CPT® 74183).

Evidence Discussion

A pancreatic protocol CT involves scan acquisition during a parenchymal and portal venous phase, each of which are post-contrast administration. Dual phase, MDCT (multidetector CT) scans play a critical role in diagnosing and staging pancreatic cancers. MR and EUS can be used in groups of individuals where CT scan results are inconclusive in tumor localization and/or staging, particularly in vascular involvement.[7,8]

Acute Pancreatitis (AB-33.1)

AB.PX.0033.1.A
v1.0.2026

- The presence of any red flag findings per **General Guidelines (AB-1.0)** precludes adjudication based on any other criteria.
- Imaging:
  - Initial imaging for suspicion of pancreatitis (typical symptoms, <48 to 72 hours, first-time presentation)
    - Abdominal ultrasound (CPT® 76700 or CPT® 76705)
      - Purpose is to establish the presence/absence of gallstones and biliary ductal dilation.
      - Doppler ultrasound (CPT® 93975) can be approved to assess vasculature, if requested.
    - If ultrasound or CT is performed and is nondiagnostic due to technical limitation (obesity, overlying gas, etc.):
      - MRI/MRCP (CPT® 74183 or CPT® 74181)
      - CT Abdomen and Pelvis with contrast (CPT® 74177) or CT Abdomen with contrast (CPT® 74160) if ultrasound is nondiagnostic and MRI/MRCP cannot be performed.
    - In suspected acute biliary pancreatitis and/or cholangitis (dilated ducts or choledocholithiasis on ultrasound, elevated liver chemistries with a negative ultrasound, suspicion of cholangitis (classic triad is RUQ pain, fever, and jaundice))
      - MRI/MRCP (CPT® 74183 or CPT® 74181)
  - Initial imaging with atypical signs and symptoms when diagnoses other than pancreatitis are being considered (e.g., bowel perforation, bowel ischemia):
    - CT Abdomen and Pelvis with contrast (CPT® 74177) or CT Abdomen with contrast (CPT® 74160)
    - MRI/MRCP* (CPT® 74181 or CPT® 74183) can be considered medically necessary for pregnant individuals (non-contrast), or those with renal insufficiency (without or without and with depending on request).
  - Follow-up imaging (late phase and thereafter):
    - Continued or worsening symptoms:
      - CT Abdomen and Pelvis with contrast (CPT® 74177), CT Abdomen with contrast (CPT® 74160) or MRI and/or MRCP (CPT® 74183 or CPT® 74181)
    - Follow-up of known pancreatic or peri-pancreatic fluid collections (including pseudocysts), to follow-up symptomatic collections, or for interventional planning:

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- MRI/MRCP (CPT® 74183 or CPT® 74181) or CT Abdomen and Pelvis (CPT® 74177)
  - If requested, CT Abdomen with contrast (CPT® 74160) or Abdominal ultrasound (CPT® 76705 or CPT® 76700) can be approved.

Note:

Frequency or intervals for additional follow-up is not defined and depends on clinical circumstances, response to therapy, etc.

- If, despite initial imaging, the etiology of the pancreatitis is still in doubt:
  - MRI/MRCP (CPT® 74183 or CPT® 74181) or CT Abdomen and Pelvis with (CPT® 74177)
    - If requested, CT Abdomen with contrast (CPT® 74160) can be approved.

- Acute recurrent pancreatitis
  - Abdominal ultrasound (CPT® 76705 or CPT® 76700)
  - MRI/MRCP (CPT® 74183 or CPT® 74181)
  - CT Abdomen and Pelvis with contrast (CPT® 74177)
  - See: **Chronic Pancreatitis (AB-33.2)**

Background and Supporting Information

- While MRI/MRCP will give better evaluation of the pancreatic parenchyma as well as biliary and pancreatic ducts, it does NOT provide coverage and adequate evaluation of the bowel to assess alternative diagnoses such as bowel ischemia or perforation.
- Knowledge base:
  - Acute pancreatitis (2 of 3 of the following criteria):
    - Characteristic abdominal pain (typically epigastric or left upper quadrant pain with radiation to the back, chest, or flank)
    - Amylase or lipase > 3 times the upper limit of normal
    - Radiographic evidence of pancreatitis on cross-sectional imaging
  - Early Phase takes place in the first week
    - Goals of imaging:
      - Establish the correct diagnosis or provide an alternative diagnosis
      - Establish the etiology
      - Stage the morphologic severity
      - Assess for complications in individuals who deteriorate or fail to improve
  - Late phase can last weeks to months thereafter
    - Goals of imaging:
      - Monitor established pancreatic collections
      - Delineate the presence of symptomatic and asymptomatic complications
      - Guide interventional procedures

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Etiologies of pancreatitis:
  - Gallstones and alcohol account for 75-80% of all cases
  - Hypercalcemia, hypertriglyceridemia, medications, a benign or malignant obstruction, pancreatic mass, genetic causes (hereditary pancreatitis), autoimmune pancreatitis (IgG4), infectious etiologies, ischemia secondary to vascular disease, anatomic abnormalities (e.g., pancreas divisum), physiologic abnormalities (Sphincter of Oddi dysfunction), idiopathic causes.
- Complications:
  - Early Phase
    - Generally manifests as a systemic inflammatory response
    - In the first week, imaging findings correlate poorly with clinical severity
    - Advanced imaging is most useful when performed 5-7 days after admission, when local complications have developed and pancreatic necrosis can be clearly defined
    - IEP=acute interstitial edematous pancreatitis
    - Necrotizing Pancreatitis
  - Late Phase:
    - APFC (Acute peripancreatic fluid collection) occurs during the first 4 weeks. If it does not resolve within 4 weeks, it can become organized and develop into a pseudocyst, which contains only fluid with no nonliquefied components.
    - Walled-off necrosis (sequelae of necrotizing pancreatitis): inhomogenous nonliquefied components, encapsulated with a wall.

Note:

Most cases of pancreatitis are mild. More severe cases are usually hospitalized and imaging is performed in that setting. The majority of imaging requests are for the initial evaluation of suspected pancreatitis in individuals with epigastric pain, and then the follow-up imaging of discharged individuals with respect to complications experienced during the hospitalization, to further elucidate the etiology of the pancreatitis if this was not previously established, or to evaluate continued post-discharge symptoms.

Evidence Discussion

Abdominal imaging is useful to confirm the diagnosis of acute pancreatitis (AP). As per 2024 ACG Guidelines, abdominal ultrasound should be performed as the initial imaging study in individuals with AP to evaluate for biliary pancreatitis. Advanced imaging should be reserved for individuals in whom the diagnosis is unclear. When ultrasound results are inconclusive due to overlying bowel gas or other patient factors, or when amylase and/or lipase levels remain elevated, CT or MRI should be considered as the next step. Although contrast-enhanced CT offers over 90% sensitivity and specificity in diagnosing

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

acute pancreatitis, its routine use is not recommended since the diagnosis is clear in many individuals who typically experience a mild, uncomplicated course.[1-5,21]

In individuals who fail to improve after 48–72 hours, exhibiting persistent symptoms such as pain, fever, nausea/vomiting, and inability to tolerate oral feeding, imaging studies like CT or MRI/MRCP are recommended. These are used to assess local complications, including necrotizing pancreatitis or pancreatic or peri-pancreatic fluid collections. Although MRI takes more time and can be challenging for claustrophobic individuals, it offers advantages for those with contrast allergies or renal insufficiency. Additionally, MRI can more accurately detect stones in the common bile duct (CBD) and diagnose pancreatic duct disease or follow up on symptomatic fluid collections.[1-5,21]

Chronic Pancreatitis (AB-33.2)

AB.PX.0033.2.A

v1.0.2026

- The presence of any red flag findings per **General Guidelines (AB-1.0)** precludes adjudication based on any other criteria.
- If chronic pancreatitis is suspected:
  - Initial imaging:
    - CT Abdomen with contrast or without and with contrast (CPT® 74160 or CPT® 74170) OR MRI Abdomen without and with contrast (CPT® 74183)
      - If diagnostic criteria are met (pancreatic calcification in combination with pancreatic atrophy and/or dilated pancreatic duct):
        - No further imaging indicated (See below regarding worsening symptoms)
    - If initial CT is inconclusive or nondiagnostic of chronic pancreatitis:
      - MRI/MRCP with secretin enhancement (CPT® 74183 or CPT® 74181), OR
      - Endoscopic ultrasound (EUS)
    - If EUS is inconclusive, pancreatic function testing and/or ERCP is medically necessary
    - If abdominal ultrasound is requested at any stage for evaluation of chronic pancreatitis, this can be approved in lieu of advanced imaging
  - If initial imaging fails to confirm chronic pancreatitis, but the clinical suspicion remains, the above testing can be repeated in 6 months.
- Known chronic pancreatitis with worsening symptoms or pain:
  - CT Abdomen with or without and with contrast (CPT® 74160 or CPT® 74170), MRI/MRCP (CPT® 74183 OR CPT® 74181) OR Abdominal ultrasound (CPT® 76700 or CPT® 76705) is medically necessary
  - Possible etiologies of worsening pain include:
    - peptic ulcer disease
    - GI cancers
    - pseudocysts
    - duodenal or common bile duct obstruction
    - pancreatic duct stone or strictures
    - inflammatory masses at the head of the pancreas
- For pre-surgical planning or post-surgical evaluation for treatment of complications of chronic pancreatitis
  - CT Abdomen with or without and with contrast (CPT® 74160 or CPT® 74170), OR MRI/MRCP (CPT® 74183 or CPT® 74181) OR Abdominal ultrasound (CPT® 76700 or CPT® 76705)
- Routine screening for pancreatic cancer in chronic pancreatitis

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Routine surveillance to monitor for the occurrence of pancreatic cancer in individuals with chronic pancreatitis is not supported at this time. For other indications for imaging in chronic pancreatitis, see the above. For pancreatic cancer screening guidelines in inherited syndromes, including hereditary pancreatitis, see: **Screening Studies for Pancreatic Cancer (ONC-13.1)** in the Oncology Imaging Guidelines.

Background and Supporting Information

- Clinical signs of chronic pancreatitis include history of alcohol use, abdominal pain, weight loss, steatorrhea, malabsorption, recurrent pancreatitis, fatty food intolerance, low fecal elastase.

Evidence Discussion

CT or MRI is used as first-line diagnostic imaging for chronic pancreatitis (CP) as they are both universally available, reproducible, and valid when compared to other imaging modalities. While ultrasound has been used for many years as a non-invasive and inexpensive method to evaluate the pancreas, there are considerable limitations that limit its diagnostic utility.[8,13]

Due to its discrepancy in cost, availability, invasiveness, and objectivity, as well as its low specificity, endoscopic ultrasound (EUS) should be used only if the diagnosis is still in question after cross-sectional imaging is performed.[8,13]

Individuals with early CP may have completely normal conventional MRCP/MRI studies, and only the secretin stimulation will depict the mildly abnormal pancreatic duct compliance.[8,13]

When the diagnosis of CP cannot be made following standard cross-sectional imaging or EUS, secretin-enhanced MRCP is suggested as it allows for better visualization of the main- and side-branch ducts by stimulating release of bicarbonate from the pancreatic duct cells and allows for quantification of the degree of filling into the duodenum which may correlate with the severity of CP and also help quantify the degree of exocrine pancreatic function. It does carry a high cost, which is why it is recommended to be used only when diagnosis is not confirmed with first-line testing. However, EUS does carry poor interobserver agreement, and definitive diagnosis is felt to also require advanced radiologic imaging. It is also a more invasive procedure. For this reason, there are also practice guidelines that advocate for the use of MRI/MRCP with secretin enhancement prior to EUS.[8,13]

While multiple other imaging modalities, such as contrast-enhanced EUS, ERCP, transcutaneous ultrasonography, and pancreatic elastography have been used to establish the diagnosis of CP, high-quality RCT evidence is not available to warrant their inclusion as first-line diagnostic tests for CP.[8,13]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

As noted in the American College of Gastroenterology Clinical Guideline for Chronic Pancreatitis, "There is a lack of evidence to suggest that performing screening examinations on individuals with CP (chronic pancreatitis) to detect malignancy is beneficial. Although the overall prevalence of pancreatic malignancy is increased in individuals with CP, there are no RCTs (randomized controlled trials), systematic reviews, or meta-analyses to support screening this individual population for pancreatic malignancy." As such, the ACG Guideline concludes "at this time there is no definitive benefit to screen individuals with CP for pancreatic ductal adenocarcinoma. This is based on the invasive and costly nature of testing, the inherent difficulty in screening given the structural changes of CP, and the inability to alter in many cases the natural history of the disease even if malignancy is detected at an early stage."[13]

Exocrine Pancreatic Insufficiency (AB-33.3)

AB.PX.0033.3.A
v1.0.2026

- The presence of any red flag findings per **General Guidelines (AB-1.0)** precludes adjudication based on any other criteria.
- Pancreatic Insufficiency
  - The initial evaluation for pancreatic insufficiency should include ONE of the following laboratory results:
    - Elevation in fecal fat
    - Fecal elastase <200 mcg/g
    - Serum trypsinogen <20ng/mL
  - CT Abdomen with (CPT® 74160) or without and with contrast (CPT® 74170) OR MRI/MRCP (CPT® 74183 or 74181) for the evaluation of suspected pancreatic insufficiency:
    - for suspected pancreatic insufficiency with any one of the above laboratory findings
  - For suspected pancreatic insufficiency due to known chronic pancreatitis, see: **Chronic Pancreatitis (AB-33.2)**
  - For suspected pancreatic insufficiency due to known cystic fibrosis, see: **(PEDAB-16)** and **(PEDCH-5.1)**
  - For suspected pancreatic cancer, see: **Pancreatic Cancer – Suspected/ Diagnosis (ONC-13.2)**

Background and Supporting Information

- Exocrine pancreatic insufficiency (EPI) reflects reduced pancreatic enzymes with resulting maldigestion/malabsorption. When intraduodenal levels of lipase fall below 5-10% of normal output, individuals may manifest with abdominal pain, bloating/ cramping, flatulence, and progressive steatorrhea.

Evidence Discussion

Fecal elastase is the most appropriate initial test for exocrine pancreatic insufficiency (EPI) with a level <100 ug/g of stool providing good evidence of EPI, and levels of 100-200 ug/g being indeterminate for EPI. It is an indirect measurement that is simple, noninvasive, and relatively non-expensive. While direct measurements of pancreatic secretions in to the duodenum are accurate, they are invasive, time-consuming and a more significant burden to the patient than this indirect test.[24]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Quantitative fecal fat testing is generally not practical for routine clinical use.[24]

While cross-sectional imaging methods such as CT and MRI/MRCP cannot be used to solely identify EPI, they play an important role in the diagnosis of both benign and malignant pancreatic disease, and can also identify gross pancreatic structural changes. Cross-sectional imaging is thus useful for diagnosing underlying pancreatic disease as well as abnormalities that may support an EPI diagnosis.[24]

EPI develops in more than half of individuals with chronic pancreatitis, 27-62% of individuals with relapsing acute pancreatitis, 85% of individuals with cystic fibrosis, and 50-92% of individuals with unresectable pancreatic ductal adenocarcinoma. It is seen in 40-50% of individuals with resectable pancreatic ductal adenocarcinoma before treatment and 65% after treatment. It should thus be suspected in these individuals.[24]

Asymptomatic Elevation of Pancreatic Enzymes (AB-33.4)

AB.PX.0033.4.A
v1.0.2026

- If there is the incidental elevation of amylase or lipase:
  - If isolated amylase elevation, prior to imaging, the source of the elevation should be confirmed as pancreatic by the performance of amylase isoenzymes demonstrating that the source is not salivary, or the absence of macroamylase should be ascertained by blood test.
  - If the lipase is elevated alone or in combination with an elevated amylase, or If the amylase is confirmed as pancreatic in origin:
    - Abdominal Ultrasound is medically necessary initially.
    - If US is inconclusive, nondiagnostic, or the elevated pancreatic enzymes persist:
      - MRI/MRCP is medically necessary (CPT® 74183).
        - It is best performed as a secretin-stimulation test in this setting.
      - CT Abdomen (pancreatic protocol, CPT® 74160) is medically necessary if there is a contraindication to MRI.
  - If the pancreatic enzyme elevation persists at one year, either of the above studies can be repeated.

Evidence Discussion

Abdominal imaging is required for the differential evaluation of elevated serum amylase and/or lipase levels and can confirm the diagnosis of acute pancreatitis. Biliary duct dilation and stone disease are readily apparent on an ultrasound, which should be performed as the initial imaging study.[21-23]

When ultrasound results are inconclusive due to overlying bowel gas or other patient factors, or when amylase and/or lipase levels remain elevated, CT or MRI should be considered as the next step. Although contrast-enhanced CT offers over 90% sensitivity and specificity in diagnosing acute pancreatitis, its routine use is not recommended since the diagnosis is clear in many individuals who typically experience a mild, uncomplicated course.[21-23]

Spleen (AB-34.1)

AB.SP.0034.1.A
v1.0.2026

- Incidental splenic findings on US:
  - CT Abdomen (CPT® 74170) or MRI Abdomen (CPT® 74183) is medically necessary.
- Incidental splenic findings on CT or MRI:
  - Imaging is diagnostic of a benign lesion (simple cyst, hemangioma) or characteristics are benign-appearing (homogeneous, low attenuation, no enhancement, smooth margins):
    - No follow-up imaging
  - Imaging characteristics are not diagnostic:
    - Prior imaging available:
      - One year stability: no follow up imaging
      - Lack of stability: consider MRI if not done, biopsy, or PET/CT (CPT® 78815).
    - No prior imaging:
      - No known malignancy:
        - Suspicious imaging features: (suggesting possible malignancy)
          - MRI Abdomen (CPT® 74183) if not already done or biopsy
          - If MRI still inconclusive and biopsy is not feasible then PET/CT (CPT® 78815) is medically necessary.
        - Indeterminate imaging features: (equivocal but not suspicious for malignancy)
          - Follow up MRI Abdomen (CPT® 74183) in 6 and 12 months.
      - Known malignancy:
        - <1 cm: follow up MRI Abdomen (CPT® 74183) in 6 and 12 months.
        - ≥1 cm: consider MRI Abdomen (CPT® 74183) if not done, biopsy
          - If MRI still inconclusive and biopsy is not feasible then PET/CT (CPT® 78815) is medically necessary.
        - (See diagnosis-specific in the *Oncology Imaging Guidelines*).
- Clinically detected splenomegaly
  - Abdominal US (CPT® 76700 or CPT® 76705) should be the first imaging study to evaluate splenic size.
  - If splenomegaly is confirmed, the following evaluation is medically necessary prior to advanced imaging:
    - CBC, evaluation of the peripheral blood smear, LFTs, UA, chest x-ray, HIV testing.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- CT Abdomen without and with contrast or with (CPT® 74170 or CPT® 74160) is medically necessary if the etiology of the splenomegaly remains unexplained.
- MRI Abdomen (CPT® 74183) is medically necessary for pregnant individuals, or individuals with iodinated contrast allergy.

◦ Nuclear medicine imaging of the liver/spleen (CPT® 78201, CPT® 78202, CPT® 78803, CPT® 78215, CPT® 78216, or CPT® 78830) is rarely performed, but is medically necessary if CT and MRI are contraindicated, as well as for evaluation of an accessory spleen.

Background and Supporting Information

These guidelines are consistent with ACR recommendations for the follow-up of incidental splenic masses. It is noteworthy, however, that a recent study from Beth Israel Deaconess Medical Center in which the authors retrospectively reviewed 379 individuals who were found to have an incidental splenic mass on CT found that in individuals without a history of malignancy, constitutional symptoms of fever or weight loss, or left upper quadrant or epigastric pain (205/379) there were 2 incidences of malignancy. However, in both of these cases the splenic masses were neither isolated nor indeterminate findings as the CTs demonstrated disease in other locations. An isolated splenic malignancy (which can occur but is very rare) was found only in 2 individuals and both of these had constitutional symptoms. Thus, the authors claim that “the isolated and incidentally found splenic mass is of unlikely clinical significance, regardless of its appearance.” They concluded that “in individuals with an incidental splenic mass identified at imaging and with the absence of a history of malignancy, fever, weight loss, or pain in the left upper quadrant or epigastrium, such masses are highly likely to be benign regardless of their appearance. Additional imaging or follow-up is not medically necessary, even if the mass does not show the appearance of simple cyst. Further work-up is only needed if the splenic mass is seen in conjunction with other findings worrisome for malignancy.” These authors challenge the use of the ACR guidelines.

Evidence Discussion

- Splenomegaly is usually the result of systemic disease, and diagnostic studies should be directed toward identifying the etiology. Ultrasound is the preferred modality for documentation of splenomegaly found on physical exam. If the etiology of the splenomegaly is determined (benign or malignant), follow-up imaging would be addressed relative to that disease process.[10]
- The accuracy, cost-effectiveness, and lack of radiation make abdominal ultrasonography a first-line step for confirmation of size.[10]
- Both CT and MRI are valid studies for initial evaluation and follow-up of indeterminate splenic lesions due to the non-specific hypoechogenicity found on ultrasound. These

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

should be performed both with and without contrast to improve diagnosis of a solid organ lesion. Nuclear medicine imaging is rarely needed but has a role in detection of accessory splenic lesions.[11]

- There is no evidence-based data supporting the use of serial CT or MRI scans to monitor individuals with incidental splenic lesions that have benign characteristics or lesions that are stable after one year.

Splenic Trauma (AB-34.2)

AB.SP.0034.2.A

v1.0.2026

- Ultrasound Abdomen (CPT® 76700 or CPT® 76705) and Pelvis (CPT® 76856 or CPT® 76857) or CT Abdomen and Pelvis without and with contrast (CPT® 74178) or CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary for ANY of the following:
  - Blunt abdominal trauma with suspected splenic rupture, OR
  - Suspected post-procedural splenic injury, OR
  - Individuals with penetrating trauma to the left upper quadrant. See: **Blunt Abdominal Trauma (AB-10)**

Background and Supporting Information

Splenomegaly is usually the result of systemic disease, and diagnostic studies are directed toward identifying the causative disease. Complete blood count with differential, LFT's, and peripheral blood smear examination are often performed prior to considering advanced imaging. There is no evidence-based data to support performing serial CT or MRI to follow individuals with incidental splenic lesions.

Evidence Discussion

Spleen being a vascular organ, prompt diagnosis and management of potentially life-threatening bleeding is the primary goal. Emergency splenectomy remains a life-saving procedure; hence, the goal of imaging is to utilize abdominal imaging to determine injury to organs and vasculature with speed and accuracy. Thus, CT and ultrasound (US) are the primary imaging methods to determine splenic injury.[4,6]

US is useful in trauma individuals as it is able to rapidly determine the presence of fluid in peritoneal space. However, it cannot rule out injury to organs with accuracy.[4,6]

CT scan has increased sensitivity and specificity for organ and vascular injury and for identifying individuals a surgical approach. CT is highly sensitive for identifying significant intra-abdominal pathology (97 to 98 percent sensitivity and 97 to 99 percent specificity).[4,6]

Although a noncontrast CT scan may demonstrate sub-capsular hematoma or hemoperitoneum, a contrast-enhanced CT is better able to demonstrate parenchymal and vascular injuries.[4,6]

MRI is not recommended as an imaging study of choice because it is time-consuming to perform and is not as readily accessible as the imaging methods mentioned above (especially in hemodynamically unstable individuals).[4,6]

Indeterminate Renal Lesion (AB-35.1)

RL.AB.0035.1.A
v1.0.2026

- Incidental Renal Mass on Ultrasound
  - If categorized as simple cyst or Bosniak I or II, no further imaging is medically necessary.
  - Otherwise ONE of the following is medically necessary:
    - CT Abdomen without and with contrast (CPT® 74170)
    - MRI Abdomen without and with contrast (CPT® 74183)
    - Contrast-Enhanced Ultrasound (CPT® 76978) for one lesion
    - Targeted Dynamic Ultrasound (CPT ® 76979) if more than one lesion
- CT Abdomen without and with contrast (CPT® 74170) or MRI Abdomen without and with contrast (CPT® 74183) is medically necessary for further characterization if the original study reveals incomplete visualization of a renal lesion (for example, if only partially visualized on a CT Chest).
- Incidental Renal Mass on CT
  - If characterized as heterogeneous (thick or irregular wall, mural nodule, septa, or calcification):
    - Considered indeterminate. MRI Abdomen without and with contrast (CPT® 74183) OR CT Abdomen without and with contrast (CPT® 74170) is medically necessary
  - If characterized as homogeneous (thin or imperceptible wall, NO mural nodule, septa, or calcification):
    - 10 to 20 HU (Hounsfield units)
      - Likely benign, not fully characterized: no further work-up
    - 21 to 69 HU
      - Indeterminate: MRI Abdomen without and with contrast (CPT® 74183) OR CT Abdomen without and with contrast (CPT® 74170) is medically necessary
    - ≥70 HU
      - Hemorrhagic or proteinaceous cyst, unlikely to be neoplastic: no further work-up
  - If characterized as TSTC (too small to characterize) and homogeneous:
    - If labeled likely benign cyst, not fully characterized:
      - No further work-up
    - If labeled inconclusive based on subjective evaluation:
      - Considered indeterminate. MRI Abdomen without and with contrast (CPT® 74183) (preferred) OR CT Abdomen without and with contrast (CPT® 74170)

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

is medically necessary ideally within 6-12 months but no sooner than 6 months.

- Incidental cystic renal mass on CT or MRI without and with contrast (completely characterized, and does NOT contain fat)
  - Bosniak I (benign simple) or II (minimally complicated)
    - No further work-up
  - Bosniak IIF
    - CT Abdomen without and with contrast (CPT® 74170) or MRI Abdomen without and with contrast (CPT® 74183) is medically necessary at 6 and 12 months, then yearly for 5 years
    - If no changes for 5 years, cyst is considered benign and of no clinical significance
  - Bosniak III or IV should be referred for additional management or if chosen, active surveillance see: **Surveillance (ONC-17.4)** in the Oncology Imaging Guidelines
- Incidental solid renal mass or incidental mass too small to characterize evaluated on CT or MRI without and with contrast and does NOT contain fat
  - TSTC (too small to characterize)
    - If labeled likely benign cyst:
      - No further work-up
    - If labeled inconclusive based on subjective evaluation:
      - MRI Abdomen without and with contrast (CPT® 74183) (preferred), OR CT Abdomen without and with contrast (CPT® 74170) is medically necessary ideally within 6-12 months but no sooner than 6 months.
  - If solid mass <1.0cm
    - MRI Abdomen without and with contrast (CPT® 74183) (preferred), OR CT Abdomen without and with contrast (CPT® 74170) is medically necessary beginning at 6 months, then yearly for 5 years
    - If stable at 5 years (average growth ≤3mm per year): No further work-up
    - If mass shows growth (≥4mm per year) or morphologic change: refer for management, consider renal biopsy. If biopsy is technically challenging or relatively contraindicated, a T2 weighted image MRI Abdomen without and with contrast (CPT® 74183) is medically necessary
  - Solid mass 1.0-4.0cm:
    - Considered a small renal neoplasm: refer for management, consider biopsy. If biopsy is technically challenging or relatively contraindicated, a T2 weighted imaging MRI Abdomen without and with contrast (CPT® 74183) is medically necessary. If active surveillance chosen due to limited life expectancy or co-morbidities, see: **Surveillance (ONC-17.4)** in the Oncology Imaging Guidelines
  - Solid renal mass >4.0cm

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

        - Considered a renal neoplasm: refer for management, or biopsy. If biopsy is technically challenging or relatively contraindicated, a T2 weighted image MRI Abdomen without and with contrast (CPT® 74183) is medically necessary. If active surveillance chosen due to limited life expectancy or co-morbidities, see: **Surveillance (ONC-17.4)** in the Oncology Imaging Guidelines
- Incidental renal mass containing fat (contains a region of interest measuring <-10 HU on CT)
  - No calcification angiomyolipoma (AML)
    - Solitary and without documentation of growth:
      - <4cm: no further work-up
        - If no prior imaging study for comparison, one follow-up MRI Abdomen (CPT® 74183) OR CT Abdomen (CPT® 74170) can be repeated in 6-12 months to assess for any growth.
      - ≥4cm, and considered an AML with potential for clinical symptoms: refer for management.
    - Multiple lesions or growth documented based on old studies:
      - Refer for management. If active surveillance chosen due to limited life expectancy or co-morbidities, see: **Surveillance (ONC-17.4)** in the Oncology Imaging Guidelines.
  - With calcification (suspected renal cell carcinoma):
    - CT Abdomen without and with contrast (CPT® 74170) OR MRI Abdomen without and with contrast (CPT® 74183) is medically necessary if only a non-contrast CT has been performed. If active surveillance is chosen due to limited life expectancy or co-morbidities, see: **Surveillance (ONC-17.4)** in the Oncology Imaging Guidelines.
- Active Surveillance: For all Active Surveillance indications, see: **Surveillance (ONC-17.4)** in the Oncology Imaging Guidelines

Note: PET/CT or PET/MRI are not considered medically necessary because their role evaluating the incidental renal mass is limited.

Bosniak Classification:

I- Benign simple cyst with a hairline thin wall without septa, calcification, or solid component. Homogeneous near-water attenuation density (10 to 20 HU) without enhancement.

II- Benign minimally complicated cyst that may contain a few hairline thin septa that may have “perceived” but not measurable enhancement. Fine calcification or a segment of slightly thickened calcification may be present in the wall or septa. Also, a well-marginated nonenhancing homogeneous mass <3cm with density above simple fluid attenuation (hyperdense cyst).

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

IIF- Usually benign complicated renal cyst with multiple hairline thin septa or minimal smooth thickening of the wall or septa. Wall or septa may contain thick and nodular calcification and may have “perceived” but not measurable enhancement. Also, a well-marginated intrarenal nonenhancing mass >3cm with density above simple fluid.

III -Indeterminate complicated cystic renal mass with thickened irregular walls or septa that have measurable enhancement.

IV-Malignant cystic renal mass with enhancing soft tissue components (cystic renal cell carcinoma).

Evidence Discussion

Advantages of ultrasound includes universal availability, portability, and lack of ionizing radiation. Doppler ultrasound can distinguish between cystic and solid lesions, as well as characterize the quality, presence, and velocity of flow. Therefore, ultrasound can classify a lesion as either a simple cyst or a Bosniak I or II, eliminating the need for further imaging.[1,9,10]

The American Urological Association recommends that individuals with a solid or complex cystic renal mass obtain high quality, multiphase, cross-sectional abdominal imaging to optimally characterize any renal lesion seen on ultrasound, or found incidentally on other imaging studies or non-contrast enhanced abdominal imaging.[1,9,10]

Advanced imaging techniques such as computer tomography (CT) and magnetic resonance imaging (MRI) offer excellent 3-dimensional resolution. CT scans expose individuals to a significant dose of ionizing radiation; however, their rapid image acquisition reduces the potential for motion artifacts. In contrast, MRI provides better soft tissue contrast resolution than CT and does not involve ionizing radiation exposure. Yet, its longer imaging times make it prone to motion artifacts and may necessitate sedation. Additionally, MRIs are contraindicated for individuals with non-MRI compliant implants or ferromagnetic foreign bodies.[1,9,10]

Pre-operative Assessment for Robotic Kidney Surgery (AB-35.2)

RL.AB.0035.2.A
v1.0.2026

- Pre-operative assessment for robotic kidney surgery is medically necessary as follows:
  - If not previously performed:
    - CT Abdomen without and with contrast (CPT® 74170) OR
    - MRI Abdomen without and with contrast (CPT® 74183)
  - CTA Abdomen (CPT® 74175) or CTA Abdomen and Pelvis (CPT® 74174) OR
  - MRA Abdomen (CPT® 74185), or MRA Abdomen and Pelvis (CPT® 74185 and CPT® 72198)

Evidence Discussion

Robotic kidney surgery is typically performed for renal masses. Preoperative imaging is essential for:[10]

- Characterizing a renal mass
- Assessing local extension
- Evaluation vascular anatomy
- Planning surgical approach.

CT Abdomen and pelvis without and with contrast is appropriate and provides detailed anatomical and vascular information.[10]

- CT scans expose individuals to a significant dose of ionizing radiation; however, their rapid image acquisition reduces the potential for motion artifacts.[10]

MRI Abdomen without and with contrast is also medically necessary and can be used as an alternative to CT in individuals with contrast allergy or renal insufficiency.[10]

- MRI provides better soft tissue contrast resolution than CT and does not involve ionizing radiation exposure.[10]

Click Here to Return to the Main TOC

Renal Failure (AB-36.1)

AB.RF.0036.1.A
v1.0.2026

- Initial evaluation of acute or chronic renal failure with EITHER of the following:
  - Ultrasound kidney and bladder (CPT® 76770 or CPT® 76775)
  - Doppler Ultrasound (CPT® 93975 or CPT® 93976)
- MRA Abdomen (CPT® 74185) is medically necessary when there is suspected:
  - renal vein/caval thrombosis OR
  - renal artery stenosis as cause of renal failure
- CT Abdomen without contrast (CPT® 74150) is not medically necessary except to rule out ureteral obstruction or retroperitoneal mass.
- Nuclear renal imaging (CPT® 78701, CPT® 78707, CPT® 78708, CPT® 78709) is medically necessary for ANY of the following:
  - Renal transplant follow-up
  - Kidney salvage vs. nephrectomy surgical decisions
  - Acute renal failure with no evidence of obstruction on recent ultrasound.
  - Chronic renal failure to estimate prognosis for recovery.
- Nuclear medicine studies of the kidney (CPT® 78700 or CPT® 78701) are medically necessary for evaluation of the following anatomic renal anomalies:
  - Suspected horseshoe kidney OR
  - Suspected solitary or ectopic kidney

Evidence Discussion

The main role of imaging is to detect treatable causes of renal failure such as ureteral obstruction or renovascular disease and to evaluate renal size and morphology. Ultrasound is the modality of choice for initial imaging, with duplex Doppler reserved for suspected renal artery stenosis or thrombosis. ACR appropriateness criteria states that ultrasound contrast media are not nephrotoxic, ultrasound has the greatest diagnostic value in the detection of hydronephrosis, and ultrasound is highly sensitive for hydronephrosis and bladder distention. It also allows for evaluation of general information about the kidney such as size and shape. CT may be appropriate, particularly for urinary tract obstruction. CT is useful in determining the cause of hydronephrosis by demonstrating if mass or obstruction is present and at what level in the urinary tract. MRA is useful when renovascular causes of failure are suspected. MRA has shown to be able to detect renal artery stenosis. However, the use of iodinated and gadolinium-based contrast should be evaluated critically depending on specific patient factors and cost-benefit ratio.[1,3]

Tc-99m dimercaptosuccinic acid (DMSA) scintigraphy is ideal for functional renal cortical imaging and is most useful for detection of focal renal parenchymal abnormalities and scars in the setting of acute or chronic pyelonephritis or for differential renal function.[1,3]

Tc-99m mercaptoacetyltriglycine (MAG3) is the most frequently used renal tubular agent, specifically to quantify renal tubular extraction.[1,3]

Click Here to Return to the Main TOC

Polycystic Kidney Disease (AB-38.1)

AB.PK.0038.1.A

v1.0.2026

- Retroperitoneal ultrasound (CPT® 76770 or CPT® 76775) is medically necessary for:
  - suspected polycystic kidney disease OR
  - screening individuals at risk for autosomal dominant polycystic disease (ADPKD)
    - In the absence of any clinical change, follow-up screening is not medically necessary if a screening ultrasound was performed at age 40 or later and was negative for any cysts. (The negative predictive value of an ultrasound in this age group is 100% for both PKD1 and PKD2, if no cysts are identified.)
    - If an initial ultrasound is negative for any cysts, a follow-up ultrasound is medically necessary at the discretion of the ordering provider for individuals <40 years of age.
- MRI Abdomen without contrast (CPT® 74181) is medically necessary:
  - if a cystic renal lesion is detected in an individual at-risk of PKD, for prognostic purposes
  - for volume averaging (Total Kidney Volume – TKV) prior to medical treatment and for post treatment follow-up for PKD.

Background and Supporting Information

- Ultrasound is very effective in establishing a diagnosis of ADPKD, though may miss early small cysts. However, the negative predictive value in the various age groups of a negative ultrasound is as follows:
  - ≥40: 100% for PKD1 and PKD2
  - 30-39: 100% for PKD1 and 96.8% for PKD2
  - 5-29: 99.1% for PKD1 and 83.5% for PKD2
- In addition, the preferable advanced imaging study is MRI Abdomen without contrast (CPT® 74181). This is because of the increased risk of gadolinium-induced nephrogenic fibrosis in individuals with PKD.

Evidence Discussion

Screening studies are important for individuals at risk for polycystic kidney disease, as well as imaging protocols to assess and monitor renal parenchyma and evolving cysts, which can predict patient outcomes.[1]

Screening protocols that utilize ultrasonography, a readily available and safe imaging modality, can reliably quantify and characterize renal cysts, aiding in the diagnosis of ADPKD. A negative ultrasound result has a high negative predictive value for excluding ADPKD.[1]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

After diagnosis, advanced imaging may be medically necessary to assess total kidney volume, and to characterize cystic renal lesions, such as before treatment/procedures Optimal follow-up imaging intervals in this setting have not yet been established. Requests for follow-up imaging can be considered on a case-by-case basis. [5]

Given the significant association with CKD, contrast (both gadolinium and iodine-based) would preferentially be avoided for both CT and MR. The choice of advanced imaging would typically be magnetic resonance imaging without contrast unless the benefits outweigh the risks.[1]

Hematuria with Urinary Tract Infection (UTI) (AB-39.1)

AB.HH.0039.1.A

v1.0.2026

- Individuals suspected to have a UTI as the etiology of microscopic hematuria should be treated for the UTI and should then undergo repeat urinalysis to confirm resolution of the hematuria.
- If the hematuria persists following treatment of UTI, proceed with the risk-based evaluation as per **Asymptomatic Hematuria (AB-39.2)**.

Background and Supporting Information

- Signs and symptoms of UTI: urinary frequency, burning on urination, urgency, dysuria, positive urine leukocyte esterase, presence of WBCs in the urine, fever, elevated WBC as per the testing laboratory's range

Evidence Discussion

An individual who is diagnosed with microscopic hematuria, defined by the American Urological Association guidelines as 3 or more RBC/HPF, and is found to have a concomitant urinary tract infection should have a repeat urinalysis to confirm resolution of the hematuria based on the AUA guidelines.[6]

If microscopic hematuria persists after treatment of the infection, the individual should undergo risk assessment based on the AUA guidelines which provide guidance on the use of advanced imaging.[6]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Asymptomatic Hematuria (AB-39.2)

AB.HH.0039.2.A
v1.0.2026

- A positive dipstick should prompt a microscopic examination.
- Microscopic hematuria is defined as ≥3 red blood cells per high power field.
- Prior to imaging for the evaluation of microscopic hematuria, individuals should be stratified into low, intermediate, or high risk, based on the following criteria:
  - Low risk (individual meets ALL criteria listed)
    - Women <50 years of age or Men <40 years of age
    - Never smoker or <10 pack years
    - 3-10 RBC/HPF on a single urinalysis
    - No additional risk factors for urothelial cancer:
      - Irritative lower urinary tract symptoms
      - Prior pelvic radiation therapy
      - Prior cyclophosphamide/ifosfamide chemotherapy
      - Family history of urothelial cancer or Lynch Syndrome
      - Occupational exposures to benzene chemicals or aromatic amines (e.g. rubber, petrochemicals, dyes)
      - Chronic indwelling foreign body in the urinary tract
  - Intermediate risk (individual meets ANY ONE of these criteria)
    - Women age 50-59 years, Men age 40-59 years
      - 10-30 pack years of smoking
      - 11-25 RBC.HPF on a single urinalysis
      - Low-risk individual with no prior evaluation and 3-10 RBC/HPF on repeat urinalysis
      - Any one of the additional risk factors for urothelial cancer (see above)
  - High-risk (individual meets ANY ONE of these criteria)
    - Women or Men ≥60 years
    - >30 pack-years of smoking
    - >25 RBC/HPF on a single urinalysis
    - Gross hematuria
- Low- or intermediate-risk individuals:
  - Renal ultrasound (combined with cystoscopy)
    - Low-risk individuals may opt for observation with repeat urinalysis within 6 months. If no imaging was performed initially, and follow-up urinalysis reveals persistent hematuria with 3-10 RBC/HPF the individual may be imaged according to Intermediate-Risk criteria. If >10 RBC/HPF, they should be imaged according to High-risk guidelines.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- High-risk individuals
  - CT Urogram (CPT® 74178) is medically necessary (3D imaging is appropriate if requested)
    - If CT is contraindicated, MR Urography is medically necessary (CPT® 74183 and 72197)
      - If both CT and MR are contraindicated due to contrast, non-contrast CT Urography or renal ultrasound should be performed. See also: **Pregnancy Considerations for Imaging (AB-1.12)**.
- Persistent microscopic hematuria if previously evaluated by renal ultrasound
  - Imaging as per High-risk individuals above
- For the evaluation of microscopic hematuria in individuals with inherited risk factors for renal cortical tumors, ONE of the following imaging studies is medically necessary:
  - Renal ultrasound OR
  - CT Abdomen without and with contrast (CPT® 74170) OR
  - MRI Abdomen without and with contrast (CPT® 74183)

Note:

Inherited risk factors for renal cortical tumors include:

- Von Hippel Lindau
- Birt-Hogg-Dube
- Hereditary Papillary Renal Cell Cancer
- Hereditary Leiomyomatosis Renal Cell Cancer
- Tuberous Sclerosis

- Follow-up
  - Individuals with a negative hematuria evaluation who undergo repeat urinalysis
    - If repeat urinalysis is negative:
      - No further workup
    - If repeat urinalysis demonstrates persistent hematuria
      - Repeat imaging as requested (Renal Ultrasound or CT Urography)
- **Note:** 3-D Reconstruction enhances a CT Urogram. Requests for 3-D reconstruction (CPT® 76377 or 76376) for a CT Urogram can be considered medically necessary.

Evidence Discussion

- Microscopic hematuria is defined as ≥3 red blood cells per high power field. Hematuria is NOT defined as a positive dipstick. A positive dipstick should prompt a microscopic examination. A positive dipstick is not considered as defining microhematuria.[6]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Low-risk individuals with microscopic hematuria may opt for a repeat urinalysis prior to proceeding to a workup. Intermediate-risk and high-risk individuals should undergo a workup with upper and lower tract imaging.[5,6]
  - Upper tract imaging with renal ultrasound is the standard for low and intermediate individuals given the overall low rate of malignancy detected in individuals with microscopic hematuria. Renal ultrasound is noninvasive, readily available, and carries no risk of ionizing radiation while demonstrating a high sensitivity for renal masses and hydronephrosis.
  - Upper tract imaging for high risk individuals should include advanced imaging with urography (CT with/without contrast is preferred with associated 3D rendering if requested). MR Urogram (MR Abdomen and Pelvis with/without contrast) can be performed if CT is contraindicated.
  - Individuals with severe renal dysfunction, dye allergy, or other reasons where both CT and MRI are contraindicated should undergo renal ultrasound or non-contrast CT paired with retrograde pyelography.
- Individuals with microhematuria with family history of renal cell carcinoma or known genetic renal tumor syndrome should undergo upper tract imaging (renal ultrasound, CT or MR Urography) regardless of risk category.[1,6]
- An individual with previous negative workup with persistent microscopic hematuria may undergo repeat upper tract imaging.[1,6]

Hematuria and Flank Pain (Suspicion for Renal/ureteral Stones) (AB-39.3)

AB.HH.0039.3.A

v1.0.2026

- CT Abdomen and Pelvis without contrast (CPT® 74176) OR CT Urogram (CPT® 74178)
  - Request for 3-D reconstruction (CPT® 76377 or CPT® 76375) to be performed with a CT Urogram is considered medically necessary.
  - US abdomen or retroperitoneum is medically necessary in lieu of CT for any of the above indications.

Evidence Discussion

- Individuals with flank pain presenting with either microscopic or gross hematuria should undergo advanced imaging with CT of the abdomen and pelvis.
  - The choice of contrast is at the discretion of the provider and may differ for individuals with previous history or high risk of nephrolithiasis and individuals with a higher risk of malignancy.
  - 3D reconstruction of CT Urography may be performed as requested.
  - Alternatively, the provider may request abdominal or retroperitoneal ultrasound in lieu of a CT initially.

Hydronephrosis of Unexplained or Indeterminate Cause (AB-39.4)

AB.HH.0039.4.A
v1.0.2026

- CT Urogram (CPT® 74178)
  - Requests for 3-D reconstruction (CPT® 76377 or CPT® 76375) to be performed with a CT Urogram is considered medically necessary.
  - US abdomen or retroperitoneum is medically necessary in lieu of a CT for any of the above indications.
- Retroperitoneal Ultrasound (CPT® 76770) is medically necessary every 6 to 12 months for the following:
  - uncomplicated hydronephrosis OR
  - neurogenic bladder OR
  - myelomeningocele (open spinal dysraphism) OR
  - spina bifida

Evidence Discussion

- A new diagnosis of hydronephrosis without a known cause should undergo further workup. Advanced imaging with CT Urography with 3D reconstruction may be performed if requested to evaluate the course of the urinary tract for obstruction.[7]
- Alternatively, the provider may request abdominal or retroperitoneal ultrasound in lieu of a CT initially.[7]
- Individuals with known chronic, uncomplicated hydronephrosis or individuals with neurogenic bladder (spina bifida or other neurologic conditions) may undergo surveillance imaging with retroperitoneal ultrasound every 6-12 months to monitor for progression or development of hydronephrosis to prevent renal deterioration.[7]

Pyelonephritis (AB-40.1)

AB.UT.0040.1.A

v1.0.2026

- CT Abdomen and Pelvis without and with contrast (CPT® 74178) or CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary if:
  - suspected complicated: diabetes, immunocompromised, history of stones, prior renal surgery, or fever ≥101 F (≥38.5 C) OR
  - not responding to therapy after 3 days OR
  - recurrent pyelonephritis (at least 1 prior pyelonephritis) OR
  - males with first time UTI or recurrent UTI without etiology

  Note:

  3-D Reconstruction enhances a CT Urogram (CPT® 74178).

  Requests for 3-D reconstruction (CPT® 76377 or 76376) for a CT Urogram can be considered medically necessary.

- MRI Abdomen without or with and without contrast (CPT® 74181 or CPT® 74183) is medically necessary if:
  - Elevated creatinine
- Pregnant individuals should be evaluated initially by renal ultrasound (CPT® 76770 or CPT® 76775) and if further imaging is medically necessary, MRI Abdomen and Pelvis without contrast (CPT® 74181 and CPT® 72195).

Evidence Discussion

- Pyelonephritis is a clinical diagnosis and advanced imaging is often not beneficial according to guidance from the American College of Radiology and the American Urological Association, as a majority of individuals will clinically improve with appropriate antibiotic therapy.[1,9,10]
- Advanced imaging may be medically necessary with contrasted CT (urography if requested) in individuals with complicated clinical pictures which may include immunocompromised individuals or those with diabetes mellitus, history of nephrolithiasis, prior renal surgery, or those with fever. All males with urinary tract infection are considered to have a complicated urinary tract infection and thus advanced imaging may be considered medically necessary[1,9,10]
- Alternative imaging with MRI of the abdomen and pelvis with and without contrast may be medically necessary if renal dysfunction is present.[1,9,10]
- If an individual is unresponsive to therapy after 3 days, or if there is at least one prior episode of pyelonephritis, advanced imaging may be medically necessary. [1,9,10]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Pregnant individuals are considered high risk for complications from pyelonephritis, however first line imaging should be with renal ultrasound to avoid ionizing radiation exposure. If further imaging is felt medically necessary, MRI of the abdomen and pelvis without contrast may be performed.[1,3,9,10]

Lower Urinary Tract Infection (AB-40.2)

AB.UT.0040.2.A

v1.0.2026

- CT Abdomen and Pelvis without and with contrast (CPT® 74178) is medically necessary if:
  - suspected complicated: diabetes,immunocompromised,history of stones, prior renal surgery, or fever ≥101 F (≥38.5 C) OR
  - not responding to therapy after 3 days OR
  - males with first time UTI or recurrent UTI without etiology OR
  - recurrent UTI ≥3 per year OR
  - recommendation by or in consultation with a urologist or specialist

  Note: 3-D Reconstruction enhances a CT Urogram (CPT® 74178). Requests for 3-D reconstruction (CPT® 76377 or 76376) for a CT Urogram can be considered medically necessary.
- MRI Abdomen and MRI Pelvis without or with and without contrast (CPT® 74181 and CPT® 72195 or CPT® 74183 and CPT® 72197) is medically necessary if requested when ALL of the following apply:
  - Criteria (as above) for CT Abdomen and Pelvis without and with contrast are met, AND
  - Elevated creatinine
- See: **Periurethral Cysts and Urethral Diverticula (PV-13)** in the Pelvis Imaging Guidelines

Evidence Discussion

- Advanced imaging for a lower urinary tract infection is not beneficial in most clinical scenarios according to guidance from the American College of Radiology and the American Urological Association, as few individuals with cystitis will progress to an upper urinary tract infection.[1,2,8,9]
- CT of the abdomen and pelvis with and without contrast may be medically necessary in the context of a complicated urinary tract infection, recurrent urinary tract infections (greater than 3 episodes in one year), or if recommended by a urologist or specialist.[1,2,8,9]
- Complicated urinary tract infections may include immunocompromised individuals or those with diabetes mellitus, history of nephrolithiasis, prior renal surgery, or those with fever. All males with urinary tract infection are considered to have a complicated urinary tract infection and thus advanced imaging may be considered medically necessary[1,2,8,9]

Liver Transplant, Pre-Transplant (AB-42.1)

AB.TX.0042.1.A
v1.0.2026

- Individuals **WITHOUT hepatocellular carcinoma (HCC)** referred to a transplant center for liver transplant evaluation can undergo advanced imaging as follows:
  - Per the transplant institution's protocol, OR
  - Per the studies and intervals listed below:

Imaging Study	Interval	Comments
Both of the following US studies: ◦ Abdominal US (CPT® 76700 or CPT® 76705) and ◦ Doppler (CPT® 93975)	◦ Every 6 months	
ONE of the following abdomen/pelvis advanced imaging studies: ◦ CT Abdomen (CPT® 74160 or CPT® 74170) ◦ MRI Abdomen (CPT® 74183)	◦ Annually ▪ Individuals with known cholangiocarcinoma may have more frequent repeat of studies at left per institution's protocol	
Additional abdomen/ pelvis advanced imaging, for individuals on the transplant list with known Primary Sclerosing Cholangitis (PSC): ◦ MRCP (See: **MRCP (AB-27.1)** for acceptable CPT® codes)	◦ Per the transplant institution's protocol	

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Imaging Study	Interval	Comments
◦ CT Chest with or without contrast (CPT® 71260 or CPT® 71250)	◦ One-time ▪ Individuals with known cholangiocarcinoma may have more frequent repeat of studies at left per institution's protocol	◦ Repeat studies based on clinical indications per **Chest Imaging Guidelines**
ONE of the following: ◦ MRI Bone Marrow Blood Supply (CPT® 77084) or ◦ Bone scan (CPT® 78306)	◦ One-time	
Echocardiography with ONE of the following: ◦ CPT® 93306 (preferred) ◦ CPT® 93307 ◦ CPT® 93308	◦ Annually	See: **Cardiac Imaging in Transplant CD-16** for descriptions of CPT codes or further indications
CT Coronary angiography (CCTA) (CPT® 75574)	◦ Annually	See: **Cardiac Imaging in Transplant CD-16** for descriptions of CPT codes or further indications
Stress imaging in place of but not in addition to CT Coronary angiography (CCTA) - ONE of the following: ◦ CPT® 93350 ◦ CPT® 93351 ◦ CPT® 78452 ◦ CPT® 75563 ◦ CPT® 78492 ◦ CPT® 78431	◦ Annually	See: **Cardiac Imaging in Transplant CD-16** for descriptions of CPT codes or further indications

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Imaging Study	Interval	Comments
For individuals with systemic amyloidosis: ◦ Cardiac MRI – ONE of the following: ▪ CPT® 75557 ▪ CPT® 75561 ◦ If Cardiac MRI is contraindicated or indeterminate, ONE of the following SPECT studies may be performed: ▪ CPT® 78803 ▪ CPT® 78830	◦ One-time	See: **Cardiac Imaging in Transplant CD-16** for descriptions of CPT codes or further indications
If required to further assess CAD seen on a recent CCTA that is of uncertain physiologic significance, CT-FFR (Noninvasive estimated coronary fractional flow reserve derived from coronary computed tomography angiography) with ONE of the following: ◦ CPT® 0501T ◦ CPT® 75580	◦ One-time	See: **Cardiac Imaging in Transplants CD-16** for descriptions of CPT codes or further indications

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Imaging Study	Interval	Comments
In place of CT Coronary angiography or stress imaging for initial pre-transplant evaluation, OR If CT Coronary angiography and/or CT-FFR or stress imaging is abnormal WITH addition of right heart catheterization if requested for evaluation of pulmonary hypertension: ◦ Left heart catheterization or left and right heart catheterization with ONE of the following: ▪ CPT® 93458 ▪ CPT® 93454 ▪ CPT® 93460 ▪ CPT® 93456 ◦ Or if prior CABG, with ONE of the following: ▪ CPT® 93459 ▪ CPT® 93455 ▪ CPT® 93461 ▪ CPT® 93457	◦ One-time	Repeat studies as per **Cardiac Imaging in Transplant CD-16**
ONE of the following, for vascular evaluation in anticipation of transplant: ◦ CTA (CPT® 74175) ◦ MRA Abdomen (CPT® 74185)	◦ One-time	

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Imaging Study	Interval	Comments
ANY of the following may be performed immediately prior to transplant: ◦ Abdominal US (CPT® 76700 or CPT® 76705) AND Doppler (CPT® 93975) ◦ CT Abdomen (CPT® 74160 or CPT® 74170) OR MRI Abdomen (CPT® 74183) ◦ CT Abdomen and Pelvis (CPT® 74177) or CT Pelvis (CPT® 72193) ◦ CTA (CPT® 74175) OR MRA Abdomen (CPT® 74185)	◦ Once, immediately prior to transplant	

- Individuals **WITH hepatocellular carcinoma (HCC)** referred to a transplant center for liver transplant evaluation can undergo advanced imaging as follows:
  - Per the transplant institution's protocol, OR
  - Per the studies and intervals listed below:

Imaging Study	Interval	Comments
Both of the following US studies: ◦ Abdominal US (CPT® 76700 or CPT® 76705) and ◦ Doppler (CPT® 93975)	◦ Every 6 months

Liver Transplant, Living Donor Pre-Transplant Imaging (Donor Imaging) (AB-42.2)

AB.TX.0042.2.A

v1.0.2026

- CT Abdomen with contrast (CPT® 74160) OR CT Abdomen without and with contrast (CPT® 74170) OR MRI Abdomen without and with contrast (CPT® 74183) is medically necessary to assess liver anatomy and volumetrics.
- MRCP is medically necessary to assess biliary anatomy (See: **MRCP (AB-27.1)** for proper coding)
- CTA Abdomen without and with contrast (CPT® 74175) OR MRA Abdomen without and with contrast (CPT® 74185) is medically necessary to assess vascular anatomy.
- For donor imaging post-transplant, imaging is medically necessary per transplant center protocol. If no transplant center protocol exists, see condition-specific guideline appropriate to the individual's signs and symptoms.

Evidence Discussion

Living donor liver transplantation (LDLT) has become a widely accepted solution to alleviate the ongoing shortage of cadaveric livers for deceased donor liver transplantation (DDLT). Radiologic evaluation plays a crucial role in assessing both donor candidates and recipients to confirm their eligibility and determine the most suitable surgical approach.[54]

A comprehensive pre-operative assessment of the vascular, liver volume, and biliary anatomy is vital for the safe and successful harvesting, transplantation, and long-term success of the graft. Computed tomography (CT) and magnetic resonance imaging (MRI) are the preferred imaging techniques for this purpose. These cross-sectional methods offer detailed views of the vascular and biliary structures, assess the hepatic parenchyma, and enable volumetric analysis.[16,55]

LDLT evaluation typically combine MRI/MRCP and CT to leverage the higher spatial resolution of CT for arterial evaluation and the superior soft tissue, parenchymal and biliary analysis provided by MRI. Besides examining the liver parenchyma for abnormalities such as steatosis, a detailed evaluation of the hepatic volume, vascular and biliary system for significant anatomic variants is essential, as these variants can influence surgical techniques and outcomes for both recipients and donors.[56]

Liver Transplant, Post-Transplant Imaging (AB-42.3)

AB.TX.0042.3.A
v1.0.2026

- Cardiac Imaging:
  - See: **Cardiac Imaging in Transplants CD-16** in the Cardiac Imaging Guidelines
- Suspected post-operative complications:
  - Vascular thrombosis (suspected hepatic artery thrombosis) imaging is medically necessary as follows:
    - Doppler ultrasound (CPT® 93975)
    - CTA Abdomen without and with contrast (CPT® 74175) OR MRA Abdomen without and with contrast (CPT® 74185)
  - Suspicion of biliary anastomotic strictures:
    - MRCP (See: **MRCP (AB-27.1)** for appropriate CPT codes)
    - Vascular imaging as above for vascular thrombosis may also be requested and considered medically necessary for this indication
  - Other suspected post-operative complications (e.g., infection, etc.)
    - Imaging as requested by the transplant institution or team
- Transplant individuals without prior HCC or cholangiocarcinoma:
  - Routine post-transplant imaging is not medically necessary.
  - If cirrhosis develops post-transplant:
    - See: **Cirrhosis and Liver Screening for Hepatocellular Carcinoma (HCC) (AB-26.1)**, **Ascites (AB-26.2)**, and **Portal Hypertension (AB-26.3)** for HCC screening guidelines.
  - Fibrosis assessment post-liver transplant:
    - Transient elastography (CPT® 91200) is medically necessary, which is the most studied modality in this setting.
- Surveillance after transplant for HCC is medically necessary as follows:
  - Based on RETREAT score
    - 0 points: No additional screening needed
    - 1-3 points: CT or MRI Abdomen (CPT® 74160, or CPT® 74170, or CPT® 74183) and CT Chest (CPT® 71260 or CPT® 71250) every 6 months for 2 years.
    - 4 points: CT or MRI Abdomen (CPT® 74160, or CPT® 74170, or CPT® 74183) and CT Chest (CPT® 71260 or CPT® 71250) every 6 months for 5 years
    - ≥5 points: CT or MRI Abdomen (CPT® 74160, or CPT® 74170, or CPT® 74183) and CT Chest (CPT® 71260 or CPT® 71250) every 3 months for 2 years, then every 6 months between the 2nd and 5th years.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- If there is a suspicion of recurrent tumor based on clinical findings and/or sequentially increasing AFP:
  - CT Abdomen (CPT® 74160 or CPT® 74170) or MRI Abdomen (CPT® 74183) is medically necessary
- Imaging after transplant for primary sclerosing cholangitis (PSC):
  - Suspected recurrence of PSC;
    - MRCP (See: **MRCP (AB-27.1)** for proper coding)
- Imaging after transplant for cholangiocarcinoma is medically necessary as follows:
  - Liver ultrasound (CPT® 76705 or CPT® 76700) or MRI Abdomen and MRCP (CPT® 74183) every 6 months for 5 years post-transplantation.
  - CT Chest (CPT® 71250 or CPT® 71260) every 6 months for 5 years post-transplantation

Background and Supporting Information

Consensus guidelines regarding post-transplant surveillance imaging have not yet been established. There have been recent attempts to establish evidence-based guidelines, including the development of the RETREAT score, validated recently in a study conducted at University of California, San Francisco, Mayo Clinic-Rochester, and Mayo Clinic-Jacksonville. This scoring system has been adopted for use by UCSF and guides post-transplant imaging for individuals who have undergone transplant for HCC.

The RETREAT score is a protocol used to estimate the risk of tumor recurrence after liver transplantation in individuals who have been transplanted for the treatment of hepatocellular carcinoma. It is comprised of three factors which are assessed before and after transplant. Points are assigned based on criteria which include the alpha-fetoprotein level before liver transplantation, the presence or absence of microvascular invasion, and the sum of the diameter of the largest viable tumor and the number of viable nodules on pathologic examination of the explant liver.

The RETREAT score is obtained by adding the total number of points scored in each of the 3 variables (range 0-8). For example: RETREAT score=0 if the individual has AFP 0-20 ng/mL at LT, no vascular invasion and no viable tumor in the explant.

The RETREAT score is calculated as follows:

Risk Factor	Score
Alpha-fetoprotein level before LT	
0-20	0
21-99	1

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Risk Factor	Score
100-999	2
≥1000	3
Microvascular invasion present	2
Sum of the diameter of the largest viable tumor and the number of viable nodules	
0	0
1.1-4.9	1
5.0-9.9	2
≥10	3

Evidence Discussion

Clinical manifestations of liver transplant complications can be subtle and non-specific and medical imaging plays an important role. Often, a rise in liver enzymes is the earliest sign of graft problems, allowing for timely clinical intervention to protect allograft function.[20-22,24-30,32,33]

Throughout the lifetime of a post liver transplant individual, complications affecting the liver allograft could be caused by vascular and biliary complications, immune-mediated injury, drug-related issues, infectious complications, and recurrence of the primary liver disease.[20-22,24-30,32,33]

Thus, managing these individuals depends on a thorough clinical history, symptoms, laboratory data, and imaging studies; at times multiple imaging modalities are required.

There is no specific consensus of what type, or when a post liver transplant individual will need or require an imaging test and it typically depends on post liver transplant imaging protocols specific to a transplant centre, or abnormal laboratory tests.[20-22,24-30,32,33]

However, as standard practice, ultrasound sonography plus colour-Doppler ultrasound examination is routinely performed at 24–48 h, on the 7th day and 21st day (Mayo Clinic protocol), and on the first and third month after transplantation to evaluate the

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

liver parenchyma and vascular structures integrity. The frequency and indication vary between transplant centres, and post-transplant protocols.[20-22,24-30,32,33]

In addition, testing is performed anytime there is an unexpected change in liver enzymes potentially including additional testing such as CT imaging and MR imaging techniques, including contrast-enhanced CT or MR angiography and MR cholangiography to further evaluate the transplanted liver. These tests can reveal abnormalities in vascular structures, bile ducts, liver parenchyma, and extrahepatic tissues.[20-22,24-30,32-33]

In the case of a history of pre-liver transplant hepatocellular carcinoma (HCC), even with adherence to Milan criteria, HCC recurs post-LT in 10%–15% and is the most common cause of death in this population. [20-22,24-30,32,33]

A multicenter analysis has proposed and validated a risk stratification score, Risk Estimation of Tumor Recurrence After Transplant (RETREAT), which incorporates AFP at LT, vascular invasion, the sum of the largest viable tumor diameter, and number of viable tumors on explant.[20-22,24-30,32,33]

RETREAT stratifies 5-year recurrence risk from <3% in individuals without viable tumor on explant or microvascular invasion and AFP <20ng/ml (i.e., RETREAT 0) up to 75% in the highest-risk individuals (RETREAT≥5).[6]

In this population, because the two most common sites of post-transplant recurrence are the lung (~40%) followed by the liver (33%), surveillance is advised. The AASLD advises surveillance for detection of post-transplant HCC recurrence using multiphasic contrast-enhanced abdominal CT or MRI and chest CT scan. The optimal timing and duration of post-transplant surveillance is uncertain; however, risk scores may be considered to guide decisions. [20-22,24-30,32,33]

Beyond allograft-related complications, metabolic syndrome, cardiovascular disease, renal dysfunction, and malignancies are leading causes of morbidity and mortality in this individual population. These individuals will require cardiovascular evaluation, breast cancer, and lung cancer surveillance per individual risk and transplant centre expert team recommendations as some individuals could carry a slightly higher risk than the non-transplant population.[20-22,24-30,32,33]

Post-Transplant Lymphoproliferative Disorder (PTLD) (AB-42.4)

AB.TX.0042.4.A

v1.0.2026

- CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary for known or suspected PTLD.
- Additional evaluation of suspected PTLD is the same as the evaluation of lymphoma. See: **Post-Transplant Lymphoproliferative Disorders (ONC-27.9)** in the Oncology Imaging Guidelines for further recommendations
- Routine use of imaging to screen for PTLD is not medically necessary as there is insufficient supporting evidence.

Background and Supporting Information

- Post-transplant lymphoproliferative disease (PTLD) is a major complication of solid organ transplantation and the spectrum ranges from benign hyperplasia to malignant lymphoma. It has an incidence of 1-20%, and is usually related to Epstein-Barr virus infection in the setting of immunosuppression.

Evidence Discussion

For suspected PTLD advanced imaging studies are extremely helpful. CT Chest/ Abdomen/Pelvis with contrast are the mainstay for known or suspected PTLD. PTLD generally is rapid growing and small ill-defined masses of lymphoid tissue cannot be initially identified on sonography. Since PTLD has the potential of being reversed by decreasing immunosuppression, early detection with more advanced imaging can very beneficial.[37]

Kidney Transplant, Pre-Transplant Imaging Studies (AB-42.5)

AB.TX.0042.5.A
v1.0.2026

Pre-Transplant Evaluation (Per Institution Protocol)

- Individuals referred to a transplant center for kidney or kidney-pancreas transplant evaluation can undergo advanced imaging as follows:
  - Per the transplant institution's protocol, OR
  - Per the studies and intervals listed below:

Imaging Study	Interval	Comments
ONE of the following abdomen/pelvis imaging studies is medically necessary: • CT Abdomen and Pelvis without contrast (CPT® 74176) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CTA Abdomen without and with (CPT® 74175) • CTA Abdomen and Pelvis (CPT® 74174) • CTA Pelvis without and with (CPT® 72191)	One-time	
ONE of the following echocardiography studies is medically necessary: • CPT® 93306 (preferred) • CPT® 93307 • CPT® 93308	Annual	See also: **Cardiac Imaging in Transplant CD-16** for descriptions of CPT codes or further indications
ONE of the following stress imaging studies is medically necessary: • CPT® 93350 • CPT® 93351 • CPT® 78452 • CPT® 75563 • CPT® 78492 • CPT® 78431	Annual	See also: **Cardiac Imaging in Transplant CD-16** for descriptions of CPT codes or further indications

Proprietary Information of UnitedHealthcare.

Additional Pre-Transplant Evaluation (Per Indication)

Individuals referred to a transplant center for kidney or kidney-pancreas transplant evaluation can undergo the following additional advanced imaging when the listed indications are met:

Indication	Imaging Study	Interval	Comments
• 20 pack-year history of smoking	ONE of the following is medically necessary: • CT Chest without contrast (CPT® 71250) • CT Chest with contrast (CPT® 71260)	One-time	For lung cancer screening with Low Dose Computed Tomography (LDCT), see: **U.S. Preventative Services Task Force: Lung Cancer Screening (Commercial and Medicaid) (CH-33.1)**
• Autosomal dominant polycystic kidney disease	ONE of the following is medically necessary: • MRA Head (CPT® 70544, 70545, or 70546) • CTA Head (CPT® 70496)	One-time	Repeat imaging as per **Intracranial Aneurysms (HD-12.1)**
• History of stroke, or • History of TIA, or • Carotid bruit on exam	ONE of the following is medically necessary: • Carotid duplex bilateral study (CPT® 93880 or CPT® 73882)	One-time	Repeat imaging as per **Initial Imaging (PVD-3.1)**
• Presence of systemic amyloidosis	ONE of the following cardiac MRI studies is medically necessary: • CPT® 75557 • CPT® 75561	One-time	See also: **Cardiac Imaging in Transplant CD-16** for descriptions of CPT codes or further indications

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Indication	Imaging Study	Interval	Comments
BOTH of the following: • Presence of systemic amyloidosis AND • Cardiac MRI is either contraindicated or indeterminate	ONE of the following nuclear medicine studies is medically necessary: • CPT® 78803 • CPT® 78830	One-time	See also: **Cardiac Imaging in Transplant CD-16** for descriptions of CPT codes or further indications
• In place of stress imaging for initial pre-transplant evaluation, or • Stress imaging is positive for ischemia	ONE of the following heart catheterization is medically necessary: • CPT® 93458 • CPT® 93454 • If prior CABG: ◦ CPT® 93459 ◦ CPT® 93455	One-time	Repeat imaging as per **Cardiac Imaging in Transplant CD-16**

Kidney Donor Nephrectomy or Pre-Transplant Nephrectomy

Indication	Imaging Study	Comments
• Individuals being evaluated for living kidney donation, or • Individual is planning removal of one or both kidneys	ONE of the following is medically necessary: • CTA Abdomen (CPT® 74175) • MRA Abdomen (CPT® 74185) • MRI Abdomen without and with contrast (CPT® 74183)	For CTA and MRA, 3D rendering is included with the original study

Evidence Discussion

Individuals being assessed for kidney or kidney-pancreas transplant require advanced imaging of the abdomen and/or pelvis either with or without contrast (to include angiography). This allows assessment of any intra-abdominal pathology, which may complicate transplantation. MR angiography may be indicated for assessment of the

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

native kidneys when considering pre-transplant nephrectomy. Individuals may also be assessed according to the standardized imaging protocol of the transplant center.[14-18]

Although there is some debate regarding coronary artery disease (CAD) screening and transplant outcomes, a preoperative cardiac workup is essential for prognostication given the significant association with chronic kidney disease (CKD) and CAD. This may include a transthoracic echocardiogram as well as a stress echocardiogram and/or cardiac catheterization.[14-18]

Cardiac MRI can be performed in individuals with systemic amyloidosis, as cardiac involvement is the leading cause of morbidity and mortality. If the MRI is indeterminate or contraindicated, myocardial Tc-99m pyrophosphate imaging may be performed.[14-18]

Individuals with an extensive smoking history of greater than 20 pack-years may undergo CT of the chest (either with or without contrast), which is guided by evidence of the National Lung Screening Trial to reduce risk of mortality.[14-18]

Any individual with a history of transient ischemic attack (TIA) or stroke may undergo a carotid duplex study for preoperative assessment. Individuals with autosomal dominant polycystic kidney disease (ADPKD) may undergo MR or CT angiography of the head to screen for aneurysms.[14-18]

Individuals being assessed for kidney donation should have advanced abdominal imaging with CT or MR angiography to assess kidney size and vasculature.[14-18]

Kidney Transplant, Post-Transplant (AB-42.6)

AB.TX.0042.6.A
v1.0.2026

- Ultrasound of transplanted kidney:
  - Current ultrasound imaging protocols of the transplanted kidney commonly include a Doppler study and are coded as CPT® 76776.
    - Do not report non-invasive vascular codes CPT® 93975 and CPT® 93976 in conjunction with CPT® 76776.
  - Ultrasound of the transplanted kidney performed without duplex Doppler should be reported as a limited retroperitoneal ultrasound (CPT® 76775).

Evidence Discussion

- Imaging evaluation of the transplanted kidney may be necessary for routine surveillance or to allow for early diagnosis of post-transplant complications or graft dysfunction.[14-18]
- The preferred initial imaging is duplex ultrasound with Doppler as this provides readily-available, reliable imaging which is non-invasive and does not require the use of ionizing radiation nor intravenous contrast.[14-18]

Hepatic Arteries and Veins (AB-43.1)

AB.HA.0043.1.A
v1.0.2026

- Portal Vein Thrombosis (PVT):
  - Doppler US (CPT® 93975) is the initial noninvasive modality for the diagnosis of Portal Vein Thrombosis
  - CT Abdomen with contrast (CPT® 74160 or 74170 – 4 phase CT), MRI Abdomen without and with contrast (CPT® 74183) or CTA Abdomen (CPT® 74175) is medically necessary for ANY of the following:
    - to assess the extension of thrombus into the mesenteric veins when Doppler US (or other imaging, such as abdominal US) is positive for PVT
    - to exclude tumor thrombus among individuals with cirrhosis who develop new portal and/or mesenteric vein thrombosis
    - for continued concern for PVT (for example in an individual with a hypercoagulable state or abdominal malignancy) if Doppler US is negative or inconclusive
  - To assess for development of intestinal ischemia among individuals with known portal and/or mesenteric vein thrombosis (MVT) (e.g., development of fever, rebound, leukocytosis, elevated serum lactate levels):
    - In lieu of the above imaging modalities, if requested: CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary.
  - For suspicion of portal hypertensive or portal cavernoma cholangiopathy in individuals with known PVT or MVT (cholestatic liver chemistry profile (See **Abnormal Liver Chemistries (AB-30.1)**), known portal cavernoma, extrahepatic biliary abnormalities on imaging):
    - MRCP (CPT® 74183 or CPT® 74181) is medically necessary

Note: Portosystemic collaterals in the region surrounding the common bile duct in individuals with chronic PVT can be associated with common bile duct obstruction.

- For routine follow-up of PVT:
  - US/Doppler every 6 months. If these are reported as not providing adequate visualization, CT Abdomen (CPT® 74160), MRI Abdomen (CPT® 74183), or CTA Abdomen (CPT® 74175), is medically necessary.
- For follow-up of PVT being treated with anticoagulation:
  - US/Doppler, CT Abdomen (CPT® 74160), MRI Abdomen (CPT® 74183), or CTA Abdomen (CPT® 74175) is medically necessary in 3-6 months.
  - Further follow-up every 6 months with US/Doppler unless these are reported as not providing adequate visualization, in which case any of the above studies can be approved.

Proprietary Information of UnitedHealthcare.

- TIPS (transjugular intrahepatic portosystemic shunt)
  - Pre-procedure evaluation:
    - Abdominal US, including Doppler (CPT® 76700 and/or CPT® 93975), Multiphase CT Abdomen (CPT® 74160 or CPT® 74170), Multiphase CTA Abdomen (CPT® 74175), Multiphase MRA Abdomen (CPT® 74185), or MRI Abdomen liver protocol (CPT® 74183) is medically necessary
    - Echocardiogram (CPT® 93306) (see: **Transthoracic Echocardiography (TTE) – Indications/Initial Evaluation (CD-2.2)**)
  - For routine follow-up to monitor stent patency:
    - US with Doppler (CPT® 93975) is medically necessary 7-14 days after shunt creation, and then at 3 months, 6 months, and then every 6 months thereafter.
      - If requested earlier than the above intervals because of a clinical deterioration or suspicion of stent occlusion, the Doppler is medically necessary.
  - If Doppler imaging is indeterminate or if there is a negative Doppler with clinical signs of worsening portal hypertension the following is medically necessary:
    - Multiphase CT Abdomen (CPT® 74160 or CPT® 74170), Multiphase CTA Abdomen (CPT® 74175), Multiphase MRA Abdomen (CPT® 74185), or MRI Abdomen liver protocol (CPT® 74183)
  - Echocardiogram (CPT® 93306) is medically necessary for the following:
    - One time post-procedure for routine follow up
    - Any time post-procedure:
      - for new signs or symptoms
      - for concern for new or worsening pulmonary hypertension
      - See also: **Frequency of Echocardiography Testing (CD-2.3)** in the Cardiac Imaging Guidelines
- For the evaluation of Budd-Chiari Syndrome
  - Doppler US (CPT® 93975) is the initial diagnostic test for the evaluation of BCS.
  - CT Abdomen with contrast (CPT® 74160), or MRI Abdomen without and with contrast (CPT® 74183) or CTA Abdomen (CPT® 74175) is medically necessary for ANY of the following:
    - to assess thrombus extension
    - to rule out tumor thrombus
    - to assess response to anticoagulation therapy
    - if there is high suspicion of BCS despite a negative or inconclusive Doppler US
    - to additionally assess indeterminate hepatic nodules detected on the prior US (any of the above studies or CT Abdomen without and with contrast CPT® 74170)
  - For pre-operative evaluation of anticipated interventional vascular therapies or TIPS the following is medically necessary:

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

        - Abdominal US, including Doppler (CPT® 76700 and/or CPT® 93975), Multiphase CT Abdomen (CPT® 74160 or CPT® 74170), Multiphase CTA Abdomen (CPT® 74175), Multiphase MRA Abdomen (CPT® 74185), or MRI Abdomen liver protocol (CPT® 74183)
    - For HCC Surveillance in individuals with chronic BCS the following is medically necessary:
        - Abdominal US (CPT® 76700 or CPT® 76705) and serum alpha-fetoprotein every 6 months
        - Triphasic CT Abdomen (CPT® 74160 or CPT® 74170), or MRI Abdomen (CPT® 74183) for the evaluation of hepatic nodules seen on US or AFP ≥15 ng/ml.
        - The LiRADS reporting system does not apply to HCC surveillance in this population, due to the vascular origin of many of the hepatic imaging abnormalities.
- Hereditary Hemorrhagic Telangiectasia (HHT)
    - The liver may be involved in individuals with HHT, and artery-to-vein or vein-to-vein shunting may occur resulting in liver vascular malformations (LVMs).
    - Screening the liver for LVMs is not medically necessary.
    - For symptoms suggestive of liver vascular malformations (LVMs) (including an audible bruit or palpable thrill over the hepatic region on physical examination, abnormal liver tests) or for the development of signs or symptoms of heart failure, biliary ischemia, hepatic encephalopathy, mesenteric ischemia, or portal hypertension the following is medically necessary:
        - CT Abdomen (CPT® 74160), CTA Abdomen (CPT® 74175), MRI Abdomen with and without (CPT® 74183), MRCP (CPT® 74183), or MRA Abdomen (CPT® 74185)
- CTA Abdomen and Pelvis (CPT® 74174), or CTA Abdomen (CPT® 74175) or MRA Abdomen (CPT® 74185) is medically necessary additionally for:
    - Evaluation of portal and hepatic veins prior to or following surgical intervention for the treatment of portal hypertension (See: **Portal Hypertension (AB-26.3)**)
    - Evaluation of hepatic vasculature prior to and following embolization procedure (See: **Hepatocellular Carcinoma (HCC) – Restaging/Recurrence (ONC-14.4)** and **Hepatocellular Carcinoma (HCC) – Surveillance/Follow-up (ONC-14.5)** and **Liver Metastases (ONC-31.2)** in the Oncology Imaging Guideline)
    - Evaluation of hepatic vasculature prior to planned hepatectomy (See: **Liver Transplant, Pre-Transplant (AB-42.1)**)
    - Evaluation of liver donor (See: Liver Transplant, **Living Donor Pre-Transplant Imaging (Donor Imaging) (AB-42.2)** for specific guidance)
- Hepatic arterial aneurysms:
    - See: **Visceral Artery Aneurysm (PVD-6.5)** in the Peripheral Vascular Disease Imaging Guidelines

Background and Supporting Information

Primary Budd-Chiari Syndrome is due to thrombotic occlusion of the hepatic venous outflow tract. Most individuals have an underlying prothrombotic condition such as a myeloproliferative disease, an inherited thrombophilia (e.g. Factor V Leiden), a systemic disease such as vasculitis, or hormonal factors, such as recent oral contraceptive use. Secondary Budd-Chiari Syndrome is caused by malignant tumors or extrinsic compression of the hepatic veins.

LI-RADS assessment should not be applied to individuals <18 years old or those with cirrhosis from congenital hepatic fibrosis secondary to vascular disorders (e.g, Budd-Chiari syndrome, chronic portal vein occlusion, cardiac congestion, hereditary hemorrhagic telangiectasia).

Evidence Discussion

- In cases of Primary Budd-Chiari syndrome, Doppler ultrasound is widely used to evaluate hepatic/portal vasculature. Ultrasonographic evaluation is associated with advantages such as high sensitivity and specificity, and also high positive and negative predictive values.[5]
- Advantages of Doppler ultrasound include low cost, wide availability, and lack of radiation exposure.[5]
- One disadvantage of Doppler ultrasound is its limited ability to evaluate certain anatomies. For instance, it may not be able to detect the extension of portal vein thrombus into splanchnic vessels.[5]
- CT scan is highly accurate in evaluating hepatic vasculature, with sensitivity, specificity, PPV and NPV in the range of 90-99%.[5]
- Advantages of CT scan include better visualization of structures, such as thrombus extension. Another advantage of CT is that it allows for concomitant evaluation of bowel.[5]
- CT scan has drawbacks such as higher cost, radiation exposure, and potential complications from the use of contrast, when compared to ultrasound.[5]
- MRI and MRA may be more appropriate as alternative to CT. Advantages include lack of radiation and a "better safety profile." Disadvantages include longer image acquisition time, higher cost, and various technical limitations., including signal loss, overestimation of stenoses, and contraindications/complications related to implanted metallic devices.[5]
- Pre-TIPS (Transjugular Intrahepatic Portosystemic Shunt), endovascular variceal obliteration or embolization, should ideally include cross-sectional imaging to have an adequate anatomical map of the portal vein and hepatic veins.[17]
- Screening the liver for LVMs is not medically necessary. As per recent ACG Guidelines, "there is no evidence to suggest that making a diagnosis in an asymptomatic individual has clinical benefits or prevents death.[5]

Abdominal Veins Other than Hepatic and Portal Veins (AB-43.2)

AB.HA.0043.2.A

v1.0.2026

- CTA Abdomen and Pelvis (CPT® 74174), or CTA Abdomen (CPT® 74175) or MRA Abdomen (CPT® 74185) is medically necessary if ONE of the following:
  - Nephrotic syndrome
  - Renal vein thrombosis
  - Mesenteric vein thrombosis
- Suspicion of iliac vein thrombus when a lower extremity duplex or abdominal duplex is inconclusive or equivocal, see: **Acute Deep Venous Thrombosis (DVT) (PVD 12.2)**
- Suspicion of inferior vena cava thrombus when a lower extremity duplex or abdominal duplex is inconclusive or equivocal, see: **Acute Deep Venous Thrombosis (DVT) (PVD 12.2)**

Evidence Discussion

- Computed Tomography Angiography (CTA) is a diagnostic imaging test that can assess both arterial and venous structures, as well as nonvascular structures in cases of venous thrombosis.[18,19] By combining the evaluation of both vascular and nonvascular findings, it is possible to achieve a sensitivity of 96% and a specificity of 90-94% when assessing for mesenteric venous obstruction.[18]
- In cases of chronic mesenteric venous thrombosis, duplex ultrasound can be a helpful tool for diagnosis. However, due to potential technical difficulties such as overlying bowel gas or limited acoustic windows, imaging may not always be possible.[18,19] In such cases, a CTA scan may be a better option as it allows for a more comprehensive evaluation of both vascular and intestinal structures.[18]
- Contrast-enhanced Magnetic Resonance Angiography (MRA) has been shown to provide a vascular assessment that is comparable to catheter angiography.[1]
- Compared to catheter angiography, MRA is less invasive, cheaper, and does not expose individuals to ionizing radiation.[1]
- Various MRA techniques allow for quantification of blood flow as well as evaluation of oxygen saturation, which are not possible with CTA.[1]
- MRA is less dependent on the operator compared to vascular ultrasound and is less prone to limitations related to individual body habitus or overlying bowel gas.[1]
- Disadvantages of MRA are motion artifact and risk of nephrogenic systemic fibrosis with gadolinium exposure in individuals with severe renal insufficiency.[1]

Renal Vein Thrombosis (AB-43.3)

AB.HA.0043.3.A

v1.0.2026

- MRA Abdomen (CPT® 74185) is medically necessary if ONE of the following:
  - Nephrotic syndrome
  - Proteinuria – 3 grams or more in 24 hours
  - Lupus nephritis
  - Hypercoagulable state, ONE of the following:
    - Antiphospholipid antibodies
    - Behçet's syndrome
    - Protein C deficiency
    - Protein S deficiency

Evidence Discussion

- Computed Tomography Angiography (CTA) is a diagnostic imaging test that can assess both arterial and venous structures, as well as nonvascular structures in cases of venous thrombosis.[18,19] By combining the evaluation of both vascular and nonvascular findings, it is possible to achieve a sensitivity of 96% and a specificity of 90-94% when assessing for mesenteric venous obstruction[18]
- In cases of chronic mesenteric venous thrombosis, duplex ultrasound can be a helpful tool for diagnosis. However, due to potential technical difficulties such as overlying bowel gas or limited acoustic windows, imaging may not always be possible.[18,19] In such cases, a CTA scan may be a better option as it allows for a more comprehensive evaluation of both vascular and intestinal structures.[18]
- Contrast-enhanced Magnetic Resonance Angiography (MRA) has been shown to provide a vascular assessment that is comparable to catheter angiography.[1]
- Compared to catheter angiography, MRA is less invasive, cheaper, and does not expose patients to ionizing radiation.[1]
- Various MRA techniques allow for quantification of blood flow as well as evaluation of oxygen saturation, which are not possible with CTA.[1]
- MRA is less dependent on the operator compared to vascular ultrasound and is less prone to limitations related to individual body habitus or overlying bowel gas.[1]
- Disadvantages of MRA are motion artifact and risk of nephrogenic systemic fibrosis with gadolinium exposure in individuals with severe renal insufficiency.[1]

Liver Elastography (AB-45)

AB.LE.0045.A

v1.0.2026

- Initial staging of liver fibrosis in suspected fatty liver disease (hepatic steatosis):
  - Transient Elastography or Vibration-Controlled Transient Elastography (VCTE, e.g. Fibroscan) (CPT® 91200) is medically necessary as the initial imaging modality.
    - Typically repeated within a 3-year period. If repeat transient elastography fails, see MRE criteria below
  - Magnetic Resonance Elastography (MRE, CPT® 76391) is medically necessary for ANY of the following:
    - Transient Elastography failure despite use of an XL-probe, OR BMI ≥35
    - Conflict between clinical picture and transient elastography results (e.g., individual with portal hypertension but VCTE suggests no fibrosis)
    - VCTE liver stiffness measurement of ≥8 kPa
    - FIB 4 score of >2.67
    - Liver biopsy demonstrates fibrosis stage F2-F4
- Special considerations for MRE:
  - For MRE requests in the setting of hemochromatosis, see: **Hereditary (Primary) Hemochromatosis (HH) and Other Iron Storage Diseases (AB-11.2)**)
  - For individuals for whom drug treatment is a consideration and EITHER of the following:
    - Evaluation for liver stiffness as part of required assessment for drug candidacy
    - Evaluation for liver stiffness to assess treatment efficacy as required by the drug manufacturer and/or FDA
  - Note: The correct CPT code for MR Elastography is CPT® 76391. It is a stand-alone code and it does not require an additional CPT code such as MRI Abdomen (CPT® 74183).
  - An additional MRI Abdomen code should only be approved if there is another appropriate indication for it, other than the Elastography study (for example, MRE for fibrosis scoring in MASLD (formerly known as NAFLD) due to a BMI ≥35, AND further evaluation of an indeterminate hepatic lesion).
- The use of other ultrasound elastographic codes (CPT® 76981, CPT® 76982, and CPT® 76983) is not medically necessary.

Background and Supporting Information

- For the assessment of fibrosis in chronic liver disease, the American Gastroenterological Association recommends Vibration Controlled Transient Elastography (VCTE) as the preferred imaging modality over MR Elastography

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

(MRE), except in the case of MASLD (formerly known as NAFLD) in high-risk populations.

- Transient Elastography (VCTE) is the most studied elastography technique and informs multiple evidence-based guidelines with respect to fibrosis scoring. No national evidence-based guideline recommends the use of either Acoustic Radiation Force Impulse Imaging (ARFI) or real-time tissue elastography (RTTE) over the use of VCTE for any clinical protocol, nor is there direct evidence that ARFI or RTTE improves health outcomes over and above VCTE.
- Vibration-Controlled Transient Elastography (VCTE) (e.g. Fibroscan, CPT® 91200) may be considered medically necessary to assess for advanced fibrosis and cirrhosis in conditions including:
  - Hepatitis C
  - Hepatitis B
  - Chronic alcoholic liver disease
  - All other chronic liver diseases
- Liver fibrosis staging: The most common staging system is METAVIR, which uses a scale of F0 to F4 (F0 indicates no fibrosis, while F4 represents cirrhosis). Other staging systems include Ishak and Batts-Ludwig, which also assess fibrosis based on histological examination of liver tissue. For Ishak Scoring System: Stages 0-5: Progressively more severe fibrosis, with stage 5 being the most advanced before cirrhosis; Stage 6: Cirrhosis. For Batts-Ludwig Scoring System: Grades 0-4: Progressively more severe fibrosis, with grade 4 being cirrhosis.
- FIB-4 index is calculated as follows[22]:
  - FIB-4 = (Age in years x AST level)/(Platelet count x √ of ALT)

Evidence Discussion

Targeted screening of populations at increased risk for advanced liver disease is advised to identify and manage those with clinically significant fibrosis.[10,22,23,26]

Although liver biopsy remains the reference standard for the grading and staging of nonalcoholic steatohepatitis (NASH), it has important limitations related to risk, cost, and sampling error. Noninvasive biomarkers are emerging as valuable tools for predicting adverse liver-related outcomes.[10,22,23,26]

The most validated laboratory-based fibrosis biomarker is FIB-4, which outperforms other calculations in its ability to identify individuals with a low probability of advanced fibrosis. A FIB-4 score > 2.67 is associated with a high risk of advanced fibrosis.[10,22,23,26]

Liver stiffness is a physical characteristic of the liver that increases with fibrosis severity. Vibration Controlled Transient Elastography (VCTE), e.g., Fibroscan, is the most commonly used method to assess liver stiffness. Transient elastography (VCTE) is the

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

most studied elastography technique and informs multiple evidence-based guidelines with respect to fibrosis scoring. No national evidence-based guideline recommends the use of either ARFI or real-time tissue elastography (RTTE) over the use of VCTE for any clinical protocol, nor is there direct evidence that ARFI or RTTE improves health outcomes over and above VCTE. VCTE-derived liver stiffness measurement (LSM) of < 8 kPa can be used to rule out advanced fibrosis, especially if used with FIB-4. An LSM between 8 and 12kPa may be associated with fibrotic NASH, and a value > 12 kPa is associated with a high likelihood of advanced fibrosis.[10,22,23,26]

For the assessment of cirrhosis in individuals with hepatitis C, the American Gastroenterological Association (AGA) noted that VCTE was recommended over MRE with the exception of NAFLD in high-risk populations, in which MRE resulted in a lower rate of false positives compared to VCTE.[10,22,23,26]

Magnetic Resonance Elastography (MRE) is not the first-line approach for risk stratification, however it becomes an important tool when clinical uncertainty exists, concomitant cross-sectional imaging is needed, there is a discrepancy between the clinical picture and VCTE results, or when VCTE is unavailable or limited by individual factors.[10,22,23,26]

Liver stiffness measurements can provide important context when evaluating individuals for potential drug therapy. While not a formal requirement, imaging-based fibrosis assessment is often part of a comprehensive clinical evaluation.[27]

Liver stiffness can also be used to monitor response to therapy over time. For individuals undergoing treatment with Resmetirom, a follow-up elastography assessment at 12 months may help determine whether the therapy is effective or if adjustments are needed.[27]

Hiccups (AB-46.0)

AB.HI.0046.0.A

v1.0.2026

- Hiccups may be associated with cerebrovascular disease, brain tumors, and intracranial injury, though it would be very rare for hiccups to be the only presenting symptom of serious neurologic disease. If concern is expressed for neurologic involvement, please see the appropriate guideline in HD imaging (e.g., **Neuromyelitis Optica and NMO Spectrum Disorders (HD-16.2)** and **Anti-MOG syndromes (HD-16.3)**)
- Hiccups <48 hours without any localizing or specific symptoms:
  - No advanced imaging is medically necessary
- Hiccups ≥48 hours:
  - History and physical examination, laboratory and CMP and baseline chest x-ray
  - Abnormal or negative chest x-ray with symptoms referable to the chest:
    - CT Chest with contrast (CPT® 71260) is medically necessary
  - Lab or history/physical findings suggest a gastrointestinal etiology:
    - CT Abdomen with contrast (CPT® 74160) is medically necessary

Evidence Discussion

If there are additional signs or symptoms to evaluate, further testing is medically necessary. CT Chest and/or bronchoscopy is the study of choice for evaluation wheezing, dyspnea, abnormal chest radiography, or abnormal pulmonary function tests. MRI Brain and/or lumbar puncture are indication for potential central nervous system causes. Evaluation of esophageal and other symptoms is performed with upper endoscopy, esophageal manometry, and/or CT Abdomen. Cardiac etiologies may be evaluated with EKG & Echo.[3-6]

Retroperitoneal Fibrosis (AB-47.0)

AB.RP.0047.0.A
v1.0.2026

- Individuals diagnosed with retroperitoneal fibrosis:
  - ONE of the following every 3 months is medically necessary until stability demonstrated:
    - CT Abdomen and Pelvis with contrast (CPT® 74177)
    - MRI Abdomen and Pelvis without contrast (CPT® 74181 and CPT® 72195)
    - MRI Abdomen and Pelvis with and without contrast (CPT® 74183 and CPT® 72197)
    - Retroperitoneal or Abdominal ultrasound (CPT® 76770 or CPT® 76700) can be considered medically necessary if requested.
  - After stability established repeat imaging is medically necessary every 6 months.
  - Requests for non-contrasted studies in individuals with renal insufficiency is medically necessary. Gadolinium may induce nephrogenic systemic fibrosis in individuals with moderate or severe renal insufficiency, especially if the GFR is <30 ml/min.
  - Additional imaging:
    - CT Chest (CPT® 71260) is also medically necessary upon initial diagnosis if requested, to further evaluate for the possibility of malignancy as an underlying etiology.
- PET/CT (CPT® 78815)
  - Can be considered medically necessary initially, after diagnosis, to establish avidity patterns to assess for the likelihood of malignancy and for stratification for the likelihood of response to steroids.
  - Follow-up is considered medically necessary if there is documentation of an anticipated therapeutic change based on the results (such as a change in immunosuppression therapy or stent removal).
- Methysergide-induced retroperitoneal fibrosis:
  - Methysergide for migraine treatment is generally no longer available but is rarely being used at some centers. It has a known complication of retroperitoneal fibrosis.
  - Individual screening is medically necessary at baseline and then every 6 months with ONE of the following:
    - CT Abdomen and Pelvis with contrast (CPT® 74177)
    - CT Abdomen and Pelvis without contrast (CPT® 74176)
    - MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197)
    - MRI Abdomen and Pelvis without contrast (CPT® 74181 and CPT® 72195)

- Retroperitoneal ultrasound (CPT® 76770 or CPT® 76775)

Background and Supporting Information

Retroperitoneal fibrosis is a rare disease, and may be idiopathic (IgG4 or non-IgG-4 related) or secondary. Secondary causes include malignancy, infections, previous radiation therapy, previous abdominal surgery, drugs such as methysergide, and biologic agents.

Evidence Discussion

- Ultrasound may be used as a screening tool, but has low sensitivity and is often insufficient to distinguish retroperitoneal fibrosis from other abdominal masses.[2]
- CT and MR allow for characterizing morphology and extent of retroperitoneal fibrosis both at initial diagnosis and in treatment monitoring. It also helps to define the involved vascular structures, and can visualize disease in other abdominal viscera that may be associated with retroperitoneal fibrosis. CT may have advantages in imaging availability and imaging time. MR may have advantages in avoiding ionizing radiation and improved soft tissue characterization.[1]
- PET may be used to evaluate metabolic activity and may be of value after diagnosis to characterize active inflammation versus malignancy and to document response to treatment. The role of PET scan in establishing a diagnosis is limited due to the potential for nonspecific uptake.[1,6,7]
- Follow-up may be appropriate every 3-12 months to access disease status and response to therapy.[1]

Fistulae (AB-48)

AB.FD.0048.A
v1.0.2026

- Suspected enteric fistulae
  - ONE of the following is medically necessary:
    - MR Enterography (CPT® 74183 or CPT® 74181 and CPT® 72197 or CPT® 72195), OR
    - CT Enterography or CT Abdomen and Pelvis with contrast (CPT® 74177), OR
    - MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197)
- Suspected colovesical fistulae
  - ONE of the following is medically necessary:
    - CT Abdomen and Pelvis without contrast (CPT® 74176), OR
    - MR Enterography (CPT® 74183 or CPT® 74181 and CPT® 72197 or CPT® 72195), OR
    - MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT® 72197)
- Enterocutaneous fistulae
  - Suspected enterocutaneous fistulae or surgical planning of known complex fistulae:
    - ONE of the following is medically necessary:
      - CT Abdomen and Pelvis with contrast (CPT® 74177), OR
      - MR Enterography (CPT® 74183 or CPT® 74181 and CPT® 72197 or CPT® 72195), OR
      - MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and CPT®72197)
- Complicated diverticulitis with fistula, see: **Lower Abdominal Pain (AB-2.2)**
- Perianal/perirectal fistulae and abscess related to Crohn's disease, see: **Perirectal/ Perianal Crohn's Disease (AB-23.3)**
- Other fistulae related to Crohn's disease, see: **Known IBD (AB-23.2)**
- Perianal/perirectal fistulae NOT related to Crohn's disease, see: **Fistula in Ano (PV-21.1)** in the Pelvis Imaging Guidelines
- For colovaginal, rectovesicular, rectovaginal, or urinary-vaginal communicating fistulae, see: **Pelvic Fistula (PV-21.3)** in the Pelvis Imaging Guidelines
- For pilonidal cyst, see: **Pilonidal Cyst (PV-21.4)** in the Pelvis Imaging Guidelines

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Background and Supporting Information

- Examples of gastrointestinal fistulae include tracheo- and broncho-esophageal, entero-cutaneous, entero-enteric, entero-colic, entero-vesical, colo-vesical, recto-vaginal, perianal, and aorto-enteric.
- Etiologies of fistulae include: complication of inflammatory disease (e.g., Diverticulitis, Crohn's disease), complication of surgical procedures (which are the most common cause of intestinal fistula, comprising more than half of all fistulae), obstetric injury (e.g., recto-vaginal, ano-vaginal), malignancy, radiation, non-surgical injuries, and foreign bodies.

Evidence Discussion

Magnetic resonance imaging (MRI) and small intestine contrast enhanced ultrasonography (SICUS) have now emerged as suitable radiation-free alternatives to CT imaging, with comparable diagnostic accuracy. MRI is often considered the imaging modality of choice for evaluation of fistulae owing to its superior soft-tissue contrast and ability to provide surgeons with the highest quality information derived from just one study, including anatomic location of fistulae and associated pelvic pathology.[1,2,11,12,13]

General Guidelines (BR-Preface 1.0)

BR.GG.0001.0.A

v2.0.2026

- A current clinical evaluation since the onset or change in symptoms is usually required prior to considering advanced imaging.
  - A clinical evaluation should include the following:
    - A relevant history and physical examination since the onset or change in symptoms
    - Appropriate laboratory studies and non-advanced imaging modalities, such as mammogram and/or ultrasound
    - Other meaningful contact (telephone call, electronic mail or messaging) since the onset or change in symptoms by an established individual can substitute for a face-to-face clinical evaluation
- Current clinical evaluation is not required prior to screening studies.

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

BI-RADS™ Categories Chart (BR-Preface 1.1)

BR.GG.0001.1.A

v2.0.2026

BI-RADS™ Categories Chart	
Category	**Description**
Category 0: Incomplete	Need additional imaging evaluation or prior mammograms for comparison. Category 0 classification requires that additional imaging study be specified, e.g., ultrasound, additional mammogram view, MRI.
Category 1: Negative	There is nothing to comment on. The breasts are symmetrical and no masses, architectural disturbances, or suspicious calcifications are present.
Category 2: Benign Finding	This is also a negative mammogram, but the interpreter may wish to describe a finding. Involuting, calcified fibroadenomas, multiple secretory calcifications, fat-containing lesions (such as oil cysts, lipomas, galactoceles, and mixed density hamartomas) all have characteristic appearances, and may be labeled with confidence. The interpreter might wish to describe intramammary lymph nodes, implants, etc. while still concluding that there is no mammographic evidence of malignancy.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

BI-RADS™ Categories Chart	
Category	**Description**
Category 3: Probably Benign Finding – Short Interval Follow-up Suggested	A finding placed in this category should have a very high probability of being benign. It is not expected to change over the follow-up interval, but the radiologist would prefer to establish its stability. Data is becoming available that sheds light on the efficacy of short interval follow-up. At the present time, most approaches are intuitive. These will likely undergo future modification as more data accrue as to the validity of an approach, the interval required, and the type of findings that should be followed.
Category 4: Suspicious Abnormality – Biopsy Should Be Considered	There are lesions that do not have the characteristic morphologies of breast cancer but have a definite probability of being malignant. The radiologist has sufficient concern to urge a biopsy. If possible, the relevant possibilities should be cited so that the individual and their physician can make the decision on the ultimate course of action.
Category 5: Highly Suggestive of Malignancy – Appropriate Action Should Be Taken	These lesions have a high probability of being cancer and should be biopsied or treated surgically.
Category 6: Known Biopsy-Proven Malignancy – Appropriate Action Should Be Taken	These lesions have been biopsied and are known to be malignant.

Breast Ultrasound (BR-1.1)

BR.US.0001.1.A
v2.0.2026

- Routine performance of breast ultrasound (US) as stand-alone screening or with screening mammography is not medically necessary.
  - Breast ultrasound is a supplemental screening alternative for high-risk females (as described in **MRI Breast Indications [BR-5]**) with dense breasts on mammography, when MRI Breast without and with contrast cannot be performed. The inability to perform MRI Breast may be because it cannot be tolerated (i.e., insurmountable claustrophobia or body habitus), or there exists a contraindication (i.e., non-MRI compatible implantable devices or an inability to receive MRI contrast).
  - Breast ultrasound (CPT® 76641 or CPT® 76642) is medically necessary when requested by the treating provider to complete the screening process, OR recommended by the radiologist report, OR to address a finding on the mammogram.
- Breast ultrasound (CPT® 76641: unilateral, complete; or, CPT® 76642: unilateral, limited) can be used to further evaluate abnormalities found on mammogram, especially in differentiating cysts from solid lesions.
  - A clinical office visit is not necessary prior to breast ultrasound when an abnormality has been identified on a mammogram.
- BI-RADS™ Cat 3 ultrasound follow-up imaging for stable findings at 6 months:
  - if repeat imaging remains BI-RADS™ 3, repeat at 12 months, 18 months, and 24 months from the date of the initial imaging.
    - After 2 years of stability, the finding should be assessed as benign (Cat 2).
  - if repeat imaging is BI-RADS™ 1 or 2, then imaging reverts to routine per individual's risk profile.
- For breast implant imaging, please see **Breast Implant Evaluation (BR-5.2)**.
- Axilla ultrasound (CPT® 76882)
  - For individuals with clinically suspicious lymph nodes, pre-operative axillary ultrasound with a FNA or biopsy can help identify individuals who have positive nodes.
    - See **Axillary Lymphadenopathy (and Mass) (CH-2.2)** in the Chest Imaging Guidelines.
  - Bilateral should be coded CPT® 76882 x 2.
- US-guided breast biopsy (CPT® 19083) includes the imaging component.
  - Additional lesions should be billed using CPT® 19084.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Breast ultrasound (CPT® 76641 or CPT® 76642) can be repeated at least 6 months after an US-directed breast biopsy to document successful lesion sampling if histology is benign and non-specific, equivocal or uncertain.
- 3D Reconstruction (CPT® 76376 or CPT® 76377) is **NOT** medically necessary for breast ultrasound. It is commonly requested in conjunction with automated breast ultrasound (ABUS); there is no evidence to support its clinical usefulness.

MRI Breast Coding (BR-2.1)

BR.MR.0002.1.A

v2.0.2026

- The use of gadolinium contrast is required for the evaluation of breast parenchyma.
- The use of gadolinium contrast is **NOT** medically necessary for the evaluation of implant integrity in asymptomatic, average-risk individuals.
- Throughout this guideline, when MRI Breast is medically necessary, either **ONE** of the following codes is supported (unless otherwise specified per indication):
  - CPT® 77049 MRI Breast Bilateral, including CAD, without and with contrast
  - HCPCS C8908 MRI Breast Bilateral, without and with contrast
- If the individual meets medical necessity for advanced imaging to assess implant integrity, the appropriate code is CPT® 77047 MRI Breast Bilateral, without contrast.
- Computer-aided detection (CAD) is included with the MRI Breast CPT® 77049 and CPT® 77048 procedures.
  - The use of CAD has little influence on the sensitivity and specificity of MRI Breast interpretation.
  - Since the CAD software automatically performs 3D imaging, CPT® 76376 or CPT® 76377 should **NOT** be used in conjunction with MRI Breast.
- MRI-guided breast biopsy (CPT® 19085) includes the imaging component and the needle placement under MR guidance; CPT® 77021 MR guidance for needle placement is **NOT** an appropriate code to bill for a breast biopsy.
  - Additional lesions should be billed using CPT® 19086.
  - This program does not manage CPT® codes 19085 or 19086.
- Intraoperative placement of a breast localization device includes the imaging component. For this reason, CPT® 77021, MR guidance for needle placement, is **NOT** an appropriate code to bill for pre-operative localization.
  - Diagnostic MRI Breast is not medically necessary for localization.

Background and Supporting Information

- Although MRI Breast has superior sensitivity in identifying new unknown malignancies, it carries a significant false positive risk when compared to mammogram and ultrasound. Incidental lesions are seen on 15% of MRI Breast and increase with younger age. The percentage of incidental lesions that turn out to be malignant varies from 3% to 20% depending on the individual population. Cancer is identified by MRI Breast in only 0.7% of those with “inconclusive mammographic lesions.”

Copyright ©2026 United HealthCare Services, Inc.

Breast Reconstruction (BR-3.1)

BR.RC.0003.1.A
v2.0.2026

- CTA or MRA of the body part **from which the free-tissue transfer flap is being taken**, can be performed for breast reconstruction pre-operative planning.
  - Examples include:
    - CTA Abdomen and/or Pelvis (CPT® 74175 or CPT® 72191 or CPT® 74174) or MRA Abdomen and/or Pelvis (CPT® 74185 and/or CPT® 72198) for Deep Inferior Epigastric Perforators (DIEP) flap
    - CTA Chest (CPT® 71275) for Thoracodorsal Artery Perforator (TDAP) flap
- Routine use of CTA Chest (CPT® 71275) to evaluate **recipient** vessels is **NOT** medically necessary.
  - **Criteria exception**: In circumstances where there has been previous cardiac/vascular surgery and/or known vascular anomalies in the chest, it may be warranted.
- There is currently insufficient evidence-based data to support the need for routine advanced imaging for TRAM flaps or other flaps performed on a vascular pedicle.

Evidence Discussion

The American College of Radiology (ACR) Appropriateness Criteria® stated that either MRA abdomen and pelvis with and without IV contrast or CTA abdomen and pelvis with IV contrast are usually appropriate for pre-operative planning in individuals undergoing DIEP flap breast reconstruction.[2] Studies have found CTA mapping results in a shorter operative time when compared with no mapping in cases of breast reconstruction with free-tissue flap transfer (e.g., with Deep Inferior Epigastric Perforator (DIEP) flaps).[1]

In contrast, routine use of CTA chest to evaluate for recipient vessels (often the internal mammary vessels) is not medically necessary. This is because a number of studies have found that the anatomy and course of these vessels is largely consistent, and that there is good concordance between surgical and radiological findings – either with ultrasound or CTA.[3] CTA, however, carries with it significant risks, including contrast nephrotoxicity and allergic reactions, and the significantly higher risk of radiation exposure in the chest than in the abdomen.[4] As such, many surgeons will use hand-held Doppler ultrasound either pre- and/or intra-operatively to evaluate recipient vessels. In certain circumstances, such as with previous surgery and/or radiation that would be expected to affect the candidacy of potential recipient vessels, pre-operative CTA of the chest may be considered.

As pedicled flaps, by definition, do not require a microvascular anastomosis and are not disconnected from their blood supply, there is no current evidence to support routine pre-operative imaging in these individuals. A recent study evaluating the use of pre-

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

operative CTA in individuals undergoing pedicled TRAM flap reconstruction found that there was no significant difference in terms of operative time nor flap loss in individuals who had a pre-operative CTA compared to those who did not.[5]

Per the National Comprehensive Cancer Network (NCCN), "common donor sites for autologous tissue include the abdomen (ie, DIEP, MS TRAM [Muscle-Sparing Transverse Rectus Abdominis Myocutaneous], SIEA [Superficial Inferior Epigastric Artery], free TRAM, pedicled TRAM), gluteal region (ie, SGAP [Superior Gluteal Artery Perforator], IGAP [Inferior Gluteal Artery Perforator]), thigh (ie, TUG [Transverse Upper Gracilis], VUG [Vertical Upper Gracilis], DUG [Diagonal Upper Gracilis], PAP [Profunda Artery Perforator]), or the back (ie, LD [Latissimus Dorsi], TDAP, LAP [Lumbar Artery Perforator])".[46]

MRI Breast Indications (BR-5.1)

BR.ID.0005.1.A
v2.0.2026

MRI Breast Considerations

- When MRI Breast imaging is medically necessary (per the criteria listed in the sections below), an MRI Breast Bilateral without and with contrast (CPT® 77049 or HCPCS C8908) is medically necessary (unless other codes are specified).
- MRI Breast Unilateral is **NOT** clinically supported (except as specified below).
- See **Breast Ultrasound (BR-1)** when there is a contraindication to MRI contrast.
- See **MRI Breast Coding (BR-2)** for MRI-guided breast biopsy.
- See **Breast Cancer (ONC-11)** in the Oncology Imaging Guidelines for imaging indications related to breast cancer as follows:
  - Breast Cancer - Initial work-up/Staging
  - Breast Cancer - Restaging/Recurrence
  - Breast Cancer - Surveillance/Follow-up
  - Annual screening with prior history of breast cancer

MRI Following a Screening Mammogram and/or US in Asymptomatic Individuals

- MRI Breast Bilateral without and with contrast (CPT® 77049 or HCPCS C8908) is medically necessary for **EITHER** of the following:
  - When requested by the treating provider to complete the screening process, OR recommended by the radiologist report, OR to address a finding on the mammogram.
    - When medical necessity is met with one of the indications in the bullet above, any ONE of the following codes are acceptable:
      - CPT® 77046 (MRI Breast Unilateral without contrast)
      - CPT® 77047 (MRI Breast Bilateral without contrast)
      - CPT® 77048 (MRI Breast Unilateral without and with contrast)
      - CPT® 77049 (MRI Breast Bilateral without and with contrast)
      - HCPCS C8903 (MRI Breast Unilateral with contrast)
      - HCPCS C8905 (MRI Breast Unilateral without and with contrast)
      - HCPCS C8906 (MRI Breast Bilateral with contrast)
      - HCPCS C8908 (MRI Breast Bilateral without and with contrast)
  - Documented histopathologic discordance between core-needle biopsy findings and imaging findings. MRI Breast is medically necessary for further evaluation **after** the discordant biopsy (before consideration for surgical management vs. observation).

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

    - Discordance exists when the biopsy result does not adequately explain the abnormal (BI-RADS™ 4 or 5) findings on mammogram and/or ultrasound.
- For symptomatic individuals, please refer to the following appropriate condition-based guideline:
  - **Nipple Discharge/Galactorrhea (BR-6.1)**
  - **Breast Pain (Mastodynia) (BR-7.1)**
  - **Breast Imaging in Males (BR-9.1)**
  - **Breast Mass (BR-14.1)**
  - **Skin Changes (BR-15.1)**
  - **Nipple Inversion/Retraction (BR-16.1)**
  - **Malignant Phyllodes Tumor/Cystosarcoma Phyllodes (BR-17.1)**
- See **MRI BI-RADS™ 3** section for lesions categorized as BI-RADS™ 3 on MRI.

MRI BI-RADS™ 3

- A probably benign lesion on **MRI** (MRI BI-RADS™ 3) should undergo repeat MRI in 6 months.
  - If repeat imaging remains MRI BI-RADS™ 3, then repeat at 12 months, 18 months, and 24 months from the date of the initial imaging.
    - After 2 years of stability, the finding should be assessed as benign (Cat 2)
  - If repeat imaging is BI-RADS™ 1 or 2, then imaging reverts to routine per individual's risk profile. See **Risk Factors** section.

Post-Biopsy or Attempted Biopsy Imaging

- For lesions initially seen on MRI Breast and that have benign and non-specific, equivocal or uncertain histology (based on a stereotactic, MRI-guided, or US-directed breast biopsy), an MRI Breast Bilateral without and with contrast (CPT® 77049 or HCPCS C8908) is medically necessary at least 6 months after the biopsy to document successful lesion sampling.
- MRI Breast Bilateral without and with contrast (CPT® 77049 or HCPCS C8908) is medically necessary 6 months after attempted MRI-guided breast biopsy, when recommended by a radiologist, due to targeted lesion not visualized at the time of the procedure.

Risk Factors

- Routine MRI Breast following bilateral mastectomy is **NOT** medically necessary (even if high-risk screening criteria may otherwise be met and/or nipple-sparing mastectomy was done).
- Annual MRI Breast screening with MRI Breast Bilateral without and with contrast (CPT® 77049 or HCPCS C8908) is medically necessary for individuals meeting the

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

high-risk criteria in the table below (for male breast imaging, please see **Breast Imaging in Males (BR-9.1)**):

High-Risk Indications	Age at which screening can start**
Genetic Mutations:*	
Li-Fraumeni (p53)	20
BRCA 1 or 2	25
STK11, Peutz-Jeghers syndrome (PJS), PTEN Mutation (Cowden Syndrome), CDH1, NF1, PALB2, ATM, CHEK2	30**
BARD1, RAD51C, RAD51D	40**
Personal history of atypia/LCIS/breast cancer:	
ADH, ALH, LCIS	At diagnosis but not prior to age 25
Personal history of breast cancer at or before the age of 50	At diagnosis
Family history:	
If the individual has **NOT** been tested for BRCA mutation **and** there is a first-degree relative (parent, sibling, child; half-siblings are considered second-degree relatives) with BRCA 1 or BRCA 2 mutation. Annual screening is **NOT** medically necessary if the individual has been tested and is negative for BRCA 1 or BRCA 2 mutation unless they meet other criteria.	40**
Two or more first-degree relatives with breast or ovarian cancer	40**
One first-degree relative with breast cancer or ovarian cancer that was diagnosed ≤ age 50	40**
One first-degree relative with bilateral breast cancer, or both breast and ovarian cancer	40**
A first- or second-degree male relative (father, brother/half-brother, uncle, grandfather) diagnosed with breast cancer	40**
Elevated clinical lifetime-risk:	

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

High-Risk Indications	Age at which screening can start**
Clinical lifetime-risk estimated at greater than or equal to 20% as calculated by one of the following models: • Gail (National Cancer Institute (NCI)) • Tyrer-Cuzick (International Breast Cancer Intervention Study (IBIS)) • The Breast Cancer Surveillance Consortium (BCSC) • Breast and Ovarian Analysis of Disease Incidence and Carrier Estimation Algorithm (BOADICEA)/CanRisk • BRCAPRO Model	40**
Personal history of radiation therapy when younger than age 30:	
Radiation to chest, whole lung, mediastinum, axilla, mantle (including mini mantle or extended mantle), total or subtotal lymphoid irradiation or total body irradiation (TBI)	25 or 8 years after completion of radiation therapy *whichever comes later*
Breast Density:	
Heterogeneously Dense Breasts (Category C) or Extremely Dense Breasts (Category D) with no additional risk factors	40

*The following have unknown or insufficient evidence of breast cancer risk and additional MRI screening is NOT medically necessary at this time: MSH2, MLH1, MSH6, PMS2, EPCAM, NBN, genetic variants of unknown significance, genetic variants favoring polymorphism, and genetic variants of intermediate penetrance. Any gene mutation not specified in the table above has not currently been found to have sufficient evidence to support surveillance with MRI.

OR 10 years prior to the age of diagnosis of the earliest relative with breast cancer (first-, second-, and third-degree relatives) *whichever comes first*, **but not before age 25

Background and Supporting Information

- myRisk® Hereditary Cancer (Myriad Genetics, Inc.) is not accepted as a risk calculator to determine high-risk for breast cancer.

Evidence Discussion

High-Risk Indications

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Li-Fraumeni Syndrome is associated with an increased incidence of premenopausal breast cancer, with the median age of diagnosis being in the early 30s.[10] Accordingly, the National Institute for Health and Care Excellence (NICE)[9] recommended annual MRI screening beginning at age 20.[9]

While the American Cancer Society (ACS) found that there is not enough evidence to make a recommendation for or against screening MRI in these populations[6], the NCCN has recommended annual breast MRI for those with ADH, ALH or LCIS who have at least a 20% residual lifetime risk of developing breast cancer. Screening could begin at the age of diagnosis of ADH or lobular neoplasia, but not before the age of 25. They further noted that the residual lifetime risk calculation depends on the age at diagnosis.[7]

BRCA1 and *2* are associated with a risk of developing breast cancer >60%.[8] The NCCN guidelines recommended starting MRI screening at the age of 25.[8]

STK11 mutations are associated with a 32%-54% risk of developing primary breast cancer. *CDH1* and *PALB2* mutations each confer a risk of 41%-60% of developing breast cancer. NCCN guidelines recommended starting MRI screening in these individuals at age 30. For individuals with NF1, the risk of developing breast cancer is 20%-40%. NCCN guidelines recommended considering annual MRI screening from ages 30-50. *ATM* mutations are associated with a 20%-30% risk of developing breast cancer, and *CHEK2* mutations similarly are associated with a 20%-40% risk. NCCN guidelines suggested consideration of annual breast MRI starting at age 30-35 in both of these groups. *PTEN* mutations are associated with a 40%-60% risk of developing breast cancer. While NCCN guidelines are silent on breast cancer screening for this population, ESMO guidelines recommended starting annual MRI at the age of 30.[8,11]

BARD1, *RAD51C* and *RAD51D* are each associated with a 17%-30% risk of developing breast cancer. The NCCN guidelines recommended considering an annual breast MRI starting at age 40.[8]

However, mutations and variants with a <15% absolute risk of developing breast cancer lack sufficient evidence to suggest that screening MRI would be beneficial. Therefore, the NCCN did not recommend screening MRI for these individuals unless other risks are present.[8]

The ACR Appropriateness Criteria® for "Female Breast Cancer Screening" had noted that "some females with a personal history of breast cancer may also fit into the high-risk category, particularly those diagnosed before 50 year of age...".[42] They also went on to state that these women may have a greater than 20% estimated lifetime risk of another breast cancer diagnosis.[42] The NCCN also noted that MRI Breast for screening is recommended annually for individuals diagnosed with breast cancer at or before age 50[46] who have not undergone bilateral mastectomy (see the "**Postmastectomy Imaging**" section below).

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

The ACS considered individuals who have a first-degree relative with a BRCA 1 or 2 gene mutation and who have not been tested themselves to be at high risk. They recommended an annual MRI screening starting at age 30.[6] On the other hand, NCCN guidelines suggested that untested individuals with a first-degree relative with a BRCA 1 or 2 mutation should start screening either 10 years before the youngest family member was diagnosed with breast cancer, but not before age 25, or at age 40, whichever comes first.[7]

Per NCCN recommendations, BRCAPRO, Tyrer- Cuzick, Breast Cancer Surveillance Consortium (BCSC), and Breast and Ovarian Analysis of Disease Incidence and Carrier Estimation Algorithm (BOADICEA)/CanRisk are appropriate models used to calculate clinical lifetime-risk.[46]

The NCCN has issued guidance that recommended individuals with extremely dense breast tissue on mammogram begin screening with MRI Breast at age 50, but also notes that "consideration can be given to start at age 40 based on individual risk factors".[7] The Updated Recommendations from ACR also addressed the use of MRI Breast in individuals with dense breast tissue for supplemental screening. They did not differentiate between heterogeneously and extremely dense breasts in their recommendation and instead, recommended screening for those with dense breasts starting at age forty.[84] ACR considers dense breasts to be heterogeneously dense (Category C) and extremely dense (Category D).[85]

MRI utilizes a magnetic field and radio waves with computer processing to produce detailed images whereas CT uses ionizing radiation. Radiation dosages vary based on many factors and can be harmful to tissues. Thus, from a radiation safety perspective, MRI should be utilized when appropriate and supported by existing literature; however, the NCCN also acknowledged potential harms of MRI use, such as increased false positives, increased recall, and increased benign biopsies.[7]

Post-Biopsy or Attempted Biopsy Imaging

A study conducted by Pinnamaneni et al showed that of the 89 biopsies that were canceled secondary to nonvisulaization, 74% of lesions resolved by 6 month follow-up, however 1.9% yielded carcinoma at the 6 month follow-up. Pinnamaneni et al. concluded that, "the majority of canceled MRI-guided biopsy lesions resolved on later follow-up; however, because of the small possibility of a missed malignancy, follow-up MRI imaging at 6 months is recommended".[90]

The initial evaluation of individuals who present with a suspicious finding on breast imaging or a palpable mass upon examination involves a biopsy (percutaneous or surgical if percutaneous is not feasible). If the biopsy results are discordant with the imaging findings, an MRI for further evaluation is supported.[16]

Postmastectomy Imaging

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

According to the ACR Appropriateness Criteria® for "Imaging after Mastectomy and Breast Reconstruction", there is not enough evidence to support MRI imaging for breast cancer screening following a bilateral mastectomy.[73] In addition, in a study by Weed et al, it was found that "the use of surveillance MRI after NSM [nipple-sparing mastectomy] lead to increased rates of biopsy without improvement in overall survival in our study".[88]

Breast Implant Evaluation (BR-5.2)

BR.ID.0005.2.U
v2.0.2026

Breast Implant Imaging

- Breast MRI is **NOT** medically necessary for evaluation of capsular contracture.
- Imaging for routine surveillance and/or suspected rupture of breast implants is dependent upon the type of implant. Please see below.

SALINE

Asymptomatic Screening in Females or Transfeminine Individuals

- For all ages, routine imaging is not medically necessary.

Exam Equivocal for Rupture in Females or Transfeminine Individuals

- If less than 30 years old, breast ultrasound (CPT® 76641 or CPT® 76642) is medically necessary.
- If 30 years old or older, breast ultrasound (CPT® 76641 or CPT® 76642) or diagnostic mammogram is medically necessary.
- If breast ultrasound or diagnostic mammogram results are indeterminate for saline implant rupture, additional imaging with MRI Breast Bilateral without contrast (CPT® 77047) is medically necessary for further evaluation.

SILICONE

Asymptomatic Screening in Females or Transfeminine Individuals

- For all ages, if it is less than 5 years since the implants were placed, routine advanced imaging is not medically necessary.
- For all ages, if it has been 5 years or more since the implants were placed, breast ultrasound (CPT® 76641 or CPT® 76642) is considered medically necessary.
  - Further evaluation with MRI Breast Bilateral without contrast (CPT® 77047) is medically necessary if the breast ultrasound is indeterminate.
  - Repeat breast ultrasounds (CPT® 76641 or CPT® 76642) can be done every 2 to 3 years after initial negative imaging.

Exam Equivocal for Rupture in Females or Transfeminine Individuals

- For all ages, breast ultrasound (CPT® 76641 or CPT® 76642) or diagnostic mammogram or MRI Breast Bilateral without contrast (CPT® 77047) is medically necessary.
- If breast ultrasound (CPT® 76641 or CPT® 76642) or diagnostic mammogram results are indeterminate for silicone implant rupture, additional imaging with MRI Breast Bilateral without contrast (CPT® 77047) is medically necessary for further evaluation.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Evidence Discussion

Breast Implant Evaluation

The two types of breast implants include saline and silicone. Saline implant rupture is more clinically apparent, since the body readily resorbs the leaking saline and the implant shell appears deflated on exam.[13] Thus, there is no role for MRI Breast(s) in asymptomatic women with saline implants.[14] However, if the exam is equivocal for rupture, initial imaging supported by the ACR includes diagnostic mammogram and/or ultrasound in individuals >30 years old. In those <30 years of age, diagnostic mammogram is not typically performed and ultrasound is the initial imaging of choice.[14]

An exam is not as reliable for detecting the rupture of silicone implants as it is for saline implants. Therefore, if an exam is equivocal for rupture, imaging with a combination of ultrasound, mammogram, and/or MRI of the breast (with the choice of mammogram depending upon age) is appropriate.[15]

Click Here to Return to the Main TOC

Nipple Discharge/Galactorrhea (BR-6.1)

BR.DC.0006.1.A
v2.0.2026

Physiologic nipple discharge (non-spontaneous or multi-duct, no suspicious findings on clinical exam)

- For individuals less than 40 years old, imaging is not medically necessary.
- For individuals 40 years old and older, a screening mammogram is medically necessary.
- If there is concern for a prolactinoma, please refer to **Pituitary, Sella, Hypothalamus (HD-19.1)**.

Pathologic nipple discharge (spontaneous, unilateral, single duct, clear or bloody, persistent and reproducible)

- For individuals less than 30 years old, breast ultrasound (CPT® 76641 or CPT® 76642) with or without a diagnostic mammogram is the medically necessary initial imaging.
  - If the breast ultrasound or diagnostic mammogram (if performed) is a BI-RADS™ category 1-3, a MRI Breast Bilateral without and with contrast (CPT® 77049 or HCPCS C8908) is medically necessary.
  - If the breast ultrasound or diagnostic mammogram (if performed) are a BI-RADS™ category 4 or 5, a MRI Breast is **NOT** medically necessary. Biopsy is recommended in these circumstances.
- For individuals 30 years old and older, breast ultrasound (CPT® 76641 or CPT® 76642) and diagnostic mammogram are the medically necessary initial imaging.
  - If the breast ultrasound or diagnostic mammogram is a BI-RADS™ category 1-3, a MRI Breast Bilateral without and with contrast (CPT® 77049 or HCPCS C8908) is medically necessary.
  - If the breast ultrasound or diagnostic mammogram are a BI-RADS™ category 4 or 5, a Breast MRI is **NOT** medically necessary. Biopsy is recommended in these circumstances.

Background and Supporting Information

- Physiologic nipple discharge is predominantly bilateral but may be unilateral. It is commonly multi-duct. It is predominantly milky but may be white or a variety of colors including serous, yellow, green, brown, or gray. Evaluation for hyperprolactinemia can be considered.
- For milky discharge, prolactin and TSH levels are recommended to diagnose prolactinoma; pituitary imaging is not needed if normal serum Prolactin.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Pathologic nipple discharge is defined as unilateral, bloody or serous, arising from a single duct, persistent, and spontaneous.

Evidence Discussion

No specific breast imaging is used for evaluation of physiologic discharge, other than usual screening mammogram in the appropriate age group. Otherwise, the evaluation is medical, including lab studies to rule out endocrine etiology. In a study of 13,443 women with nipple discharge, 316 (2.3%) had nonspontaneous discharge, only 1 (0.3%) of whom had carcinoma.[19] Similarly, a retrospective review of 273 women who underwent diagnostic and therapeutic surgery for nipple discharge found no malignancies in those presenting with physiologic nipple discharge.[20]

The evaluation of pathologic nipple discharge is aimed at determining if there is an underlying intraductal papilloma, high-risk lesion, or a malignancy. Larger studies estimate the rate of malignancy or high-risk histopathologic lesions to be 11% to 16% of individuals with pathologic nipple discharge.[22] Initial radiographic evaluation includes both diagnostic mammography and targeted breast ultrasound. If both are non-diagnostic, then MRI is the next imaging modality used for evaluation. Contrast-enhanced MRI has demonstrated sensitivities of 93 to 100 percent for invasive cancers as well as benign papillary lesions.[23]

Breast Pain (Mastodynia) (BR-7)

Guideline

Breast Pain (Mastodynia) (BR-7.1)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Breast Pain (Mastodynia) (BR-7.1)

BR.PA.0007.1.A
v2.0.2026

- Evaluation of breast pain requires a history and physical exam.
  - When breast pain is present with another breast symptom such as nipple discharge, skin change(s), or palpable mass, the imaging should be done in accordance with the accompanying symptom's guideline rather than this guideline for breast pain.
- If pain is cyclical and/or generalized across more than one quadrant of the breast, an up-to-date screening mammogram is medically necessary.
- If pain is focal and the individual is 30 years old or older, diagnostic mammogram and breast ultrasound (CPT® 76641 or CPT® 76642) are medically necessary as the initial imaging.
- If pain is focal and the individual is less than 30 years old, breast ultrasound (CPT® 76641 or CPT® 76642) is medically necessary as the initial imaging.
- Advanced imaging is **NOT** medically necessary in individuals with breast pain or breast abscesses.

Background and Supporting Information

- The risk of malignancy following a negative clinical examination (clinical breast exam, mammogram, ultrasound) has been estimated to be only 0.5%.

Evidence Discussion

In a study of 2820 individuals presenting with breast pain, the cancer detection rate in those who underwent breast imaging was found to be 0.09%, 1% and 1.4% in individuals under the age of 40, 40-49 and 50 years of age or older, respectively.[24] Similarly, in a case control study comparing 987 women with painful breasts and 987 controls, the prevalence of breast cancer was similar between the two groups (0.8% vs. 0.7%, respectively).[25] Given these data, in the absence of other factors, the ACR recommends against the use of MRI in individuals with breast pain.[26]

Breast abscesses can present with a variety of etiologies. In a review of various inflammatory diseases of the breast, Scott et al points to ultrasound as the appropriate initial imaging. It is also noted that while diagnostic mammogram can be done, it may not be very beneficial in all etiologies.[92]

Alternative Breast Imaging Approaches (BR-8.1)

BR.AA.0008.1.A
v2.0.2026

Molecular Breast Imaging (MBI)

- Molecular Breast Imaging (CPT® 78800) is supported in individuals who meet criteria for breast cancer screening with MRI (per **BR-5**) but for whom MRI is contraindicated.
  - See "**MRI Following a Screening Mammogram and/or US in Asymptomatic Individuals**" and "**Risk Factors**" below.

MRI Following a Screening Mammogram and/or US in Asymptomatic Individuals

- MRI Breast Bilateral without and with contrast (CPT® 77049 or HCPCS C8908) is medically necessary for **ANY** of the following:
  - when requested by the treating provider to complete the screening process, OR
  - recommended by the radiologist report, OR
  - to address a finding on the mammogram

Risk Factors

- Routine MRI Breast following bilateral mastectomy is **NOT** medically necessary (even if high-risk screening criteria may otherwise be met and/or nipple-sparing mastectomy was done).
- Annual MRI Breast screening with MRI Breast Bilateral without and with contrast (CPT® 77049 or HCPCS C8908) is medically necessary for individuals meeting the high-risk criteria in the table below (for male breast imaging, please see **Breast Imaging in Males (BR-9.1)**):

High-Risk Indications	Age at which screening can start**
Genetic Mutations:*	
Li-Fraumeni (p53)	20
BRCA 1 or 2	25
STK11, Peutz-Jeghers syndrome (PJS), PTEN Mutation (Cowden Syndrome), CDH1, NF1, PALB2, ATM, CHEK2	30**
BARD1, RAD51C, RAD51D	40**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

High-Risk Indications	Age at which screening can start**
Personal history of atypia/LCIS/breast cancer:	
ADH, ALH, LCIS	At diagnosis but not prior to age 25
Personal history of breast cancer at or before the age of 50	At diagnosis
Family history:	
If the individual has **NOT** been tested for BRCA mutation **and** there is a first-degree relative (parent, sibling, child; half-siblings are considered second-degree relatives) with BRCA 1 or BRCA 2 mutation. Annual screening is **NOT** medically necessary if the individual has been tested and is negative for BRCA 1 or BRCA 2 mutation unless they meet other criteria.	40**
Two or more first-degree relatives with breast or ovarian cancer	40**
One first-degree relative with breast cancer or ovarian cancer that was diagnosed ≤ age 50	40**
One first-degree relative with bilateral breast cancer, or both breast and ovarian cancer	40**
A first- or second-degree male relative (father, brother/half-brother, uncle, grandfather) diagnosed with breast cancer	40**
Elevated clinical lifetime-risk:	
Clinical lifetime-risk estimated at greater than or equal to 20% as calculated by one of the following models: • Gail (National Cancer Institute (NCI)) • Tyrer-Cuzick (International Breast Cancer Intervention Study (IBIS)) • The Breast Cancer Surveillance Consortium (BCSC) • Breast and Ovarian Analysis of Disease Incidence and Carrier Estimation Algorithm (BOADICEA)/CanRisk • BRCAPRO Model	40**
Personal history of radiation therapy when younger than age 30:	

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

High-Risk Indications	Age at which screening can start**
Radiation to chest, whole lung, mediastinum, axilla, mantle (including mini mantle or extended mantle), total or subtotal lymphoid irradiation or total body irradiation (TBI)	25 or 8 years after completion of radiation therapy *whichever comes later*
Breast Density:	
Heterogeneously Dense Breasts (Category C) or Extremely Dense Breasts (Category D) with no additional risk factors	40

*The following have unknown or insufficient evidence of breast cancer risk and additional MRI screening is NOT medically necessary at this time: MSH2, MLH1, MSH6, PMS2, EPCAM, NBN, genetic variants of unknown significance, genetic variants favoring polymorphism, and genetic variants of intermediate penetrance. Any gene mutation not specified in the table above has not currently been found to have sufficient evidence to support surveillance with MRI.

OR 10 years prior to the age of diagnosis of the earliest relative with breast cancer (first-, second-, and third-degree relatives) *whichever comes first*, **but not before age 25

Other Alternative Breast Imaging Techniques

Other alternative breast imaging techniques may have FDA approval, but they remain investigational with respect to **BOTH** screening and diagnosis of breast cancer. These include the following:

- Nuclear breast imaging, including:
  - Scintimammography
  - Breast specific gamma imaging (BSGI)
- PET Mammography (PEM)
- Thermography
- Impedance Mammography
- Other techniques to detect oxygen consumption, light absorption, microwave transmission, nitrous oxide production
- CT Breast (CPT® 0633T, CPT® 0634T, CPT® 0635T, CPT® 0636T, CPT® 0637T, or CPT® 0638T)
- Cone Beam CT Breast

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Background and Supporting Information

- CT Breast
  - CT Breast is evolving and currently being studied as a mode of breast cancer detection. It remains under investigation, and is not to be used in lieu of conventional breast imaging modalities.
- Positron-Emission Mammography
  - There is currently insufficient data available to generate appropriateness criteria for this modality, and this procedure should be considered investigational at this time.
    - High-resolution positron-emission mammography (PEM) by Naviscan™ PET Systems, also referred to as Naviscan™ or PET mammography, performs high-resolution metabolic imaging for breast cancer using an FDG tracer. The PEM detectors are integrated into a conventional mammography system, allowing acquisition of the emission images immediately after the mammogram.
    - Requesting providers often ask for PEM as CPT® 78811 or "PET scan of the breast."
    - The spatial resolution of this technique is at the individual duct level (1.5 mm) and allows visualization of intraductal as well as invasive breast cancers. This technique is especially adept at detecting ductal carcinoma in situ.
    - Early clinical trials have shown high clinical accuracy in characterizing lesions identified as suspicious on conventional imaging or physical examination, as well as in detecting incidental breast cancers not seen on other imaging modalities.
    - A prospective multi-center clinical trial for females with newly diagnosed breast cancer anticipating breast-conservation surgery was performed. These females underwent both high-resolution PEM imaging and breast MRI. Results showed that PEM and MRI had comparable breast-level sensitivity, although MRI had greater lesion-level sensitivity and more accurately depicted the need for mastectomy. PEM had greater specificity at the breast and lesion levels. Of these, 3.6% of the females had tumors seen only with PEM.
    - The radiation exposure from a PEM study is 23 times higher than for digital mammography.

Evidence Discussion

There is limited data regarding the use of MBI in individuals of average breast cancer risk. However, in those classified as high risk (lifetime risk ≥ 20%), the NCCN guideline supported MBI for those who met criteria for supplemental breast MRI, but who could not undergo MRI.[7]

There is no data to support other alternative breast imaging techniques. They are not supported for screening by the ACR, NCCN, or other breast society guidelines. As more data becomes available, the guidelines will be updated accordingly.

Click Here to Return to the Main TOC

The ACS considers individuals who have a first-degree relative with a BRCA 1 or 2 gene mutation and who have not been tested themselves to be at high risk. They recommended an annual MRI screening starting at age 30.[6] On the other hand, NCCN guidelines suggested that untested individuals with a first-degree relative with a BRCA 1 or 2 mutation should start screening either 10 years before the youngest family member was diagnosed with breast cancer, but not before age 25, or at age 40, whichever comes first.[7]

Breast Imaging in Males (BR-9.1)

BR.MA.0009.1.A
v2.0.2026

See **Breast Ultrasound (BR-1)**

Screening for Males at Increased Risk for Breast Cancer

- A clinical breast exam every 12 months is medically necessary.
- Annual mammogram, especially for those with *BRCA2* P/LP variants in whom the lifetime risk of breast cancer is up to 7%, starting at age 50 or 10 years before the earliest known male breast cancer in the family, is medically necessary.
  - MRI of the male breast is not medically necessary given the paucity of evidence supporting its efficacy in male breast disease.

Symptomatic Male Breast Imaging

- Diagnostic Mammogram and/or breast ultrasound (CPT® 76641 or CPT® 76642) is medically necessary for evaluation of the symptomatic male breast and the preferred method depends on age and the suspected etiology of disease.
  - MRI of the male breast is not medically necessary given the paucity of evidence supporting its efficacy in male breast disease.

Background and Supporting Information

- Breast cancer in males presents as a mass, skin/nipple change, or pathologic nipple discharge.

Evidence Discussion

Breast cancer management in cis-gender males is similar to females. NCCN guidelines recommended that, for males presenting with bilateral breast enlargement consistent with gynecomastia or pseudogynecomastia, reassurance with clinical management of the presumed cause (e.g., drug induced, hypogonadism, hyperthyroidism, etc) is all that was needed. For males presenting with palpable symptoms not explained by gynecomastia, or for those presenting with bloody nipple discharge, work up should include mammography and ultrasound, followed by core needle biopsy if these studies should be found to be BIRADS™ category 4-5.[7] Mammography has been found to be accurate in distinguishing benign from malignant lesions in men, and has a sensitivity and specificity of 92% and 90%, respectively, such that more advanced imaging is generally not required.[27]

The NCCN noted support of annual mammogram for cis-gender males, noting it is especially recommended in those "with *BRCA2* P/LP variants in whom the lifetime risk of

Breast Evaluation in Pregnant or Lactating Females (BR-10.1)

BR.PR.0010.1.A

v2.0.2026

- Breast ultrasound (CPT® 76641 or CPT® 76642) is first-line imaging in pregnant and lactating females.
- If pregnant/lactating female has a palpable mass **OR** has persistent unilateral bloody nipple discharge and the ultrasound is negative or suspicious, follow with diagnostic mammogram (with lead abdominal shielding).
- IV Gadolinium is required with MRI to evaluate breast parenchyma but is contraindicated in pregnancy. Biopsy, rather than advanced imaging, is recommended after inconclusive mammogram and ultrasound.
- MRI Breast Bilateral without and with contrast (CPT® 77049 or HCPCS C8908) is supported for evaluation in lactating women if criteria are met otherwise (see **BR-5.1**).
- For imaging requests related to a breast abscess, please see **Breast Pain (Mastodynia) (BR-7.1)**.

Evidence Discussion

Pregnancy-associated breast cancer (PABC) is defined as breast cancer diagnosed during pregnancy, throughout the first postpartum year, or during lactation.

The most common presentation of PABC is a palpable mass, but >80% of palpable masses that are biopsied in pregnant and breastfeeding women are benign.[80]

Given the difficulty examining the pregnant and lactating individual, diagnostic breast imaging is crucial in characterizing the features of a palpable mass. In up to 20% of lactating women, isolated bloody nipple discharge without an associated mass can occur, most commonly due to benign etiologies. However, if persistent, bloody nipple discharge can also be a sign of breast cancer. Diagnostic imaging is also recommended in these women.

Ultrasound has the highest sensitivity for the diagnosis of PABC.[81,82] Additionally, both pregnant and lactating woman are predominantly young and have dense breast tissue. Therefore the sensitivity of mammography decreases in these women. For that reason, ultrasound is the first-line imaging in pregnant and lactating women.[82]

Advanced imaging with breast MRI has a limited role in pregnant women. The IV administration of gadolinium is contraindicated. If there is clinical suspicion of malignancy, a biopsy is the next step in evaluation.[61,83]

Transgender Breast Cancer Supplemental Screening (BR-12.1)

BR.TS.0012.1.A
v2.0.2026

- Annual supplemental breast ultrasound (CPT® 76641 or CPT® 76642) **AND/OR** MRI Breast Bilateral without and with contrast (CPT® 77049 or HCPCS C8908) screening is medically necessary for the following:
  - Transmasculine (female-to-male) with **ALL** of the following risk factors:
    - Reduction mammoplasty or no chest surgery
    - Age ≥25
    - High-risk (≥20% lifetime risk)
- Annual breast ultrasound and/or MRI Breast, in addition to mammogram, for breast cancer screening is **NOT** medically necessary in any other scenarios, including **ANY** of the following:
  - Transfeminine (male-to-female)
  - Transmasculine (female-to-male), who have had bilateral mastectomies
  - Transmasculine (female-to-male), who have **NOT** had mastectomies **AND** are at average risk or intermediate risk
- Acceptable models of calculating clinical lifetime-risk include the following: Gail (NCI), Tyrer-Cuzick (IBIS), The Breast Cancer Surveillance Consortium (BCSC), Breast and Ovarian Analysis of Disease Incidence and Carrier Estimation Algorithm (BOADICEA)/CanRisk, or BRCAPRO.

Evidence Discussion

A number of studies have found that transgender individuals who have transitioned from female to male have the same risk of developing breast cancer as their cis-gendered female counterparts.[28-30] As such, those who still have breast tissue (i.e., have only undergone reduction mammoplasty or no chest surgery), should be screened similarly to cis-gendered women.

The ACR Appropriateness Criteria® recommend the use of ultrasound and/or MRI for individuals who are at intermediate to high risk based on either having a lifetime risk ≥ 20%, a personal history of breast cancer, lobular neoplasia or atypia, chest wall irradiation, or have a genetic predisposition to developing breast cancer.[30] The ACR, does however, recommend transmasculine (female-to-male) individuals start screening earlier than their cis-gendered counterparts (starting at 25-30 years of age).[30]

For transmasculine individuals who are at low to average risk, mammography alone is sufficient.[28-30] Individuals who have had bilateral mastectomies have minimal

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

residual breast tissue, such that breast cancer screening using imaging is not medically necessary.[28-30]

The ACR found insufficient evidence to support the use of routine MRI screening in transfeminine (male-to-female) individuals, regardless of duration of hormone use and/or genetic factors. Transfeminine individuals who would otherwise be considered "high risk" based on personal or family history may consider annual mammography. Similaraly, mammography may be appropriate in transfeminine individuals who have taken feminizing hormones for more than 5 years.[30]

Breast Mass (BR-14)

Guideline

Breast Mass (BR-14.1)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Breast Mass (BR-14.1)

BR.MS.0014.1.A

v2.0.2026

- MRI Breast is **NOT** medically necessary to determine biopsy recommendations for suspicious or indeterminate lesion(s) that can be readily biopsied on physical exam, such as palpable masses.
- For individuals 30 years old and older, diagnostic mammogram and breast ultrasound (CPT® 76641 or CPT® 76642) are medically necessary as the initial imaging.
  - If the breast ultrasound or diagnostic mammogram is a BI-RADS™ category 4 or 5, a Breast MRI is NOT medically necessary. Biopsy is recommended in these circumstances.
- For individuals less than 30 years old, breast ultrasound (CPT® 76641 or CPT® 76642) is medically necessary as the initial imaging.
  - If the breast ultrasound or diagnostic mammogram is a BI-RADS™ category 4 or 5, a Breast MRI is NOT medically necessary. Biopsy is recommended in these circumstances.

Evidence Discussion

According to the ACR Appropriateness Criteria® for "Palpable Breast Masses" there is a paucity of evidence to support the use of MRI Breast in the evaluation of a palpable mass regardless of what the BI-RADS™ is on mammogram.[93]

NCCN guidance for imaging of a palpable breast mass supports the use of diagnostic mammogram and/or ultrasound (preferred modality is dependent on age).[7]

Imaging with BI-RADS™ assessment of category 4 require biopsy. MRI is not supported prior to biopsy.[17]

Imaging with BI-RADS™ assessment of category 3 require short-term follow up imaging: at 6, 12, and 24 months.[18]

Skin Changes (BR-15.1)

BR.SC.0015.1.A

v2.0.2026

- Diagnostic mammogram with or without breast ultrasound (CPT® 76641 or CPT® 76642) is the medically necessary initial imaging.
  - If the diagnostic mammogram or breast ultrasound (if performed) is a BI-RADS™ category 1-3, a MRI Breast Bilateral without and with contrast (CPT® 77049 or HCPCS C8908) is medically necessary.
  - If the diagnostic mammogram or breast ultrasound (if performed) is a BI-RADS™ category 4 or 5, a MRI Breast is NOT medically necessary. Biopsy is recommended in these circumstances.
    - If a core needle biopsy is performed and is benign, a MRI Breast Bilateral without and with contrast (CPT® 77049 or HCPCS C8908) is medically necessary.
- Advanced imaging is **NOT** medically necessary in individuals with breast abscesses.

Evidence Discussion

NCCN guidance for imaging of skin changes of the breast supports the use of diagnostic mammogram with or without breast ultrasound as the initial imaging. Additional imaging with MRI Breast is appropriate for BI-RADS™ 1, 2, or 3 on the initial imaging.[7]

Proprietary Information of UnitedHealthcare.

Nipple Inversion/Retraction (BR-16.1)

BR.NI.0016.1.A
v2.0.2026

This guideline is only to be used when there is no palpable mass. If there is an associated palpable mass, please see **Palpable Mass (BR-14.1)**.

Congenital/Life-Long

- If there are no recent changes, only standard screening is recommended.
- If there are recent changes, see Acquired/New Onset below.

Acquired/New Onset

- If nipple discharge is present, please see **Nipple Discharge/Galactorrhea (BR-6.1)**.
- If skin changes are present, please see **Skin Changes (BR-15.1)**.
- For individuals 30 years old and older, diagnostic mammogram and breast ultrasound (CPT® 76641 or CPT® 76642) are medically necessary for the initial imaging.
  - If the breast ultrasound or diagnostic mammogram is a BI-RADS™ category 1, 2, or 3, but is clinically suspicious, a MRI Breast Bilateral without and with contrast (CPT® 77049 or HCPCS C8908) is medically necessary.
  - If the breast ultrasound or diagnostic mammogram is a BI-RADS™ category 4 or 5, a Breast MRI is NOT medically necessary. Biopsy is recommended in these circumstances.
- For individuals less than 30 years old, breast ultrasound (CPT® 76641 or CPT® 76642) with or without diagnostic mammogram is medically necessary for the initial imaging.
  - If the breast ultrasound or diagnostic mammogram is a BI-RADS™ category 1, 2, or 3, but is clinically suspicious, a MRI Breast Bilateral without and with (CPT® 77049 or HCPCS C8908) is medically necessary.
  - If the breast ultrasound or diagnostic mammogram is a BI-RADS™ category 4 or 5, a Breast MRI is NOT medically necessary. Biopsy is recommended in these circumstances.

Evidence Discussion

NCCN guidance for imaging of nipple inversion/retraction supports the use of diagnostic mammogram and/or breast ultrasound as the initial imaging (preferred modality is dependent on age). Additional imaging with MRI Breast is dependent on the BI-RADS™ category of the initial imaging as well as level of clinical suspicion.[7]

Malignant Phyllodes Tumor/Cystosarcoma Phyllodes (BR-17)

Guideline

Malignant Phyllodes Tumor/Cystosarcoma Phyllodes (BR-17.1)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Malignant Phyllodes Tumor/ Cystosarcoma Phyllodes (BR-17.1)

BR.PT.0017.1.A

v2.0.2026

- MRI Breast Bilateral without and with contrast (CPT® 77049 or HCPCS C8908) is medically necessary pre-operatively to establish extent of disease where a diagnosis of malignant phyllodes tumor has previously been established by tissue diagnosis.

Background and Supporting Information

- Phyllodes tumor is usually benign and has clinical characteristics of fibroadenoma, although they may exhibit rapid growth. MRI Breast has not been shown to be of value in distinguishing fibroadenoma from phyllodes tumor.
- Diagnosis is made by tissue diagnosis (percutaneous core biopsy or excisional biopsy). FNA biopsy is inaccurate in phyllodes tumor diagnosis and is not recommended.
- Treatment is wide local excision. Axillary lymph node dissection is not necessary. It has a predilection for local recurrence following local excision.
- If biopsy establishes a diagnosis of **malignant phyllodes** (cystosarcoma phyllodes), it should be treated as a soft tissue sarcoma. See **Sarcomas – Bone, Soft Tissue, and GIST (ONC-12)** in the Oncology Imaging Guidelines.

Evidence Discussion

Phyllodes tumors of the breast are usually benign, fibroepithelial lesions that have a range of biologic behaviors. Diagnosis is made by percutaneous core biopsy or excisional biopsy. MRI Breast has not been shown to be of value in distinguishing phyllodes tumor from fibroadenoma. However, malignant phyllodes have the propensity to metastasize. Thus, MRI is supported in malignant phyllodes to determine the extent of disease and resectability.[12]

General Information

v2.0.2026

Abbreviations for the Cardiac Imaging Guidelines

Abbreviation	Description
ACC	American College of Cardiology
ACS	Acute coronary syndrome
AHA	American Heart Association
ANOCA	Angina with no obstructive coronary artery disease
ASCOT	Anglo-Scandinavian Cardiac Outcomes Trial
ASD	Atrial septal defect
BMI	Body mass index
CABG	Coronary artery bypass grafting
CAC	Coronary artery calcium
CAD	Coronary artery disease
CAD-RADS 2	The Coronary Artery Disease Reporting and Data System
CHF	Congestive heart failure
CMD	Coronary microvascular dysfunction
COPD	Chronic obstructive pulmonary disease
CT	Computed tomography
CCTA	Coronary computed tomography angiography
CTA	Computed tomography angiography

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Abbreviation	Description
CTV	Computed tomography venography
CV	Cardiovascular
EBCT	Electron beam computed tomography
ECP	External counterpulsation (also known as EECP)
ECG	Electrocardiogram
ECP	External counterpulsation
ETT	Exercise treadmill stress test
FDG	Fluorodeoxyglucose, a radiopharmaceutical used to measure myocardial metabolism
FFR	Fractional flow reserve
HCM	Hypertrophic cardiomyopathy
INOCA	Ischemia with no obstructive coronary artery disease
IV	Intravenous
LAD	Left anterior descending coronary artery
LDL-C	Low density lipoprotein cholesterol
LHC	Left heart catheterization
LV	Left ventricle
LVEF	Left ventricular ejection fraction
MI	Myocardial infarction
MINOCA	Myocardial infarction with no obstructive coronary artery disease
MPI	Myocardial perfusion imaging (SPECT study, nuclear cardiac study)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Abbreviation	Description
MRA	Magnetic resonance angiography
MRI	Magnetic resonance imaging
mSv	millisievert (a unit of radiation exposure) equal to an effective dose of a joule of energy per kilogram of recipient mass
MUGA	Multi gated acquisition scan of the cardiac blood pool
PCI	Percutaneous coronary intervention (includes percutaneous coronary angioplasty (PTCA) and coronary artery stenting)
PET	Positron emission tomography
PTCA	Percutaneous coronary angioplasty
RHC	Right heart catheterization
SCAD	Spontaneous coronary artery dissection
SPECT	Single photon emission computed tomography
TEE	Transesophageal echocardiogram
TAVI	Transcatheter aortic valve implantation
TAVR	Transcatheter aortic valve replacement
TIA	Transient Ischemic Attack
VSD	Ventricular septal defect

Glossary

Acute Chest pain — Chest pain is new onset (<2 mo) or involves a change in pattern, intensity, or duration compared with previous episodes in an individual with recurrent symptoms

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Acute Coronary Syndrome (ACS)	ACS (unstable angina, STEMI and NSTEMI) - sudden imbalance between myocardial oxygen consumption and demand, usually related to coronary artery obstruction, but includes other non-coronary artery origins such as acute coronary insufficiency (e.g., coronary embolism), hypotension, non-ischemic myocardial injury (e.g., myocarditis) and multifactorial causes that are not mutually exclusive (e.g., stress cardiomyopathy)
Adverse Pregnancy Outcomes (APO)	Adverse pregnancy outcomes (APOs) include myriad maternal or fetal complications, including hypertensive disorders of pregnancy (gestational hypertension, preeclampsia, eclampsia, and HELLP [hemolysis, elevated liver enzymes, low platelets] syndrome), placental abruption, spontaneous preterm birth, fetal growth restriction, and small-for-gestational-age infant
Agatston Score	A nationally recognized calcium score for the coronary arteries based on Hounsfield units and size (area) of the coronary calcium
Angina pectoris	Retrosternal chest discomfort that builds gradually in intensity (over several minutes), is usually precipitated by stress (physical or emotional) or occurring at rest (as in the case of an ACS) with characteristic radiation (e.g., left arm, neck, jaw) and its associated symptoms (e.g., dyspnea, nausea, lightheadedness). When actively treated (e.g., nitroglycerin) or spontaneously resolving (e.g., with rest), it dissipates over a few minutes
Anginal variants or equivalents	Symptoms or pain at a site other than the chest occurring in an individual at high cardiac risk (i.e., known CAD, diabetes). Anginal equivalents have the same importance as angina pectoris and can present as dyspnea, diaphoresis, nausea, extreme fatigue, pain, pressure, tightness, or discomfort in shoulders, arms, neck, back, upper abdomen, or jaw not otherwise explained by another process.
ARVD/ARVC – Arrhythmogenic Right	A potentially lethal inherited disease with syncope and rhythm disturbances, including sudden death, as presenting manifestations

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Ventricular Dysplasia/ Cardiomyopathy	
BNP	B-type natriuretic peptide, blood test used to diagnose and track heart failure (n-T-pro-BNP is a variant of this test)
Brugada Syndrome	An electrocardiographic pattern that is unique and might be a marker for significant life-threatening dysrhythmias
Chronic Coronary Syndrome	CAD that is chronic, often progressive, and is treatable with lifestyle adjustments, medications, and invasive interventions instituted to achieve disease stabilization or regression
Double Product (Rate Pressure Product)	An index of cardiac oxygen consumption, is the systolic blood pressure times heart rate, generally calculated at peak exercise; over 25000 means an adequate stress load was performed
Fabry Disease	An infiltrative cardiomyopathy, can cause heart failure and arrhythmias
Fatigue	A subjective feeling of weakness, tiredness or exhaustion. Exertional fatigue is acute in nature, with rapid onset, short duration, and short recovery period.
Hibernating myocardium	Viable but poorly functioning or non-functioning myocardium which likely could benefit from intervention to improve myocardial blood supply
Optimized Medical Therapy	Should include (where tolerated) antiplatelet agents, calcium channel antagonists, partial fatty acid oxidase inhibitors (e.g., ranolazine), statins, short-acting nitrates as needed, long-acting nitrates up to 6 months after an acute coronary syndrome episode, beta blocker drugs (optional), angiotensin-converting enzyme (ACE) inhibitors/angiotensin receptor blocking (ARB) agents (optional)
Platypnea	Shortness of breath when upright or seated (the opposite of orthopnea) and can indicate cardiac malformations, shunt or tumor

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Risk factors for Cardiac Chest pain	Comorbidities that increase the risk of developing coronary artery disease such as age ≥65 y, diabetes, hypertension (i.e., stage 1 hypertension (130–139mm Hg systolic or 80–89mm Hg diastolic), or stage 2 hypertension (≥140mm Hg systolic or ≥90mm Hg diastolic), adverse pregnancy outcomes, family history of premature CAD (history of any direct blood relatives [parents, siblings, children]) who have had any of the following conditions at age 55 or younger for male relatives or age 65 or younger for female relatives: AMI, sudden cardiac death without obvious cause, CABG surgery, PCI, familial/genetic factors (includes genetic abnormalities leading to vasculopathies, aneurysmal disorders, cardiomyopathies, coagulopathies, and inherited dysrhythmia syndromes)
Silent ischemia	Absence of ischemic symptoms or signs prior to objective demonstration of ischemia by stress testing and/or demonstration of obstructive CAD
Stable Chest Pain	Chest pain symptoms are chronic (≥2 mo) and associated with consistent precipitants such as exertion or emotional stress
Syncope	Loss of consciousness; near-syncope is not syncope
Takotsubo cardiomyopathy	Apical dyskinesis oftentimes associated with extreme stress and usually thought to be reversible
Troponin	A marker for ischemic injury, primarily cardiac
TAVR (TAVI)	A minimally invasive procedure to treat aortic valve disease

General Guidelines (CD-1.0)

CD.GG.0001.0.A
v2.0.2026

General Guidelines

- A pertinent clinical evaluation since the onset or change in symptoms is required prior to considering advanced imaging, which includes:
  - Relevant history and physical examination and appropriate laboratory studies and non-advanced imaging modalities, such as recent ECG, chest x-ray or ECHO/ ultrasound, performed after symptoms started or worsened
    - Effort should be made to obtain copies of reported abnormal ECG studies in order to determine whether the ECG is uninterpretable for ischemia on ETT.
    - Most recent previous stress testing and its findings should be obtained.
  - A relevant clinical evaluation documenting any subjective findings (complaints, changes in behavior) or objective findings (clinical exam findings)
    - Other meaningful contact (telephone call, electronic mail or messaging) by an established individual can substitute for a face-to-face clinical evaluation such as requests based on new increased or worsening symptoms.
    - Some conditions may require a face-to-face evaluation as discussed in the applicable condition-specific guideline sections (such as requests based on new physical exam findings).
    - A clinical evaluation may be medically unnecessary if the individual is undergoing a guideline-supported, scheduled follow-up imaging or other designated procedural evaluation.
    - Exceptions due to routine surveillance indications are addressed in the applicable condition-specific guideline sections.
  - Vital signs, height and weight, BMI, or description of general habitus is needed.
  - Clinical question to be answered by advanced imaging that will affect management of the individual's clinical condition
- Cardiac imaging is not medically necessary if the results will not affect clinical management decisions. If a decision to perform cardiac catheterization or other angiography has already been made, there is often no need for imaging stress testing.
- Assessment of ischemic symptoms (if present) based on the descriptions below following this section

Proprietary Information of UnitedHealthcare.

Cardiac evaluation

Cardiac Chest Pain (likely angina)

For the purpose of this guideline, when diagnostic testing is requested to evaluate cardiac symptoms for suspected ischemic origin, chest pain is defined as follows:

- Cardiac chest pain (stable angina pectoris, typical angina, likely angina) is defined as **one** of the following:
  - Retrosternal chest discomfort described as pain, pressure, squeezing, heaviness, tightness, or burning, and may radiate to the left arm, neck, jaw, or back that is precipitated by exercise or stress and resolved with rest or nitroglycerin
  - In an individual with known CAD (history of myocardial infarction, prior coronary revascularization with PCI or CABG, imaging or testing showing obstructive CAD) or SCAD (spontaneous coronary artery dissection) with any of the following symptoms:
    - chest discomfort
    - unexplained exertional fatigue
    - unexplained dyspnea on exertion
    - an individual's known anginal equivalent (symptoms with prior known cardiac event)
  - Retrosternal chest discomfort described as pain, pressure, squeezing, heaviness, tightness, or burning, and may radiate to the left arm, neck, jaw, or back that is precipitated by exercise or stress is considered cardiac chest pain in the setting of any of the following:
    - age ≥65
    - diabetes mellitus
    - hypertension
    - history of adverse pregnancy outcomes
    - chest pain associated with syncope
    - family history of premature CAD (occurring before age 56 in males or before age 66 in females)
- Possible Cardiac Chest Pain (less likely angina, possible angina. atypical chest pain):
  - Symptoms suggestive of a cardiac origin but lacking definitive features or occurring in a time course not suggestive of angina (such as atypical pain location or quality, pain resolves spontaneously within seconds or lasts for an extended period and is unrelated to exertion)
  - May occur in the presence of mild associated symptoms, or in the presence of some risk factors without diagnostic confirmation
- Non-cardiac explanation:
  - Pain likely due to non-cardiac causes, especially when persistent or recurring despite negative cardiac evaluations

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - Pain qualities include sharp, stabbing, fleeting, or positional. Associated symptoms may include heartburn unrelated to meals or abdominal discomfort.
- Anginal equivalents (individuals with previously documented CAD only):
  - Symptoms consistent with individual's known angina pattern in an individual with a history of CABG or PCI
  - Dyspnea on exertion
  - Fatigue (overwhelming sense of unexplained exhaustion causing a decreased capacity for physical activity or mental work)

Other signs and symptoms suggestive of potential cardiac etiology:
- dyspnea
- orthopnea
- paroxysmal nocturnal dyspnea
- heartburn unrelated to meals/nausea and vomiting
- palpitations
- syncope
- heart failure

Note: Chest pain remains the predominant symptom reported by females among those diagnosed with an acute coronary syndrome.

For the purpose of this guideline, evidence documenting the presence of obstructive CAD includes any of the following:
- Prior heart catheterization or CCTA revealing any of the following:
  - ≥40% stenosis of the left main coronary artery
  - ≥50% stenosis for other major epicardial vessels
  - Significant stenosis defined by an FFR of ≤0.80
  - History of a prior PCI or CABG

For the purpose of this guideline, evidence documenting the presence of non-obstructive CAD includes prior heart catheterization or CCTA revealing any of the following:
- <40% stenosis of the left main coronary artery
- <50% stenosis for other major epicardial vessels
- FFR >0.8

The Coronary Artery Disease Reporting and Data System (CAD-RADS 2) classification of percentage luminal diameter coronary artery stenosis on coronary CT angiography (CCTA) is as follows:
- CAD-RADS 0: 0%
- CAD-RADS 1: 1% to 24%
- CAD-RADS 2: 25% to 49%
- CAD-RADS 3: 50% to 69%

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- CAD-RADS 4:
  - ≥50% left main coronary artery stenosis
  - ≥70% in at least one major coronary artery
- CAD-RADS 5: 100% (total occlusion)

For the purposes of this guideline, evidence documenting a prior MI includes any of the following:

- presence of diagnostic Q waves on an ECG
- a fixed perfusion defect on MPI
- akinetic or dyskinetic wall motion on echocardiogram
- area of Late Gadolinium Enhancement (LGE) on cardiac MRI suggesting scar

Findings that may alter the ECG changes during exercise or are uninterpretable for ischemia on a stress test:

- Complete Left Bundle Branch Block (bifasicular block involving right bundle branch and left anterior hemiblock does not render ECG uninterpretable for ischemia)
- Ventricular paced rhythm
- Pre-excitation pattern such as Wolff-Parkinson-White
- ≥1.0mm ST segment depression (NOT nonspecific ST/T wave changes)
- LVH with repolarization abnormalities, also called LVH with strain (NOT without repolarization abnormalities or by voltage criteria)
- T wave inversion in at least two contiguous inferior and/or lateral leads. This includes leads I, II, AVF, AVL, V5 or V6. (T wave inversion isolated in lead III or T wave inversion in lead V1 and V2 are not included).
- Individual on digitalis preparation

The Exercise Treadmill Test (ETT)

- Requirements for a diagnostic ETT include:
  - ECG that can be interpreted for ischemia.
  - Individual capable of exercise to achieve target heart rate on a treadmill or similar device (5 METs or greater; see functional capacity below). Target heart rate is calculated as 85% of the maximum age predicted heart rate (MPHR). MPHR is estimated as 220 minus the individual's age.
- An abnormal ETT (exercise treadmill test) includes at least one of the following:
  - ST segment depression (horizontal or downsloping, ≥1.0 mm below baseline)
  - Development of chest pain
  - Drop in systolic blood pressure >10 mmHg during exercise
  - Non-sustained ventricular tachycardia ≥3 consecutive ventricular beats at a rate of >100 beats per minute

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Sustained ventricular tachycardia (ventricular rhythm at rate >100 beats/minute lasting >30 seconds or requiring termination due to hemodynamic compromise in <30 seconds)

- Functional capacity ≥5 METs equates to the following:
  - Can walk four blocks without stopping
  - Can walk up a hill
  - Can climb one flight of stairs without stopping
  - Can perform heavy work around the house
  - Can walk 4 mph at a brisk pace

Evidence Discussion

Chest pain

Many factors are taken into consideration when an individual presents chest pain or symptoms suspect for an underlying cardiac etiology, such as coronary artery disease or congestive heart failure. Details such as precipitating and alleviating factors, duration of the symptoms, chronicity, progression, and prior medical history or risk factors that may escalate the concern for ischemia. Symptoms associated with cardiac etiology can include chest pain, pressure, heaviness, tightness, dyspnea, diaphoresis, nausea/vomiting, lightheadedness, syncope, and palpitations. Cardiac pain related to ischemia is characterized by pressure, squeezing, heaviness, tightness, or burning in the chest, often retrosternal, and radiating to the left arm, neck, jaw, or back. In general, ischemic chest pain has a gradual onset over minutes, is relieved by rest or nitroglycerin, and is precipitated by exertion or emotional stress.[1] Risk factors increasing the likelihood of an ischemic etiology of chest pain include age ≥65, diabetes, hypertension, history of adverse pregnancy outcomes, chest pain associated with syncope, family history of premature CAD, and genetic predispositions.[2,3]

CAD RADS 2

Coronary Artery Disease – Reporting and Data System (CAD-RADS 2)[4] is a standardized reporting framework for coronary CT angiography (CCTA) results designed to improve communication and guide clinical management. Classification includes stenosis severity (0–5), plaque burden (P1–P4), and modifiers (e.g., HRP,

Click Here to Return to the Main TOC

I, S, G, E) for CT-FFR and myocardial CT perfusion for ischemia assessment and is applicable to both stable and acute chest pain evaluations.[5] [6]

Background and Supporting Information

An observational study found that, compared with the Duke Activity Status Index, subjective assessment by clinicians generally underestimated exercise capacity

Upsloping ST segment depression is not considered to be an abnormal ETT finding because of its low specificity.

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

Stress Testing with Imaging (CD-1.4)

CD.ST.0001.4.A
v2.0.2026

General information

- Imaging Stress Tests include any one of the following:
  - Stress Echocardiography
  - SPECT MPI
  - Stress perfusion MRI may include AQMBF
  - PET Perfusion may include AQMBF
- Stress testing with imaging can be performed with maximal exercise or chemical stress (adenosine, dipyridamole, dobutamine, or regadenoson) and does not alter the CPT® codes used to report these studies.

Absolute quantitation of myocardial blood flow (AQMBF) PET or MRI

CPT® 78434 AQMBF PET or CPT® 0899T or 0900T AQMBF MRI

AQMBF is medically necessary to further evaluate cardiac function when included with cardiac PET perfusion or a cardiac MRI stress perfusion

Stress Testing with Imaging-Coding

Stress echo, SPECT MPI or stress MRI

CPT®	Codes Addressed
Stress MRI	
75559	Cardiac MRI for morphology and function without contrast, with stress imaging
75563	Cardiac MRI for morphology and function without and with contrast, with stress imaging

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

CPT®	Codes Addressed
+0899T	Noninvasive determination of absolute quantitation of myocardial blood flow (AQMBF), derived by augmentative algorithmic analysis of the dataset acquired via contrast cardiac magnetic resonance (CMR), pharmacologic stress, with interpretation and report by a physician or other qualified health care professional (List separately in addition to code for primary procedure)
+0900T	Noninvasive estimate of absolute quantitation of myocardial blood flow (AQMBF), derived by assistive algorithmic analysis of the dataset acquired via contrast cardiac magnetic resonance (CMR), pharmacologic stress, with interpretation and report by a physician or other qualified health care professional (List separately in addition to code for primary procedure).
MPI SPECT	
78451	MPI, tomographic (SPECT) including attenuation correction, qualitative or quantitative wall motion, ejection fraction by first pass or gated technique, additional quantification, when performed); single study, at rest or stress (exercise or pharmacologic)
78452	MPI, tomographic (SPECT) (including attenuation correction, qualitative or quantitative wall motion, ejection fraction by first pass or gated technique, additional quantification, when performed); multiple studies, at rest and/or stress (exercise or pharmacologic) and/or redistribution and/or rest reinjection
78453	Myocardial perfusion imaging, planar (including qualitative or quantitative wall motion, ejection fraction by first pass or gated technique, additional quantification, when performed); single study, at rest or stress (exercise or pharmacologic)
78454	Myocardial perfusion imaging, planar (including qualitative or quantitative wall motion, ejection fraction by first pass or gated technique, additional quantification, when performed); multiple studies, at rest and/or stress (exercise or pharmacologic) and/or redistribution and/or rest reinjection
Stress echocardiogram	
93350	Echocardiography (TTE), (2D), with or without m-mode, during rest and cardiovascular stress, with interpretation and report

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

CPT®	Codes Addressed
93351	Echocardiography (TTE), (2D), m-mode, during rest and cardiovascular stress test using treadmill, bicycle exercise and/or pharmacologically induced stress, with interpretation
	PET MPI
78430	Myocardial imaging, positron emission tomography (PET), perfusion study (including ventricular wall motion[s] and/or ejection fraction[s], when performed); single study, at rest or stress (exercise or pharmacologic), with concurrently acquired computed tomography transmission scan
78431	Myocardial imaging, positron emission tomography (PET), perfusion study (including ventricular wall motion[s] and/ or ejection fraction[s], when performed); multiple studies at rest and stress (exercise or pharmacologic), with concurrently acquired computed tomography transmission scan
78491	Myocardial imaging, positron emission tomography (PET), perfusion study (including ventricular wall motion[s] and/or ejection fraction[s], when performed); single study at rest or stress (exercise or pharmacologic)
78492	Myocardial imaging, positron emission tomography (PET), perfusion study (including ventricular wall motion[s] and/or ejection fraction[s], when performed); multiple studies at rest and stress (exercise or pharmacologic)
+78434	Absolute quantitation of myocardial blood flow (AQMBF), positron emission tomography (PET), rest and pharmacologic stress (List separately in addition to code for primary procedure)

Stress Testing with Imaging-Indications

Stress test with imaging (Stress echo, SPECT MPI, PET MPI, or stress MRI) is considered medically necessary in **any** of the following clinical settings:

Cardiac Chest Pain

New, recurrent or worsening cardiac chest pain as defined in **General Guidelines (CD-1.0)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Symptomatic with known CAD

Prior history of PCI (percutaneous coronary intervention) or CABG (coronary artery bypass graft surgery) or a history of obstructive CAD as defined in **General Guidelines (CD-1.0)** and **any** of the following:

- Cardiac chest pain as defined in **General Guidelines (CD-1.0)**
- Anginal equivalents such as atypical chest pain, exertional dyspnea or exertional fatigue
- Symptoms similar to prior ischemic episode

Newly elevated troponin with known CAD

Prior history of PCI (percutaneous coronary intervention) or CABG (coronary artery bypass graft surgery) or a history of obstructive CAD as defined in **General Guidelines (CD-1.0)** and a new Troponin elevation after last evaluation with stress test, CCTA, or diagnostic cardiac catheterization

Symptomatic and does not meet the requirements for an ETT without imaging

New, recurrent, or worsening symptoms of chest pain, or new, recurrent, or worsening symptoms of exertional dyspnea or exertional fatigue that is not explained by another process, **and** the individual does not meet the medically necessary components needed for an ETT due to a history of **any** of the following:

- Findings that may alter the ECG changes during exercise or are uninterpretable for ischemia on a stress test:
  - Complete Left Bundle Branch Block (bifasicular block involving right bundle branch and left anterior hemiblock does not render ECG uninterpretable for ischemia)
  - Ventricular paced rhythm
  - Pre-excitation pattern such as Wolff-Parkinson-White
  - ≥1.0mm ST segment depression (NOT nonspecific ST/T wave changes)
  - LVH with repolarization abnormalities, also called LVH with strain (NOT without repolarization abnormalities or by voltage criteria)
  - T wave inversion in at least two contiguous inferior and/or lateral leads. This includes leads I, II, AVF, AVL, V5 or V6. (T wave inversion isolated in lead III or T wave inversion in lead V1 and V2 are not included).
  - Individual on digitalis preparation
- Inability to perform the exercise needed to achieve target heart rate (85% of the maximum age predicted heart rate or 220 minus the individual's age) on a treadmill or similar device (5 METs or greater) due to any of the following limitations:
  - Unable to safely perform ETT due to gait disturbances, use of assistive devices, or other documented neuromuscular abnormalities
  - Use of home oxygen for daily activity

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Documented activity-limiting dyspnea or heart failure
- Provider assessment that performing an ETT would be unsafe
- Unstable angina with concern for active acute coronary syndrome, or recent elevated troponin
- Severe aortic stenosis or other significant aortic valve disease
- Severe hypertension that can not be controlled prior to stress testing

Symptomatic with suspected or known non-obstructive CAD
PET MPI with AQMBF or stress cardiac MRI with AQMBF only

Stress imaging with AQMBF is medically necessary for individuals with suspected or known non-obstructive CAD such as MINOCA (myocardial infarction with no obstructive coronary arteries), INOCA (ischemia with no obstructive coronary arteries), or ANOCA (angina with no obstructive coronary arteries) to evaluate persistent symptoms of chest pain, exertional dyspnea, or exertional fatigue in the setting of any of the following:

- a normal or equivocal ETT
- a diagnosis of no obstructive CAD on CCTA or invasive coronary angiography with **either** of the following:
  - persistent symptoms despite medical management (beta-blockers, CCBs, nitrates, ranolazine, and ACE-Is)
  - functional testing demonstrates myocardial ischemia (such as invasive coronary function testing or non-invasive stress testing without AQMBF)

Symptomatic with inconclusive or abnormal ETT or elevated CAC

New, recurrent or worsening symptoms of chest pain, or new, recurrent, or worsening symptoms of exertional dyspnea or exertional fatigue that is not explained by another process, and any of the following:

- Inconclusive ETT (exercise treadmill test) due to any of the following:
  - <85% maximum predicted heart rate achieved
  - Exercise ECG is uninterpretable for ischemia (for example due to development of rate-related left bundle branch block during exercise)
- Abnormal ETT with any of the following results:
  - ST segment depression (horizontal or downsloping, ≥1.0 mm below baseline)
  - Development of chest pain
  - Drop in systolic blood pressure >10 mmHg during exercise
  - Non-sustained ventricular tachycardia ≥3 consecutive ventricular beats at a rate of >100 beats per minute

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - Sustained ventricular tachycardia (ventricular rhythm at rate >100 beats/minute lasting >30 seconds or requiring termination due to hemodynamic compromise in <30 seconds)
- Coronary artery calcium (CAC) score ≥100

Symptomatic with Risk Factors

Stress test with imaging is medically necessary in individuals with **both** of the following conditions:

- New, recurrent or worsening symptoms of chest pain, or new, recurrent, or worsening symptoms of exertional dyspnea or exertional fatigue that is not explained by another process
- Individuals 50 years of age or above with 2 or more of the following CV risk factors:
  - diabetes
  - current cigarette smoking
  - family history of premature CAD
  - hypertension
  - hyperlipidemia
  - history of adverse pregnancy outcomes (APOs)

Heart failure or left ventricular systolic dysfunction

Stress test with imaging is medically necessary to evaluate heart failure or left ventricular systolic dysfunction when there is documentation of **any** of the following:

- New or worsening heart failure
- New left ventricular systolic dysfunction (left ventricular ejection fraction <50%)
- Worsening left ventricular systolic dysfunction (decline in left ventricular ejection fraction ≥10%)
- Significant ischemic ventricular dysfunction (suspected hibernating myocardium) to assess myocardial viability when there are persistent symptoms or heart failure and revascularization is being considered

---

Note:

MRI, cardiac PET, SPECT MPI, or Dobutamine stress echo can be used to assess myocardial viability depending on physician preference. See also **Cardiac PET – Metabolic – Indications (CD-6.4)**

Syncope or arrhythmia

Stress test with imaging is medically necessary for **any** of the following:

- Syncope of suspected ischemic etiology not otherwise explained

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Sustained ventricular tachycardia (ventricular rhythm at rate >100 beats/minute lasting >30 seconds or requiring termination due to hemodynamic compromise in <30 seconds).
- Non-sustained ventricular tachycardia ≥3 consecutive ventricular beats at rate >100 beats/minute
- Frequent PVCs (premature ventricular complexes) >30 PVCs per hour
- Prior to starting a Class IC antiarrhythmic agent (flecainide or propafenone) to assess for CAD and annually while taking the medication

With or without symptoms for moderate coronary artery stenosis

Stress test with imaging is medically necessary to evaluate the functional significance of moderate stenosis when there is documentation of **either** of the following:

- CCTA (coronary computed tomography angiography) with moderate stenosis (50 to 69%-CAD-RADS 3 as defined in **General Guidelines CD-1.0**)
- Invasive coronary angiography with intermediate severity stenosis and invasive physiological testing has not been done

Without symptoms

Stress test with imaging is medically necessary for any of the following:

- Prior to starting Interleukin-2
- An uninterpretable ECG as described in **General Guidelines (CD 1.0)** that has not been previously evaluated
- Every 2 years if there is a history of silent ischemia (absence of ischemic symptoms or signs prior to objective demonstration of ischemia by stress testing and/or demonstration of obstructive CAD as defined in **General Guidelines (CD-1.0)**
- Prior to starting a Class IC antiarrhythmic agent (flecainide or propafenone) to assess for CAD and annually while taking the medication
- Asymptomatic individual who has an ischemic EKG response on ETT (horizontal or downsloping ST depression ≥1.0mm below baseline)

Evidence Discussion

Appropriate Use Criteria from major professional societies including the American College of Cardiology and the American Heart Association support the use of myocardial perfusion imaging (MPI) with single photon emission computed tomography (SPECT) for individuals with signs or symptoms consistent with coronary artery disease (CAD) such as typical angina. In addition, they support the use of SPECT perfusion imaging in symptomatic individuals with known CAD and those with prior interventions such as coronary artery bypass surgery, coronary stenting, and preoperative risk stratification. These guidelines balance the appropriate testing

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

of individuals with SPECT versus unnecessary and potentially harmful testing and downstream procedures.

Also, as supported by society guidelines, use of SPECT is medically necessary in detection of cardiac transthyretin amyloidosis (ATTR) after light chain amyloidosis (AL) is ruled out by appropriate blood and urine testing. Positron emission tomography (PET) is an advanced imaging approach in that it allows for more accurate attenuation correction than SPECT, which can be helpful in individuals with higher BMIs or other sources of attenuation. In addition, due to accurate attenuation correction and the unique attributes of PET radionuclides, PET allows the quantitation of myocardial blood flow and flow reserve which has been shown to be helpful in the diagnosis and prognosis of obstructive and no obstructive CAD.

Stress Testing with Imaging-Preoperative (CD-1.5)

CD.ST.0001.5.A
v2.0.2026

Table-2 Cardiac Risk Stratification List

High-risk (> 5%)	Intermediate-risk (1-5%)	Low-risk (<1%)
• Open aortic and other major open vascular surgery • Open peripheral vascular surgery • Esophagectomy • Pneumonectomy • Open intraperitoneal and/or intrathoracic surgery with organ resection	• Open intraperitoneal and/or intrathoracic surgery without major organ resection • Open carotid endarterectomy • Head and neck surgery • Open orthopedic surgery • Open prostate surgery	• Endoscopic procedures • Superficial procedures • Cataract surgery • Breast surgery • Ambulatory surgery • Laparoscopic and endovascular procedures that are unlikely to require further extensive surgical intervention

- There are **2** steps that determine the need for imaging stress testing in (stable) pre-operative individuals:
  - Step 1: Would the individual qualify for imaging stress testing independent of planned surgery?
    - If yes, proceed to stress testing guidelines **Stress Testing with Imaging – Indications (CD-1.4)**.
    - If no, go to step 2.
  - Step 2: Is the surgery considered high-, moderate-, or low-risk? (see **Table-2**)
    If high- or moderate-risk, proceed below. If low-risk, there is no evidence to determine a need for pre-operative cardiac testing.
    - **High-risk Surgery:** All individuals in this category should receive an imaging stress test if there has not been an imaging stress test within 1 year unless the individual has developed new cardiac symptoms or a new change in the EKG since the last stress test.
    - **Intermediate-risk Surgery:** One or more clinical risk factors and unable to perform an ETT per guidelines if there has not been an imaging stress test within 1 year unless the individual has developed new cardiac symptoms or a new change in the EKG since the last stress test.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

    - **Low-risk:** Pre-operative imaging stress testing is not medically necessary.
  - Clinical Risk Factors (for cardiac death and non-fatal MI at time of non-cardiac surgery)
    - History of ischemic heart disease (previous MI, previous positive stress test, use of nitroglycerin, typical angina, ECG Q waves, previous PCI or CABG)
    - History of compensated previous congestive heart failure (history of heart failure, previous pulmonary edema, third heart sound, bilateral fine crackles, chest x-ray showing heart failure)
    - History of previous TIA or stroke
    - Diabetes Mellitus
    - Creatinine level >2mg/dL

Evidence Discussion

Appropriate Use Criteria from major professional societies including the American College of Cardiology and the American Heart Association support the use of myocardial perfusion imaging (MPI) with single photon emission computed tomography (SPECT) for individuals with signs or symptoms consistent with coronary artery disease (CAD) such as typical angina. In addition, they support the use of SPECT perfusion imaging in symptomatic individuals with known CAD and those with prior interventions such as coronary artery bypass surgery, coronary stenting, and preoperative risk stratification. These guidelines balance the appropriate testing of individuals with SPECT versus medically unnecessary and potentially harmful testing and downstream procedures.

Also, as supported by society guidelines, use of SPECT is medically necessary in detection of cardiac transthyretin amyloidosis (ATTR) after light chain amyloidosis (AL) is ruled out by appropriate blood and urine testing.

Transthoracic Echocardiogram (TTE)-Coding (CD-2.1)

CD.EC.0002.1.A
v2.0.2026

Transthoracic Echocardiography (TTE)-Coding

Transthoracic Echocardiography

Description	CPT®
TTE for congenital cardiac anomalies, complete	93303
TTE for congenital cardiac anomalies, follow-up or limited	93304
TTE with 2-D, M-mode, Doppler and color flow, complete	93306
TTE with 2-D, M-mode, without Doppler or color flow	93307
TTE with 2-D, M-mode, follow-up or limited	93308

3D Echocardiography

Description	CPT®
3D rendering with interpretation and reporting of computed tomography, magnetic resonance imaging, ultrasound, or other tomographic modality with image post-processing under concurrent supervision; not requiring image post-processing on an independent workstation	76376
3D rendering with interpretation and reporting of computed tomography, magnetic resonance imaging, ultrasound, or other tomographic modality with image post-processing under concurrent supervision; requiring image post-processing on an independent workstation	76377

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Description	CPT®
3D echocardiographic imaging and post-processing during transesophageal echocardiography, or during transthoracic echocardiography for congenital cardiac anomalies, for the assessment of cardiac structure(s) (e.g., cardiac chambers and valves, left atrial appendage, interatrial septum, interventricular septum) and function, when performed (List separately in addition to code for echocardiographic imaging) Code with (93303-93304, 93312, 93314, 93315, 93317, 93350-93351)	+93319

Doppler Echocardiography

Description	CPT®
Doppler echo, pulsed wave and/or spectral display	+93320
Doppler echo, pulsed wave and/or spectral display, follow-up or limited study	+93321
Doppler echo, color flow velocity mapping	+93325
CPT® 93320 and CPT® 93321 should not be requested or billed together	

C Codes

C codes are unique temporary codes established by CMS. C codes were established for contrast echocardiography. Each echocardiography C code corresponds to a standard echo code (Class I CPT® code) The C code and the matching CPT code should not both be approved.

C Code	Transthoracic Echocardiography	CPT®
C8921	TTE for congenital cardiac anomalies, complete	93303
C8922	TTE for congenital cardiac anomalies, follow-up or limited	93304
C8929	TTE with 2-D, M-mode, Doppler and color flow, complete	93306
C8923	TTE with 2-D, M-mode, without Doppler or color flow	93307
C8924	TTE with 2-D, M-mode, follow-up or limited	93308

Myocardial strain imaging

Description	CPT®
Myocardial strain imaging using speckle tracking-derived assessment of myocardial mechanics (List separately in addition to codes for echocardiography imaging)	+93356

Investigational codes

Description	CPT®
Myocardial contrast perfusion echocardiography, at rest or with stress, for assessment of myocardial ischemia or viability	0439T
Noninvasive detection of heart failure derived from augmentative analysis of an echocardiogram that demonstrated preserved ejection fraction, with interpretation and report by a physician or other qualified health care professional	0932T

Transthoracic Echocardiography (TTE) – Coding General Information (CD-2.1.1)

- Complete transthoracic echocardiogram with spectral and color flow Doppler (CPT® 93306).
  - 93306 includes the Doppler exams, so CPT® codes 93320-93325 should not be assigned together with CPT® 93306.
  - Doppler codes (CPT® 93320, CPT® 93321, and CPT® 93325) are 'add-on codes' (as denoted by the + sign) and are assigned in addition to code for the primary procedure.
- For a 2D transthoracic echocardiogram without Doppler, report CPT® 93307.
- Limited transthoracic echocardiogram (CPT® 93308) should be billed if the report does not "evaluate or document the attempt to evaluate" all of the required structures.
  - A limited transthoracic echocardiogram is reported with CPT® 93308.
  - CPT® 93321 (not CPT® 93308 if Doppler is included in the study. CPT® 93325 can be reported with CPT® 93308 if color flow Doppler is included in the study.
  - A limited congenital transthoracic echocardiogram is reported with CPT® 93304.
- Doppler echo may be used for evaluation of the following:
  - shortness of breath
  - known or suspected valvular disease
  - known or suspected hypertrophic obstructive cardiomyopathy
  - shunt detection

Background and Supporting Information

- Providers performing echocardiography on a pediatric individual may not know what procedure codes they will be reporting until the initial study is completed.
- If a congenital issue is found on the initial echocardiogram, a complete echocardiogram is reported with codes CPT® 93303, CPT® 93320, and CPT® 93325 because CPT® 93303 does NOT include Doppler and color flow mapping.
- If no congenital issue is discovered, then CPT® 93306 is reported alone and includes 2D, Doppler and color flow mapping.
- Since providers may not know the appropriate code(s) that will be reported at the time of the pre-authorization request, they may request all 4 codes (CPT® 93303, CPT® 93320, CPT® 93325, and CPT® 93306).
- CPT® 76376 and CPT® 76377 are not unique to 3D Echocardiography. These codes also apply to 3D rendering of MRI and CT studies. See **3D Echocardiography – Coding (CD-2.9)**.
- CPT® 93325 may also be used with fetal echocardiography.
- CPT® 93319 3D echocardiography imaging post-processing of TEE or TTE to evaluate congenital cardiac abnormalities. See **3D Echocardiography – Coding (CD-2.9)**.

Myocardial Contrast Perfusion Echocardiography (CD-2.11)

(CPT® 0439T)

- Investigational see **Transthoracic Echocardiography (TTE) – Coding (CD-2.1)**

Detection of Heart Failure with Preserved Ejection Fraction

Noninvasive detection of heart failure derived from augmentative analysis of an echocardiogram

Artificial intelligence (AI) applications are being used to extract patterns from medical images in an effort to add clinically relevant information to that obtained by physician interpretation of images. AI algorithms have been employed in the software analysis of echocardiograms in an effort to aid detection of heart failure. Further studies are needed to evaluate the accuracy, reliability, and clinical efficacy of these applications.

- CPT® 0932T Noninvasive detection of heart failure derived from augmentative analysis of an echocardiogram is considered experimental, investigational, or unproven at this time

Transthoracic Echocardiography (TTE) Indications/Initial Evaluation (CD-2.2)

CD.EC.0002.2.A
v2.0.2026

Transthoracic Echocardiography (TTE) is medically necessary for the initial evaluation of **any** of the following:

Symptoms or signs suggesting cardiovascular disease

- chest pain/discomfort
- dyspnea/shortness of breath, or hypoxemia
- palpitations
- pre-syncope/syncope
- headache with transcranial Doppler evidence of a shunt or high-degree of suspicion for embolic process
- dependent lower extremity edema
- abnormal precordial or peripheral pulse
- new or changing heart murmur or click
- suspected hypertensive heart disease (initial evaluation)
- initial evaluation of known/suspected heart failure based on symptoms and/or signs
- suspected endocarditis with any:
  - fever
  - peripheral stigmata of endocarditis
  - new murmur
- history of rheumatic heart disease
- suspected pericardial diseases
- suspected cardiac injury due to blunt chest trauma

Diagnostic tests suggesting cardiovascular disease

- newly diagnosed RBBB or LBBB
- presence of pathological Q waves in 2 or more contiguous leads
- frequent VPCs defined as occurring more frequently than 30 times per hour or occurring in a pattern of bigeminy, trigeminy, or runs of ventricular tachycardia
- non sustained or sustained ventricular tachycardia (VT)
- ventricular fibrillation (VF)
- newly diagnosed atrial fibrillation/flutter
- cardiomegaly on a Chest x-ray or other imaging

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- elevated level of cardiac biomarkers (Creatinine Kinase isoforms, Troponin I or T, Brain Natriuretic Peptide (BNP), N-Terminal pro b-type natriuretic peptide (NT-proBNP) above the normal reference range as defined by the local laboratory assays)
- initial evaluation of known/suspected heart failure based on diagnostic tests
- suspected inherited or acquired cardiomyopathy (e.g., restrictive, infiltrative, dilated, hypertrophic)
- suspected pulmonary hypertension. See **Pulmonary Hypertension CD-8.1.**
  - ECG changes of right ventricular hypertrophy
  - right ventricular hypertrophy or pulmonary artery dilation on other imaging
  - pulmonary embolism with persistent or new symptoms
- dilated aortic root and/or ascending aorta seen on other imaging
- suspected endocarditis with positive blood cultures indicating bacteremia
- suspected pericardial diseases
- cardiac mass suspected on other imaging
- to rule out intra-cardiac thrombus in individuals with left ventricular systolic dysfunction prior to undergoing catheter ablation of ventricular arrhythmia.
- ≥6 weeks post-myocardial infarction

Extra-cardiac conditions and therapies associated with cardiovascular disease or risk

- CONDITIONS
  - Initial cardiac evaluation of a known systemic, congenital, or acquired disease that could be associated with structural heart disease
  - At risk for developing iron-overload cardiomyopathy (hereditary hemochromatosis or hereditary or acquired hematologic conditions requiring multiple transfusions)
  - Known or suspected connective tissue disease or a genetic condition that predisposes to an aortic aneurysm or dissection (may repeat every 2 years if negative). See **Screening for Vascular related genetic connective tissue Disorders PVD-2.2**.
  - At risk for pulmonary hypertension. See **Pulmonary Hypertension CD-8.1.**
    - scleroderma
    - lupus
    - mixed connective tissue disease
    - Hereditary Hemorrhagic Telangiectasia
    - individuals with pulmonary hypertension mutations (e.g., BMPR2)
  - Suspected pulmonary hypertension in the presence of:
    - liver disease
    - lung disease

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

    - HIV
  - Newly diagnosed or strongly suspected cerebral ischemia or peripheral embolic event
- THERAPIES
  - Use of anorectic drugs, ergot derivatives, or other agents associated with valvular heart disease
  - Pre-procedure evaluation for TIPS (transjugular intrahepatic portosystemic shunt). See **Hepatic Arteries and Veins AB-43.1.**
  - Prior to solid organ transplant or hematopoietic stem cell transplant
  - Prior to exposure to cardiotoxic medications or radiation therapy. See **Cardiotoxic agent/Cancer Therapeutics-related Cardiac Dysfunction CD-12.1.**

Inherited cardiovascular conditions

- Individual has first-degree relative diagnosed with thoracic aortic aneurysm or dissection (may repeat every 2 years if negative). See **Screening for Vascular related genetic connective tissue Disorders PVD-2.2**, **Thoracic Aortic Aneurysm PVD-6.2.**
- Individual has first-degree relative diagnosed with bicuspid aortic valve. See **Screening for TAA in individuals with bicuspid aortic valves PVD-2.3.**
- Individual has diagnosed first-degree relative or member is genotype positive for an inherited cardiomyopathy including any of the following:
  - hypertrophic cardiomyopathy
  - non compaction cardiomyopathy
  - familial Dilated Cardiomyopathy
  - arrhythmogenic Cardiomyopathy (e.g., ARVC)

Additional indications

- One repeat echocardiogram is medically necessary if requested for agitated saline (bubble study) or contrast study (for evaluation of shunts or for left ventricular cavity opacification) when agitated saline or contrast were not administered at the time of the initial study and the results of the initial study indicate the need for agitated saline or contrast.
- Evaluation of congenital heart disease: see **Adult Congenital Heart Disease CD-11** and **Congenital Heart Disease PEDCD-2** in the Pediatric Cardiology imaging guidelines.

Frequency of Echocardiography Testing (CD-2.3)

CD.EC.0002.3.A
v2.0.2026

Repeat Testing by Interval

Repeat Transthoracic Echocardiography (TTE) is medically necessary for **any** of the following:

Every 3 years

Valvular heart disease (See also below indications for Valve surgery or intervention)

- bicuspid aortic valve
- mild aortic stenosis or aortic valve sclerosis without stenosis
- mild aortic or mitral regurgitation
- any mitral stenosis that is not severe, mitral valve area >1.5cm^2
- rheumatic valve changes with commissural fusion
- valve surgery including **any** of the following:
  - surgical valve repair
  - mechanical valve replacement
  - bioprosthetic valve replacement when <10 years since implant

Cardiomyopathy

- First-degree relative with a diagnosis of inherited cardiomyopathy including:
  - Hypertrophic Cardiomyopathy
  - Familial Dilated Cardiomyopathy
  - Idiopathic Dilated Cardiomyopathy
- Individuals genotype-positive for:
  - Familial Dilated Cardiomyopathy
  - Arrhythmogenic Cardiomyopathy (e.g., ARVC)

Every 2 years

Vascular disease

- First-degree relative with known thoracic aortic aneurysm or dissection a repeat echocardiogram is allowed every 2 years when both:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Prior aortic imaging (echo, CT, MR) is negative.
- Last aortic imaging was ≥2 years. See **Screening for Vascular related genetic connective tissue Disorders (PVD-2.2).**

Every year

Valvular heart disease (VHD)

(See also below indications for valve surgery or intervention)

- moderate or severe regurgitation
- moderate or severe stenosis
- significant valve deformity (regardless of extent of regurgitation or stenosis) when there is documentation of either:
  - thickened myxomatous valve
  - bileaflet prolapse
- surgical bioprosthetic valve replacement when ≥10 years since implant
- post-transcatheter valve repair or replacement

Cardiomyopathy/heart failure

- history of left ventricular systolic dysfunction to evaluate the effectiveness of ongoing therapy
- hypertrophic cardiomyopathy see **Hypertrophic Cardiomyopathy CD-14**
- frequent right ventricular pacing >40%
- chronic LBBB
- frequent PVCs defined as >10,000 PVCs within 24 hours or >10% PVC burden over 24 hours
- left ventricular non-compaction cardiomyopathy
- at risk for developing iron-overload cardiomyopathy (hereditary hemochromatosis or hereditary or acquired hematologic conditions requiring multiple transfusions)
- inherited neuromuscular, metabolic, hematologic or cutaneous syndromes that are known to be associated with the development of cardiomyopathy
- infiltrative cardiomyopathy

Pericardial disease

- Chronic pericardial effusions when findings would potentially alter therapy

Vascular disease

- Aortic root dilatation that has not yet been repaired. See **Thoracic aortic aneurysm PVD 6.2** and

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- For post-repair, see **Post-Aortic Endovascular/Open Surgery Surveillance Studies PVD-6.8**.

At risk for pulmonary hypertension

See **Pulmonary Hypertension CD-8.1**.

- Systemic Sclerosis or Scleroderma
- individuals with pulmonary hypertension mutations (e.g., BMPR2)
- first-degree relatives of individuals with pulmonary hypertension
- connective tissue disorder with symptoms consistent with pulmonary hypertension
- individuals with TR velocity ≥2.8m/s, with no other findings on additional testing
- individuals being treated with medications associated with pulmonary hypertension
- individuals who have a concern documented for pulmonary hypertension and had a negative echocardiogram but still show signs or symptoms of pulmonary hypertension

Every 6 months or twice a year

Valvular heart disease

- Asymptomatic, severe mitral regurgitation if valve surgery is being considered

Pulmonary Hypertension

- See below indications for Pulmonary Hypertension (See **Pulmonary Hypertension CD-8.1**).
- Surveillance of stable individuals with moderate or severe pulmonary hypertension (pulmonary artery systolic pressure ≥50mmHg)

Anytime

Repeat transthoracic echocardiogram is medically necessary **anytime** (without regard for the number or timing of previous echo studies) if there is a change in clinical status, or new signs and symptoms with documentation of **any** of the following:

- cardiac murmurs
- myocardial infarction or acute coronary syndrome
- congestive heart failure (new or worsening):
  - new symptoms of dyspnea
  - orthopnea
  - paroxysmal nocturnal dyspnea
  - elevated BNP
- known pericardial disease with clinical concern for cardiac tamponade or pericardial constriction
- infective endocarditis for any of the following:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - repeat imaging within 5-7 days for initially negative or inconclusive imaging when clinical suspicion of endocarditis remains high
  - new or worsening symptoms or signs of endocarditis
  - as needed to guide changes in antibiotic therapy
  - at completion of antibiotic therapy
- stroke/transient ischemic attack
- decompression illness
- prosthetic valve dysfunction or thrombosis
- cardiac transplant
- individuals with Left Ventricular Assist Device (LVAD)
- See also section on **Repeat testing per condition** below and **Left ventricular assist devices (LVAD) (CD-9.4)**.

Repeat Testing Per Condition

Repeat Transthoracic Echocardiography (TTE) is medically necessary for **any** of the following:

Valve surgery or intervention

Repeat Transthoracic Echocardiography (TTE) is medically necessary for any of the following:

Surgical valve repair or mechanical valve replacement
- 6 weeks post-surgery to establish baseline
- surveillance every 3 years after surgery

Surgical bioprosthetic valve replacement
- 6 weeks post-surgery to establish baseline
- surveillance every 3 years after surgery until 10 years
- then annually

TAVR follow-up
- 1 week after procedure to establish baseline
- 1 month post-procedure
- 1 year post-procedure
- then annually

Mitral Valve Repair (mitral valve clip) follow-up
- 1 month post-procedure
- 6 months post-procedure
- 1 year post-procedure

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- then annually

Transcatheter Tricuspid Valve Replacement follow-up

- TTE (CPT® 93306) is medically necessary post-procedure at the following intervals:
  - 1 month
  - 6 months
  - 1 year
  - then annually

See also **Transcatheter Aortic Valve Replacement (TAVR) (CD-4.8).**

See also **Percutaneous Mitral Valve Repair (mitral valve clip) (CD-13.5)**.

PFO closure, TIPS, Cardiac device therapy, LVAD

Repeat Transthoracic Echocardiography (TTE) is medically necessary for any of the following:

- **PFO Closure**
  - pre-operative evaluation for closure of PFO
  - post-procedural evaluation of PFO repair
  - 6 month follow-up after PFO repair
  - annually if there is a residual shunt on post-operative imaging

  For ASD closure, see **ASD-Atrial septal defects (CD 11.2.1)**.
- **TIPS (transjugular intrahepatic portosystemic shunt).** See **Hepatic Arteries and Veins (AB 43.1)**.
  - 1 time post-procedure for routine follow-up
  - **any time** post-procedure (either):
    - for new signs or symptoms
    - for concern for new or worsening pulmonary hypertension or heart failure
- **Cardiac device therapy**
  - Re-evaluation of EF is medically necessary 40 days after MI, 3 months after revascularization, or 3 months after maximally tolerated optimal medical therapy to determine either:
    - candidacy for device therapy
    - optimal choice of device
  - 1 time follow up within 12 months of implantation of a CRT-D device
- **Left ventricular assist device (LVAD).** See **Left ventricular assist devices (LVAD) (CD-9.4)**.
  - Prior to implant
  - Routine Post-implant at the following intervals:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- 2 weeks
- 1 month
- 3 months
- 6 months
- 12 months
- every 6 months thereafter

Pulmonary hypertension

Follow-up echocardiogram (TTE) on individuals with PH is medically necessary for any of the following:

- every 6 months for surveillance of stable individuals with moderate or severe pulmonary hypertension (pulmonary artery systolic pressure ≥50mmHg)
- 3 months after any change in PH therapy
- prior to planned intubation (e.g., for elective surgery)
- prior to planned pregnancy
- during pregnancy as often as requested by provider
- anytime, without regard for the number or timing of previous echo studies to evaluate change in clinical signs or symptoms

See also **Pulmonary Hypertension CD-8.1**.

Hypertrophic Cardiomyopathy (HCM)

Repeat Transthoracic Echocardiography (TTE) is medically necessary for individuals with hypertrophic cardiomyopathy for any of the following:

- **Surveillance imaging**
  - Every year
- **Mavacamten: Initiation of treatment**
  - Baseline at the beginning of treatment
  - 4 weeks after treatment initiation
  - 8 weeks after treatment initiation
  - 12 weeks after treatment initiation
  - Then every 12 weeks while on mavacamten
- **Mavacamten: Changes in treatment**
  - 4 weeks after any interruption of treatment (any missed dose)
  - After any dosage change (including restart of treatment):
    - 4 weeks after dosage change
    - 12 weeks after dosage change
  - After initiating a weak CYP2C19 inhibitor (e.g., omeprazole) or moderate CYP3A4 inhibitor (e.g., ciprofloxacin):

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

    - 4 weeks after start of medication
    - 12 weeks after start of medication
  - At any time regardless of timing of prior echo when there are new cardiac signs or symptoms, or worsening of clinical status
- **Post-Septal Reduction Therapy (SRT)**
  - Within 3 to 6 months after surgical myectomy or alcohol septal ablation

See also **Hypertrophic Cardiomyopathy CD-14**.

Cardiac Transplant

Anytime (without regard for the number or timing of previous ECHO studies) when there is a history of cardiac transplant, per transplant center protocol

Cardiotoxic Agents

For re-evaluation in an individual previously or currently undergoing therapy with cardiotoxic agents or radiation therapy, follow **Cardiotoxic agent/Cancer Therapeutics-Related Cardiac Dysfunction (CD-12.1)**.

Evidence Discussion

Transthoracic Echocardiogram

- Transthoracic echocardiogram (TTE) is an ultrasonic examination of the heart through the chest wall. Given that sound waves are used (sonography), there is no exposure to ionizing radiation or possible complications related to contrast induced nephropathy.
- It is readily accessible and transportable allowing for the test to be performed at multiple different locations with no need for blood work.
- TTE is widely accepted as initial imaging modality of choice for the general evaluation of cardiac and pericardial structure and function.
- Multiple evidence-based professional society guidelines indicate that TTE can be appropriately used for the evaluation of multiple cardiac issues including but not limited to evaluation of cardiac symptoms, dyspnea, and pulmonary hypertension.
- A complete comprehensive TTE will utilize multiple acoustic windows and incorporate 2D imaging with appropriate data; including measurements with color and spectral Doppler imaging.
- The test is performed and interpreted by qualified individuals in a facility that is accredited in performing echocardiograms.
- TTE is the primary imaging tool for screening of family members with thoracic aortic disease as well as genetic syndromes that are associated with thoracic aortic aneurysms and dissection. It is not medically necessary for screening of

Click Here to Return to the Main TOC

asymptomatic individuals in the general public in the absence of family history of cardiac, vascular, or associated connective tissue disorder.

- TTE offers real-time hemodynamic assessment which may be used in the guidance of therapeutic interventions.
- Repeat echocardiograms may be done for the surveillance of known valvular heart disease, cardiomyopathies, pulmonary hypertension, and cardiotoxic agents. The need for surveillance echocardiograms are dependent on factors such as morphology, severity, family history of cardiomyopathies, timing of surgery, left ventricular function, symptoms, and for follow-up of post cardiac structural interventions. Timing of surveillance echocardiograms are in alignment with recommendations from various national and international medical specialty organization guidelines and Appropriate Use Criteria based on studies which analyzed progression of valvular disease and timing of invasive intervention.
- Decisions regarding routine echocardiographic follow-up should not be based on the degree of regurgitation alone but should take into account associated structural valvular and cardiac abnormalities. For example, a structurally normal mitral valve with moderate mitral regurgitation by color flow Doppler and normal left atrial size, does not generally require routine echocardiographic follow-up. However, a thickened, myxomatous appearing mitral valve with bi-leaflet prolapse and only trivial or mild mitral regurgitation should be followed echocardiographically at routine intervals.

Transesophageal Echocardiography (TEE) (CD-2.4) (CD-2.5)

CD.EC.0002.5.A
v2.0.2026

Transesophageal Echocardiography (TEE)-Coding (CD-2.4)

TEE coding

Transesophageal Echocardiography	CPT®
TEE with 2-D, M-mode, probe placement, image acquisition, interpretation and report	93312
TEE probe placement only	93313
TEE image acquisition, interpretation, and report only	93314
TEE for congenital anomalies with 2-D, M-mode, probe placement, image acquisition, interpretation and report	93315
TEE for congenital anomalies, probe placement only	93316
TEE for congenital anomalies, image acquisition, interpretation and report only	93317

Doppler Echocardiography

Description	CPT®
Doppler echo, pulsed wave and/or spectral display	+93320
Doppler echo, pulsed wave and/or spectral display, follow-up or limited study	+93321
Doppler echo, color flow velocity mapping	+93325
Doppler echo, if performed, may be reported separately in addition to the primary TEE codes: CPT® 93312, CPT® 93314, CPT® 93315, and CPT® 93317	

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

C codes

HCPCS	Description	CPT®
C8925	TEE with 2-D, M-mode, probe placement, image acquisition, interpretation and report	93312
C8926	TEE for congenital anomalies with 2-D, M-mode, probe placement, image acquisition, interpretation and report	93315

- The complete transesophageal echocardiogram service, including both (1) probe (transducer) placement and (2) image acquisition/interpretation, is reported with CPT® 93312.
  - Probe placement only is reported with CPT® 93313.
  - The image acquisition/interpretation only is reported with CPT® 93314.
- Physicians assign codes CPT® 93312, CPT® 93313, and/or CPT® 93314 to report professional services if the test is performed in a hospital or other facility where the physician cannot bill globally.
  - Modifier-26 (professional component) is appended to the appropriate code.
  - CPT® 93313 and CPT® 93314 should never be used together. If both services are provided, CPT® 93312 is reported.
- Hospitals should report TEE procedures using CPT® 93312 (the complete service). CPT® 93313 and CPT® 93314 are not used for hospital billing.

Transesophageal Echocardiography (TEE)- Indications (CD-2.5)

TEE (CPT® 93312, 93320, and 93325) is medically necessary when there is documentation of **any** of the following:

- limited transthoracic echo window when further information is needed to guide management (e.g., suspected or confirmed endocarditis, suspected intracardiac mass, etc.)
- assessing valvular dysfunction, especially mitral regurgitation when TTE is inadequate and intervention is being considered to repair/replace valve
- evaluation of cardiac mass, suspected tumor, or thrombus
- pre-procedural assessment of PFO/ASD
- pre-operative evaluation prior to planned LVAD implant
- embolic source or intracardiac shunting when TTE is inconclusive
  - Examples: atrial septal defect, ventricular septal defect, patent foramen ovale, aortic cholesterol plaques, thrombus in cardiac chambers, valve vegetation, tumor
- embolic events when there is an abnormal TTE or a history of atrial fibrillation

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - clarify atria/atrial appendage, aorta, mitral/aortic valve beyond the information that other imaging studies have provided
- cardiac valve dysfunction
  - differentiation of tricuspid from bicuspid aortic valve in setting of aortic enlargement or significant stenosis or significant regurgitation
  - congenital abnormalities
- assessing for left atrial thrombus prior to cardioversion of atrial fibrillation or atrial flutter
- assessing for left atrial thrombus prior to planned atrial fibrillation ablation/pulmonary vein isolation procedure
- for initial imaging of ascending and descending thoracic aortic aneurysms
- For repeat imaging or established thoracic aneurysms, TEE is medically necessary **only** when imaging with CT or MR is contraindicated.
- TEE is medically necessary for the evaluation of individuals with hypertrophic cardiomyopathy if TTE is inconclusive for **any** of the following:
  - mitral regurgitation secondary to structural abnormalities of the mitral valve
  - subaortic membrane or aortic valve stenosis
- TEE is medically necessary for the pre-procedure planning for surgical myectomy or alcohol septal ablation evaluation of individuals with hypertrophic cardiomyopathy.
- Left atrial appendage (LAA) Closure device (e.g., WATCHMAN®) for any of the following:
  - pre-procedural evaluation
  - repeat imaging 45 days post-procedure
    - Another follow-up study is medically necessary before the 1-year surveillance when the imaging study at 45 days shows a peri-device gap ≥5 mm or Device Related Thrombus usually at 3-6 months.
  - 1 year post-procedure

Evidence Discussion

- Transesophageal echocardiogram (TEE) is a semi-invasive ultrasonic examination of the heart through the esophagus. Due to the proximity of the esophagus to the heart and great vessels, it allows for additional and more accurate information than transthoracic echocardiography for several specific diagnoses, catheter-based cardiac interventions, and cardiac surgery.
- TEE is utilized not only for diagnostic purposes but also for dynamic decision-making with cardioversion, surgical intervention, and assessment of surgical repair.
- TEE has become an essential imaging tool for pediatric and adult cardiologists, cardiac surgeons, and anesthesiologists and is used in outpatient and inpatient settings as well as operating rooms.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- The test is performed and interpreted by physicians that have demonstrated both cognitive and technical competence in TEE.
- TEE is readily accessible, has no ionizing radiation exposure, and does not require use of IV contrast.
- There are relative and absolute contraindications which are reviewed prior to insertion of the TEE probe which include and are not limited to esophageal pathology, coagulopathy, and cervical spine injury.

Stress Echocardiography (Stress Echo) (CD-2.7)

CD.EC.0002.7.A
v2.0.2026

Stress Echo – Coding

Associated codes

Stress Echocardiography	CPT®
Echo, transthoracic, with (2D), includes M-mode, during rest and exercise stress test and/or pharmacologically induced stress, with report;	93350
Echo, transthoracic, with (2D), includes M-mode, during rest and exercise stress test and/or pharmacologically induced stress, with report: including performance of continuous electrocardiographic monitoring, with physician supervision	93351
Doppler Echocardiography	
Doppler echo, pulsed wave and/or spectral display	+93320
Doppler echo, pulsed wave and/or spectral display, follow-up/limited study	+93321
Doppler echo, color flow velocity mapping	+93325

Associated HCPCS codes

CPT®	Stress Echocardiography	HCPCS
93350	Echo, transthoracic, with (2D), includes M-mode, during rest and exercise stress test and/or pharmacologically induced stress, with report;	C8928
93351	Echo, transthoracic, with (2D), includes M-mode, during rest and exercise stress test and/or pharmacologically induced stress, with report: including performance of continuous electrocardiographic monitoring, with physician supervision	C8930

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

CPT® 93350 and CPT® 93351 do not include Doppler studies.

Doppler echo (CPT® +93320 and CPT® +93325), if performed, may be reported separately in addition to the primary SE codes: CPT® 93350 or CPT® 93351.

Stress Echocardiogram-Indications Other Than Ruling-out CAD (CD-2.7)

CPT® 93350 or 93351

- See: **Stress Testing with Imaging – Indications (CD-1.4)**
- In addition to the evaluation of CAD, stress echo can be used to evaluate the following conditions:
  - dyspnea on exertion (specifically to evaluate pulmonary hypertension)
  - right heart dysfunction
  - valvular heart disease when the outcome would affect a therapeutic or interventional decision
  - pulmonary hypertension when the outcome will measure response to therapy and/or prognostic information
  - hypertrophic cardiomyopathy (as defined in **Obstructive Hypertrophic Cardiomyopathy (HCM) (CD-12.3)** for **either** of the following:
    - Exercise stress echo (CPT® 93351 or 93350) is medically necessary for the detection and quantification of dynamic left ventricular outflow tract obstruction in symptomatic individuals with HCM who do **not** have a resting or provocable outflow tract gradient ≥50 mm Hg on TTE.
    - Stress echo can be repeated when there is documentation of **any** of the following:
      - in 1 to 2 years if the resting or provocable outflow tract gradient is <30 mm Hg on prior stress echo
      - worsening symptoms
      - There has been a therapeutic change (i.e., change in medication, surgical procedure performed).
- In general, spectral Doppler (CPT® 93320 or 93321) and color-flow Doppler (CPT® 93325) are medically necessary in the evaluation of the above conditions and can be added to the stress echo code.

Evidence Discussion

- Stress echocardiography is a ultrasonic examination of the heart through the chest wall during rest and stress. Given the ultrasound modality, there is no exposure to ionizing radiation or concern for contrast induced renal failure.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Stress echocardiography is used to assess for global and regional systolic function and evaluation of valvular function at rest and during stress. This allows for non-invasive diagnosis and management of coronary artery disease, various cardiomyopathies, pulmonary hypertension, and valvular heart disease.
- A complete comprehensive stress echocardiogram will incorporate 2D imaging with multiple acquisition windows during rest and stress and may also incorporate color and spectral Doppler imaging. This provides a dynamic evaluation of myocardial and valvular structure and function under physiological (exercise) or pharmacological stress.
- The test is performed and interpreted by qualified individuals in a facility that is proficient in echocardiograms in compliance with published criteria for quality cardiac diagnostic testing.

3D Echocardiography (CD-2.9)

CD.EC.0002.9.A
v2.0.2026

3D Echocardiography – Coding

Description	CPT®
3D rendering with interpretation and reporting of computed tomography, magnetic resonance imaging, ultrasound, or other tomographic modality with image post-processing under concurrent supervision; not requiring image post-processing on an independent workstation	76376
3D rendering with interpretation and reporting of computed tomography, magnetic resonance imaging, ultrasound, or other tomographic modality with image post-processing under concurrent supervision; requiring image post-processing on an independent workstation	76377
3D echocardiographic imaging and post-processing during transesophageal echocardiography, or during transthoracic echocardiography for congenital cardiac anomalies, for the assessment of cardiac structure(s) (e.g., cardiac chambers and valves, left atrial appendage, interatrial septum, interventricular septum) and function, when performed (List separately in addition to code for echocardiographic imaging) Code with (93303-93304, 93312, 93314, 93315, 93317, 93350-93351)	+93319

3D Echocardiography – Indications (CD-2.9)

Echocardiography with 3-dimensional (3D) rendering is becoming universally available, yet its utility remains limited based on the current literature.

- CPT ® 93319 with one of the following (CPT® 93303, 93304, 93312, 93314, 93315, or 93317) for congenital cardiac abnormalities
- 3D Echo (CPT® 76376 or CPT® 76377) may be medically necessary when a primary echocardiogram is approved and **one** of the following is needed:
  - left ventricular volume and ejection fraction assessment when measurements are needed for treatment decision (e.g., implantation of ICD, alteration in cardiotoxic chemotherapy, cardiac transplant)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- mitral valve anatomy specifically related to mitral valve stenosis
- pre-procedural evaluation of left atrial appendage occlusion (e.g., WATCHMAN®)
- pre-operative evaluation for LVAD implant
- guidance of transcatheter procedures such as:
  - mitral valve clipping
  - TAVR
  - left atrial appendage closure device (e.g., WATCHMAN®)

Evidence Discussion

- 3D echocardiography (3DE) is a newer modality of ultrasonic examination of the heart through the chest wall or through the esophagus that is added on to either a transthoracic or transesophageal echocardiogram.
- This allows for both real-time and post-processed 3D analysis of the cardiac structures and function. This produces images that are less constrained than that of 2D echocardiograms.
- 3DE is readily accessible and transportable allowing for the test to be done at multiple different locations with no need for blood work or IV line insertion.
- 3DE has become important in pre-surgical planning, guidance of catheter intervention, and functional assessment of the heart in various cardiac conditions including but not limited to congenital heart disease, valvular disease, and structural heart disease.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Myocardial Strain Imaging (CD-2.12)

CD.EC.0002.12.A
v2.0.2026

CPT® 93356

- Myocardial strain imaging (CPT® 93356, speckle tracking longitudinal strain) is medically necessary for the initial evaluation of LVH, in addition to the primary echocardiogram, when there is documentation of **both**:
  - unclear etiology of LVH not due to hypertensive heart disease
  - concern for infiltrative cardiomyopathy
- Myocardial strain imaging is medically necessary in heart transplant evaluation and surveillance per transplant protocol.
- Myocardial strain imaging (CPT® 93356) in addition to the primary echocardiogram in individuals receiving therapy with cardiotoxic agents for **any** of the following:
  - Initial evaluation-prior to treatment with **either**:
    - medications that could result in cardiotoxicity/heart failure
    - radiation that could result in cardiotoxicity/heart failure
  - re-evaluation of an individual previously or currently undergoing therapy as per echocardiogram parameters (see **Cardiotoxic agent/Cancer Therapeutics-Related Cardiac Dysfunction (CD-12.1))**
  - re-evaluation of an individual undergoing therapy with worsening symptoms

Evidence Discussion

- Myocardial strain imaging or speckle-tracking echocardiography (STE) is a modern ultrasound technique that is an adjunct to traditional transthoracic echocardiography to evaluate myocardial deformation.
- Given the ultrasound modality, there is no exposure to ionizing radiation or concern for contrast-induced renal failure.
- The main areas of application of this technique have been in the assessment of myocardial mechanics, ischemic heart disease, cardiomyopathies, LV diastolic dysfunction, and in detecting sub-clinical myocardial dysfunction in individuals undergoing chemotherapy for cancer or in those affected by heart valve diseases.
- STE is considered the optimal deformation parameter for the detection of subclinical LV dysfunction which allows for clinical intervention prior to reduction in LVEF particularly useful in the field of cardio-oncology.

Myocardial Perfusion Imaging (MPI) (CD-3.2)

CD.NC.0003.1.A
v2.0.2026

MPI – Coding

Nuclear Cardiac Imaging Procedure Codes

Myocardial Perfusion Imaging (MPI)	CPT®
MPI, tomographic (SPECT) (including attenuation correction, qualitative or quantitative wall motion, ejection fraction by first pass or gated technique, additional quantification, when performed); single study, at rest or stress (exercise or pharmacologic)	78451
MPI, tomographic (SPECT) (including attenuation correction, qualitative or quantitative wall motion, ejection fraction by first pass or gated technique, additional quantification, when performed); multiple studies, at rest and/or stress (exercise or pharmacologic) and/or redistribution and/or rest reinjection	78452
Myocardial perfusion imaging, planar (including qualitative or quantitative wall motion, ejection fraction by first pass or gated technique, additional quantification, when performed); single study, at rest or stress (exercise or pharmacologic)	78453
Myocardial perfusion imaging, planar (including qualitative or quantitative wall motion, ejection fraction by first pass or gated technique, additional quantification, when performed); multiple studies, at rest and/or stress (exercise or pharmacologic) and/or redistribution and/or rest reinjection	78454
Absolute quantitation of myocardial blood flow (AQMBF), single-photon emission computed tomography (SPECT), with exercise or pharmacologic stress, and at rest, when performed (List separately in addition to code for primary procedure)	+0742T

- The most commonly performed myocardial perfusion imaging are single (at rest or stress, CPT® 78451) and multiple (at rest and stress, CPT® 78452) SPECT studies.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Less commonly ordered are planar studies (CPT 78453 and 78454) see **Stress Testing with Imaging – Indications (CD-1.4)**.

- Evaluation of the individual's left ventricular wall motion and ejection fraction are routinely performed during MPI and are included in the code's definition.
- First pass studies, (CPT® 78481 and CPT® 78483), MUGA, (CPT® 78472 and CPT® 78473) and SPECT MUGA (CPT® 78494) should not be reported in conjunction with MPI codes.
- Attenuation correction, when performed, is included in the MPI service by code definition. No additional code should be assigned for the billing of attenuation correction.

- **Multi-day Studies:** In the absence of written payer guidelines to the contrary, it is not appropriate to bill separately for the rest and stress segments of MPI even if performed on separate calendar dates. A single code is assigned to define the entire procedure on the date all portions of the study are completed.

Note:

3D rendering should not be billed in conjunction with MPI.

MPI – Indications (CD-3.2)

See: **Stress Testing with Imaging – Indications (CD-1.4)**

Absolute quantitation of myocardial blood flow (AQMBF)(SPECT)

AQMBF obtained by CZT-SPECT is considered experimental, investigational, or unproven at this time.

Evidence Discussion

Appropriate Use Criteria from major professional societies including the American College of Cardiology and the American Heart Association support the use of myocardial perfusion imaging (MPI) with single photon emission computed tomography (SPECT) for individuals with signs or symptoms consistent with coronary artery disease (CAD) such as typical angina. In addition, they support the use of SPECT perfusion imaging in symptomatic individuals with known CAD and those with prior interventions such as coronary artery bypass surgery, coronary stenting, and preoperative risk stratification. These guidelines balance the appropriate testing of individuals with SPECT versus medically unnecessary and potentially harmful testing and downstream procedures.

Also, as supported by society guidelines, use of SPECT is medically necessary in detection of cardiac transthyretin amyloidosis (ATTR) after light chain amyloidosis (AL) is ruled out by appropriate blood and urine testing.

Multi-gated Acquisition (MUGA) Coding (CD-3.3)

CD.NC.0003.3.A
v2.0.2026

Cardiac blood pool imaging, or radionuclide ventriculography, can be used to evaluate ventricular function. Cardiac blood pool imaging includes first pass studies (CPT® 78481 and 78483) as well as gated equilibrium studies (CPT® 78472, 78473, 78494, and +78496).

Gated equilibrium studies can also be referred to as multi-gated acquisition (MUGA) scan or equilibrium radionuclide angiography (ERNA). Imaging for gated equilibrium studies can be planar or 3D (single photon emission computed tomography, SPECT).

Of note, all cardiac blood pool imaging is synchronized with electrocardiographic RR interval (EKG-gated); thus, regular rhythm is required for accurate LV assessment.

Gated Equilibrium Studies – Planar	CPT®
Cardiac blood pool imaging, gated equilibrium; planar, single study at rest or stress, wall motion study plus ejection fraction, with or without quantitative processing	78472
Cardiac blood pool imaging, gated equilibrium; planar, multiple studies, wall motion study plus ejection fraction, at rest and stress, with or without additional quantification	78473
Gated Equilibrium Studies-SPECT	
Cardiac blood pool imaging, gated equilibrium, SPECT, at rest, wall motion study plus ejection fraction, with or without quantitative processing	78494
First Pass studies	
Cardiac blood pool imaging (planar), first pass technique; single study, at rest or with stress (exercise and/or pharmacologic), wall motion study plus ejection fraction, with or without quantification	78481

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Gated Equilibrium Studies – Planar	CPT®
Cardiac blood pool imaging (planar), first pass technique; multiple studies, at rest and with stress (exercise and/or pharmacologic), wall motion study plus ejection fraction, with or without quantification	78483
Cardiac blood pool imaging, gated equilibrium, single study, at rest, with right ventricular ejection fraction by first pass technique (List separately in addition to code for primary procedure) This CPT code is an add-on code to 78472.	+78496

- The technique employed for a MUGA service guides the code assignment.
  - CPT® 78472 is used for a planar MUGA scan at rest or stress.
  - CPT® 78473 for planar MUGA scans, multiple studies at rest and stress.
- Planar MUGA studies (CPT® 78472 and CPT® 78473) should not be reported in conjunction with:
  - SPECT MPI (CPT® 78451-CPT® 78454)
  - First pass studies (CPT® 78481-CPT® 78483)
  - SPECT MUGA (CPT® 78494).
- CPT® +78496 is assigned only in conjunction with CPT® 78472.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

MUGA Study – Cardiac Indications (CD-3.4)

CD.NC.0003.4.A
v2.0.2026

MUGA (Multi Gated Acquisition) – Blood Pool Imaging Indications

- Echocardiography is the preferred method of following left ventricular systolic function.
- MUGA may be medically necessary when a recent ECHO, as indicated in **Transthoracic Echocardiography (TTE) – Indications (CD-2.2)** and/or **Frequency of Echocardiography Testing (CD 2.3)**, was technically limited and prevented accurate assessment of left ventricular function.
- MUGA is medically necessary when there is a significant discrepancy between LVEF assessment by ECHO and another modality (i.e., one study reports normal LVEF and the other, a reduced LVEF) AND there is clear documentation as to how quantitative measurement of LVEF will affect individual management (e.g., implantation of an ICD, alteration in cardiotoxic chemotherapy, etc.).
- MUGA may be performed in place of an ECHO in the following circumstances:
  - to determine candidacy for ICD/CRT and/or to determine optimal choice of device in individuals who meet criteria for ICD based on ejection fraction and other criteria
  - when previously or currently undergoing therapy with potentially cardiotoxic agents, including chemotherapy and radiation, AND a history of previous low LV ejection fraction (LVEF <50%). See **Cardiotoxic agent/Cancer Therapeutics-Related Cardiac Dysfunction (CD-12.1)**.
- MUGA is not medically necessary when requested simply to compare LVEF by the same modality. A prior MUGA is not a reason to approve another MUGA.

Right ventricular first pass study

- (CPT® 78472 and 78496) may be performed when ECHO is technically limited and prevents accurate assessment of RV function AND when further information about RV function is needed to guide management (e.g., established/diagnosed pulmonary hypertension, suspected or confirmed pulmonary embolus).

First pass studies

- First pass studies (CPT® 78481 and CPT® 78483) may be approved in place of MUGA when indications are met for MUGA and/or there is need for information that cannot be obtained by MUGA.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- First pass studies, (CPT® 78481 and CPT® 78483), MUGA (CPT® 78472 and CPT® 78473), and SPECT MUGA (CPT® 78494) should not be reported in conjunction with MPI codes.

Evidence Discussion

Multi-gated acquisition (MUGA) imaging (also referred to as radionuclide angiography, gated blood pool scan, equilibrium radionuclide angiography) is a method to measure ejection fraction and wall motion of the heart.

Appropriate Use Criteria from major professional societies including the American College of Cardiology and the American Heart Association support the use of planar imaging and/or single photon emission computed tomography (SPECT) of labeled red blood cells for individuals who require accurate assessment of ejection fraction and/or wall motion when echocardiography or other imaging approaches are inadequate or disparate. This includes individuals with cardiomyopathy and those exposed to cardio-toxic agents.

Myocardial Sympathetic Innervation Imaging in Heart Failure (CD-3.6)

CD.NC.0003.6.A
v2.0.2026

- Nuclear imaging using I-123-meta-iodobenzylguanidine (I-123-mIBG) in an attempt to image increased myocardial sympathetic activity is considered to be experimental and investigational.
- The AMA has established the following set of Category III codes to report these studies:
  - CPT® 0331T Myocardial sympathetic innervation imaging, planar qualitative and quantitative assessment
  - CPT® 0332T Myocardial sympathetic innervation imaging, planar qualitative and quantitative assessment; with tomographic SPECT

Background and Supporting Information

In heart failure, the sympathetic nervous system is activated in order to compensate for the decreased myocardial function. Initially, this is beneficial. However, long-term this compensatory mechanism is detrimental and causes further damage.

Markers have been developed using radioactive iodine in an attempt to image this increased myocardial sympathetic activity. Currently, AdreView™ (Iodine-123 meta-iodobenzylguanidine) is the only FDA-approved imaging agent available for this purpose.

Evidence Discussion

I-123-meta-iodobenzylguanidine (MIBG) imaging of the sympathetic nerve activity of the heart has been proposed and approved for the identification of individuals with heart failure. However, its clinical utility has not found widespread acceptance, and its clinical usefulness remains in question. There are no societal guidelines for its routine use. The guidelines contain many other imaging platforms such as echocardiography, magnetic resonance imaging, perfusion, and metabolic imaging that have proven superior for the diagnosis and management of individuals with heart failure.

Click Here to Return to the Main TOC

Non-imaging Heart Function and Cardiac Shunt Imaging (CD-3.7)

CD.NC.0001.7.A
v2.0.2026

- Procedures reported with CPT® 78414 and CPT® 78428 are essentially obsolete but are medically necessary when other preferred modalities are unavailable or non-diagnostic.
- Echocardiogram is the preferred method for cardiac shunt detection, rather than the cardiac shunt imaging study described by CPT® 78428.
- Ejection fraction can be obtained by echocardiogram, SPECT MPI, MUGA study, cardiac MRI, cardiac CT, or cardiac PET depending on the clinical situation, rather than by the non-imaging heart function study described by CPT® 78414.

Evidence Discussion

Non-imaging Heart Function and Cardiac Shunt Imaging radionuclide techniques are no longer in use in current clinical practice. These techniques have been rendered obsolete and have been replaced by other cardiac imaging modalities that provide far superior structural and functional information to guide clinical management decisions. The preferred cardiac imaging modalities in current clinical use that have replaced the obsolete techniques include echocardiography, SPECT MPI, MUGA study, cardiac MRI, cardiac CT, and cardiac PET.

Cardiac CT and CTA-General information and Coding (CD-4.1)

CD.CT.0004.1.A
v2.0.2026

Associated Codes

Cardiac Imaging Procedure Codes

Cardiac CT and CCTA	CPT®
CT, heart, without contrast, with quantitative evaluation of coronary calcium • The code set for Cardiac CT and CCTA (CPT® 75572-CPT® 75574), include quantitative and functional assessment (for example, calcium scoring) if performed • CPT® 75571 describes a non-contrast CT of the heart with calcium scoring and should be reported only when calcium scoring is performed as a stand-alone procedure. ◦ Can be used to report a preliminary non-contrast scan which indicates an excessive amount of calcium such that the original scheduled study must be discontinued. ◦ CPT® 75571 should not be reported in conjunction with any of the contrast CT/CTA codes (CPT® 75572-CPT® 75574).	75571
CT, heart, with contrast, for evaluation of cardiac structure and morphology (including 3D image post-processing, assessment of cardiac function, and evaluation of venous structures, if performed).	75572
Computed tomography, heart, with contrast material, for evaluation of cardiac structure and morphology in the setting of congenital heart disease (including 3D image post-processing, assessment of left ventricular [LV] cardiac function, right ventricular [RV] structure and function and evaluation of vascular structures, if performed).	75573
CTA, heart, coronary arteries and bypass grafts (when present), with contrast, including 3D image post-processing (including 3D image post-processing, assessment of cardiac function, and evaluation of venous structures, if performed).	75574

Cardiac CT and CCTA	CPT®
Quantification and characterization of coronary atherosclerotic plaque to assess severity of coronary disease, derived from augmentative software analysis of the data set from a coronary computed tomographic angiography, with interpretation and report by a physician or other qualified health care professional	75577
Non-invasive estimate of coronary fractional flow reserve (FFR) derived from augmentative software analysis of the data set from a coronary computed tomography angiography, with interpretation and report by a physician or other qualified health care professional	75580

Cardiac CT and CTA-General information

- Only 1 code from the set: CPT® 75572-CPT® 75574 can be reported per encounter.
- CPT® 75574 includes evaluation of cardiac structure and morphology when performed; therefore, additional cardiac CT code/s should not be assigned.

Background and Supporting Information

The high negative predictive value (98%-99%) of CCTA in ruling out significant coronary artery disease has been confirmed in multiple studies.

3D rendering should not be billed in conjunction with Cardiac CT and CCTA.

CT for Coronary Calcium Scoring (CD-4.2)

CD.CT.0004.2.A
v2.0.2026

CPT® 75571

Coronary artery calcium score is **not** supported for evaluation of CAD in symptomatic individuals.

CT Calcium Scoring-Asymptomatic and for CAD Screening

- Coronary artery calcium score is medically necessary when there is documentation of **all** of the following:
  - Results will impact risk-based decisions for preventive interventions.
  - an LDL-C level ≥70 mg/dL (1.8mmol/L) AND <190mg/dL (4.9mmol/L)
  - Individual is an adult age 40-75.
  - 10-year ASCVD risk including pooled cohort equation is between 5.0% to 19.9%
  - There is no documented CAD.
  - Individual is not currently on a statin.
  - Individual is not a smoker.
  - There is no history of diabetes.
  - There is no family history of premature CAD (occurring before age 56 in males or before age 66 in females).
  - There has been no calcium score performed in the previous 5 years.
  - There has been no prior calcium score >0.
- Coronary calcium scoring is not medically necessary in someone with known CAD.

Suspected or Known Low Gradient Aortic Stenosis

- Coronary artery calcium score is medically necessary in low gradient aortic stenosis when symptomatic, severe aortic stenosis is suspected. Low gradient aortic stenosis is defined as an AVA <1 and a mean gradient <40mmHg.

Individuals with a history of chest radiation therapy

CT calcium scoring is considered medically necessary to evaluate for radiation induced CAD when all of the following conditions exist:

- The individual has no symptoms suspicious for ischemia such as chest discomfort located retrosternally, epigastric, or referred pain (pain that is felt in a place different

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

than the source) in the neck, shoulder, arm, or jaw described as pain, pressure, constricting, or tightness occurring with exertion or emotional stress and relieved by rest, nitroglycerin, or both.
- The individual has no clinical history or prior cardiac imaging documenting CAD.
- There has been no prior calcium score >0.
- There has been ≥5 years since the last RT (radiotherapy/radiation) treatment for the initial study or at least 5 years since the last CT calcium scoring for subsequent testing.

Evidence Discussion

The identification of coronary artery calcium (CAC) on a non-contrast computed tomography signifies the presence of coronary atherosclerosis and predicts major cardiac events independent of clinical risk factors. Measuring CAC score has been widely adopted to assist in the risk reclassification of coronary heart disease and to serve as an arbitrator for statin and aspirin therapy initiation. Whilst this general screening strategy brings precision to risk assessment, the most cost-effective implementation algorithm has not been studied systematically. This is reflected in the variation of major global and inter-societal guidelines for CAC scoring with unknown public health and economic ramification. Based on moderate quality, non-randomized evidence, the American College of Cardiology and the American Heart Association have specified the following clinical scenarios where CAC scoring is most likely to impact risk-based decision for preventive interventions:

- an LDL-C level ≥70mg/dL (1.8mmol/L) AND <190mg/dL (4.9mmol/L)
- Individual is an adult age 40-75.
- 10-year Atherosclerotic Cardiovascular Disease (ASCVD) risk including pooled cohort equation is between 5.0% to 19.9%.
- There is no documented coronary artery disease (CAD).
- Individual is not currently on a statin.
- Individual is not a smoker.
- There is no history of diabetes.
- There is no family history of premature CAD.
- There has been no calcium score performed in the previous 5 years.
- There has been no prior calcium score >0.

In addition to CAC, the degree of calcification of the aortic valve has been demonstrated to correlate with the degree of aortic stenosis and prognosis. The utility of calcium scoring has been extended to the aortic valve in the setting of symptomatic, low gradient aortic stenosis (defined as an aortic valve area of less than 1cm^2 and mean gradient of less than 40mmHg), when severe aortic stenosis is suspected.

CCTA – Indications for CCTA (CD-4.3)

CD.CT.0004.3.A
v2.0.2026

CCTA (CPT® 75574)

CCTA is medically necessary for any of the following:

- new, recurrent, or worsening cardiac chest pain as defined in **General Guidelines (CD-1.0)**
- new, recurrent, or worsening symptoms of chest pain, or unexplained exertional dyspnea, or unexplained exertional fatigue, and any of the following:
  - Symptoms persist after a normal stress test.
  - equivocal, borderline, abnormal or discordant prior noninvasive evaluation since the onset of symptoms where obstructive coronary artery disease remains a concern
  - new abnormal rest ECG findings since the onset of symptoms, such as a new LBBB or T-wave inversions (not including isolated T wave inversion in III or leads v1-2), when ischemia is a concern
  - a history of prior CABG when the **only** concern is for graft patency
  - Individual has undergone an urgent evaluation (ER or urgent care) of the symptoms since the onset.
  - history of cardiac transplant (e.g., concern for transplant vasculopathy)
  - history of chest radiation therapy
  - Chest pain occurring with syncope
  - Coronary artery calcium score (CAC) score ≥100
  - Individuals 50 years of age or above with 2 or more of the following CV risk factors:
    - diabetes
    - current cigarette smoking
    - family history of premature CAD
    - hypertension
    - hyperlipidemia
    - history of adverse pregnancy outcomes (APOs)
  - Prior history of PCI (percutaneous coronary intervention) or CABG (coronary artery bypass graft surgery) or a history of obstructive CAD as defined in **General Guidelines (CD-1.0)** and **any** of the following:
    - Cardiac chest pain as defined in **General Guidelines (CD-1.0)**
    - Anginal equivalents such as atypical chest pain, exertional dyspnea or exertional fatigue
    - Symptoms similar to prior ischemic episode

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Evaluation of an individual under the age of 40 for suspected anomalous coronary artery(ies) or for treatment planning when there is a history of one or more of the following:
  - syncopal episodes during strenuous activities
  - persistent chest pain brought on by exertion or emotional stress and normal stress test
  - full sibling(s) with history of sudden death syndrome before age 40 or with documented anomalous coronary artery
  - resuscitated sudden death and contraindications for conventional coronary angiography
  - prior nondiagnostic coronary angiography in determining the course of the anomalous coronary artery in relation to the great vessels, origin of a coronary artery or bypass graft location (any):
    - Anomalies of origin:
      - LCA or the RCA arising from the pulmonary artery
      - interarterial course between the pulmonary artery and the aorta of either the RCA arising from the left sinus of Valsalva or the LCA arising from the right sinus of Valsalva
    - Anomalies of course:
      - myocardial bridging
    - Anomalies of termination:
      - coronary artery fistula
- Initial imaging study in individuals with hypertrophic cardiomyopathy and stable anginal symptoms
  - Chest discomfort is common in individuals with hypertrophic cardiomyopathy. The incidence of false positive myocardial perfusion imaging abnormalities is higher in these individuals, whereas the incidence of severe coronary artery stenosis is low.
- Individuals who have recovered from unexplained sudden cardiac arrest in lieu of invasive coronary angiography **(both)**:
  - confirm the presence or absence of ischemic heart disease
  - exclude the presence of an anomalous coronary artery

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

CCTA – Regardless of Symptoms (CD-4.4)

CD.CT.0004.4.A
v2.0.2026

CPT® 75574

- Evaluation of newly diagnosed congestive heart failure or cardiomyopathy (all):
  - No prior history of coronary artery disease, the ejection fraction is <50%
  - No contraindications to cardiac CT angiography
  - No cardiac catheterization, SPECT, cardiac PET, or stress echocardiogram has been performed since the diagnosis of congestive heart failure or cardiomyopathy.
- Unclear coronary artery anatomy despite conventional cardiac catheterization
- Evaluation of structural heart disease or CAD for use of class IC antiarrhythmic agent (flecainide or propafenone) in place of stress test with imaging
- Ventricular tachycardia (3-beat runs or greater), exercise induced ventricular tachycardia or ventricular fibrillation
- Re-do CABG **(either)**:
  - assess bypass graft patency
  - evaluate the location of the left internal mammary artery (LIMA) and or right internal mammary artery (RIMA) prior to repeat bypass surgery
- Follow-up Left main stent 1 time at 6-12 months
- Pre-procedural planning for Percutaneous Coronary Intervention (PCI) of Chronic Total Occlusion (CTO)
- Evaluate coronary artery anomalies and other complex congenital heart disease of cardiac chambers or great vessels:
  - To evaluate the great vessels, CTA Chest (CPT® 71275) can be performed instead of CCTA or in addition to CCTA.
  - For anomalous pulmonary venous return, can add CT Abdomen and Pelvis with contrast (CPT® 74177).
  - See **Adult Congenital Heart Disease CD-11** for lesion specific imaging.
- When CCTA will replace conventional invasive coronary angiography for any of the following:
  - Delayed presentation or retrospective evaluation of suspected Takotsubo syndrome (stress cardiomyopathy)
  - Preoperative assessment of the coronary arteries in planned surgery for any of the following:
    - Aortic dissection

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

        - Aortic aneurysm
        - Valvular surgery
        - Liver transplant (for initial pre-transplant evaluation and may be repeated once in 3 years)
    - To assess for coronary involvement in individuals with systemic vasculitis (e.g. Giant Cell Arteritis, Takayasu's, Kawasaki's disease) when there are clinical features suggestive of underlying vasculitis including:
        - unexplained elevated cardiac markers (erythrocyte sedimentation rate, C-reactive protein)
        - constitutional symptoms (fever, chills, night sweats, weight loss)
        - multiple visceral infarcts in the absence of embolic etiology
- For **Cardiac Trauma**, see also **Cardiac Trauma – Imaging (CD-10.1)**.
- Preoperative assessment for either:
    - planned liver or kidney transplant
    - in place of stress testing with imaging for high-risk or intermediate-risk surgery as follows:
        - **High-risk Surgery:** All individuals in this category should receive an imaging stress test if there has not been an imaging stress test within 1 year unless the individual has developed new cardiac symptoms or a new change in the EKG since the last stress test.
        - **Intermediate-risk Surgery:** One or more clinical risk factors and unable to perform an ETT per guidelines if there has not been an imaging stress test within 1 year unless the individual has developed new cardiac symptoms or a new change in the EKG since the last stress test.
        - Clinical Risk Factors (for cardiac death and non-fatal MI at time of non-cardiac surgery)
            - History of ischemic heart disease (previous MI, previous positive stress test, use of nitroglycerin, typical angina, ECG Q waves, previous PCI or CABG)
            - History of compensated previous congestive heart failure (history of heart failure, previous pulmonary edema, third heart sound, bilateral fine crackles, chest x-ray showing heart failure)
            - History of previous TIA or stroke
            - Diabetes Mellitus
            - Creatinine level >2mg/dL

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

High-risk (> 5%)	Intermediate-risk (1-5%)	Low-risk (<1%)
• Open aortic and other major open vascular surgery • Open peripheral vascular surgery • Esophagectomy • Pneumonectomy • Open intraperitoneal and/or intrathoracic surgery with organ resection	• Open intraperitoneal and/or intrathoracic surgery without major organ resection • Open carotid endarterectomy • Head and neck surgery • Open orthopedic surgery • Open prostate surgery	• Endoscopic procedures • Superficial procedures • Cataract surgery • Breast surgery • Ambulatory surgery • Laparoscopic and endovascular procedures that are unlikely to require further extensive surgical intervention

Anatomical and Functional Analysis of CCTA Results (CD-4.5)

CD.CT.0004.5.A
v2.0.2026

Fractional flow reserve by computed tomography

CPT® 75580

Fractional flow reserve (FFR) is typically measured using invasive techniques. FFR can be obtained non-invasively from coronary computed tomography angiography data (FFR-CT).

- Indications:
  - FFR-CT is medically necessary to further assess CAD seen on a recent CCTA that is of uncertain physiologic significance

Coronary CTA plaque quantification

CPT® 75577

Coronary CT plaque quantification or coronary plaque analysis using data from CCTA is medically necessary when **all** of the following conditions exist:

- The individual has acute or stable chest pain with no known coronary artery disease (CAD).
- Results from the current completed and interpreted CCTA indicate any of the following risk categories:
  - intermediate risk
  - CAD-RADS 1
  - CAD-RADS 2
  - CAD-RADS 3
- Cardiac evaluation is negative or inconclusive for acute coronary syndrome.

Non-indications

- Coronary CTA plaque quantification or coronary plaque analysis using data from CCTA is not medically necessary in any of the following clinical scenarios:
  - unstable coronary syndromes
  - in conjunction with invasive coronary catheterization
  - for the purpose of screening or disease surveillance
  - within 30 days of a myocardial infarction
  - Current completed and interpreted CCTA documents any of the following results:
    - Normal CCTA

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- CAD-RADS-0
- High-grade stenosis (>70%)
- CAD-RADS 4
- CAD-RADS 5

Note:

See **General Guidelines CD 1.0** for **CAD-RADS** classifications

Evidence Discussion

Coronary Computed Tomography Angiography (CCTA) provides non-invasive anatomic coronary imaging with excellent sensitivity for detecting coronary plaques and stenosis. However, artifacts can significantly lower the specificity, which potentially leads to higher healthcare resource utilization. Notwithstanding this concern, the ability to characterize coronary plaques and stenosis on a CCTA proved to be advantageous over functional stress testing, with respect to diagnostic characteristics and prognostication, as demonstrated by high-quality evidence, including multiple randomized trials.

To ensure a clinically meaningful study, in addition to paying meticulous attention to the scanner functionality and protocol selection, careful individual selection is imperative. Based on the known performance characteristics of CCTA and high-quality clinical trials from Europe and North America, there is general agreement between the American and European guidelines to focus CCTA testing on the following general categories:

- Cardiac chest pain with no known coronary artery disease (CAD)
- Absence of symptoms or possible cardiac chest pain with no known CAD, when objective evidence of cardiac structure or function abnormality is present
- Information about specific coronary artery abnormalities, such as left main coronary stent and bypass graft patency, congenital coronary anomaly, non-atherosclerotic coronary disease may potentially alter clinical management decision.
- CCTA will replace conventional invasive coronary angiography when the likelihood of coronary intervention is not high based on clinical assessment.

CTA derived fractional flow reserve (FFRct) is one of the value-added technologies that have been shown to improve the accuracy of CAD diagnosis over and above CCTA alone. While it modestly adds negative predictive value to CCTA by excluding critical coronary lesion with a FFRct value >0.8, the positive predictive value is inadequate to confer confidence to locate lesions with significant stenosis. Effective adoption of this technology, therefore, is contingent upon ensuring optimal CCTA image quality and a mindful individual selection process; for example, avoid applying FFRct to those with left main coronary disease ≥50% or those with critical triple vessel disease.

Click Here to Return to the Main TOC

Coronary Plaque Analysis (AI-QCT/AI-CPA) using coronary computed tomography angiography (CCTA) is an adjunctive tool used to assess intermediate risk plaque or CAD-RADS1 to CAD-RADS 3 category on CCTA done on individuals with chest pain and no known coronary artery disease. Multiple software have been developed as an adjunct to CCTA to aid in the visualization, characterization, and to improve accuracy of this assessment. This is intended to improve clinical diagnosis and management of CAD.

AI-CPA is currently being used to help stage medical treatment based on severity of plaque and to help predict those who are increased risk for ACS. It has also been shown to be consistent with consistent with invasive fractional flow reserve and intravascular ultrasound (IVUS). It is best used to target those most susceptible to acute coronary syndrome and to guide preventative measures of coronary artery disease.

CT Heart for Evaluation of Cardiac Structure and Morphology (CD-4.6)

CD.CT.0004.6.A
v2.0.2026

CT Cardiac Morphology - Indications

CPT® 75572

- Cardiac vein identification for lead placement in left ventricular pacing
- To evaluate the anatomy of the pulmonary veins prior to a pulmonary vein isolation (ablation) procedure for atrial fibrillation
  - Post-procedure between 3-6 months after ablation

Note:

See also **Initial Transthoracic Echocardiography (TTE) Indications (PEDCD-8.2)**

- If echocardiogram is inconclusive for:
  - cardiac or pericardial tumor or mass
  - cardiac thrombus
  - pericarditis/constrictive pericarditis
  - complications of cardiac surgery
- In place of MRI when there is clinical suspicion of arrhythmogenic right ventricular dysplasia or arrhythmogenic cardiomyopathy (ARVD/ARVC) if the clinical suspicion is supported by established criteria. For ARVD, see **Cardiac MRI – Indications (excluding Stress MRI) (CD-5.2).**
- Recurrent laryngeal nerve palsy due to cardiac chamber enlargement
- Prior to planned valvular interventions (TAVR, TMVR and TTVR) in individuals with radiation-induced valve disease
- CT Cardiac Morphology can be performed instead of TEE for assessment of left atrial appendage (LAA) occlusion device or to assess for thrombus. See: **Transesophageal Echocardiography (TEE) – Indications (CD-2.5).**
  - pre-procedural evaluation
  - repeat imaging 45 days post-procedure
    - Another follow-up study is medically necessary before the 1-year surveillance when the imaging study at 45 days shows a peri-device gap ≥5 mm or Device Related Thrombus usually at 3-6 months.
  - 1 year post-procedure

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Background and Supporting Information

Coronary imaging is not included in the code definition for CPT® 71275.

Repeat testing is medically necessary post pulmonary vein isolation procedure because of a 1%-2% incidence of asymptomatic pulmonary vein stenosis.

CT Heart for Congenital Heart Disease (CD-4.7)

CD.CT.0004.7.A
v2.0.2026

CPT® 75573

- Coronary artery anomaly evaluation
  - A cardiac catheterization was performed, and not all coronary arteries were identified.
- Thoracic arteriovenous anomaly evaluation
  - A MRI Cardiac or CT Angiogram Chest was performed and suggested congenital heart disease.
- Complex adult congenital heart disease evaluation
  - No CT Cardiac or MRI Cardiac has been performed, and there is a contraindication to MRI Cardiac.
  - A CT Cardiac or MRI Cardiac was performed 1 year ago or more.
- See also section **Adult Congenital Heart Disease (CD-11)**.

Transcatheter Aortic Valve Replacement (TAVR) (CD-4.8)

CD.CT.0004.8.A
v2.0.2026

CT Imaging in Transcatheter Aortic Valve Replacement (TAVR)

Pre-TAVR imaging

Pre-aortic valve replacement

- Once the decision has been made for aortic valve replacement, the following may be used to determine if an individual is a candidate for TAVR:
  - CTA Chest (CPT® 71275), Abdomen and Pelvis (combination code CPT® 74174) are medically necessary; and
  - CT Cardiac (CPT® 75572) is medically necessary to measure the aortic annulus; or
  - Coronary CTA (CCTA CPT® 75574) is medically necessary to both measure the aortic annulus and assess the coronary arteries in lieu of heart catheterization.
- A repeat diagnostic left heart catheterization is **not** medically necessary when the individual is undergoing a transcatheter aortic valve replacement (TAVR).

Transfemoral access not feasible

Alternative imaging can be obtained to evaluate vascular access for TAVR in individuals for whom it is documented either via the office note or prior imaging that transfemoral access would not be feasible due to **any** of the following exclusion criteria:

- small vessels
- highly calcified vessels
- stenosed or occluded vessels
- prior aortoiliac vascular intervention

Imaging is medically necessary based on the documented intended access site (transaxillary or transcarotid) and should be of the involved body areas. The following studies are medically necessary based on the documented planned access site:

- CTA of the Head (CPT® 70496) and/or Neck (CPT® 70498) for transcarotid access
- CTA of the Chest (CPT® 71275) and/or Upper Extremity (CPT® 73206) for transaxillary access

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Post-TAVR imaging

CT Cardiac (CPT® 75572) is medically necessary:

- if any of the post-TAVR TTEs are indeterminate or raises a concern about any of the following:
  - valve thrombosis
  - infective endocarditis
  - structural degeneration
- when a Valve-in-Valve implantation or surgical re-do AVR is being contemplated
- Routine CT surveillance or follow up for incidental Hypoattenuated Leaflet Thickening (HALT) with or without restricted leaflet motion, also referred to as Hypoattenuation Affecting Motion (HAM), is NOT medically necessary.

Evidence Discussion

The ability of the cardiac CT technology to provide a tomographic view of the cardiovascular system has resulted in its ubiquitous adoption in the pre-procedure planning for almost all cardiac structural interventions. Specifically, cardiac CT circumvents the image window limitation of echocardiography, allows high definition visualization of the posterior structures, and facilitates pre-procedural planning for pulmonary vein isolation, coronary sinus pacer leads insertion, and left atrial appendage occlusion device implantation, among other trans-catheter structural interventions.

In non-interventional settings, cardiac CT provides an alternative to cardiac MRI when structural information cannot be adequately obtained by an echocardiography. Most notably, the evaluation of a cardiac mass, extent of pericardial disease, complex congenital heart disease and cardiomyopathy, can be performed by a cardiac CT when cardiac MRI is not available or contraindicated.

Trans-catheter Aortic Valve Replacement (TAVR)

The success of a Trans-catheter Aortic Valve Replacement (TAVR) procedure is contingent upon a meticulous pre-TAVR planning imaging study where cardiac CT allows accurate annulus sizing, coronary heights measurement, and calcification distribution evaluation, in addition to access site planning. Post-operatively, clinically suspected complications such as thrombus formation, infective endocarditis, or structural degeneration can be confirmed on a cardiac CT; a routine surveillance strategy, however, is not supported because of unclear or even potentially harmful outcome of treating incidental findings.

Transcatheter Mitral Valve Repair (mitral valve clip)

In non-interventional settings, cardiac CT provides an alternative to cardiac MRI when structural information cannot be adequately obtained by an echocardiography. Most notably, the evaluation of a cardiac mass, extent of pericardial disease, complex

Proprietary Information of UnitedHealthcare.

congenital heart disease and cardiomyopathy, can be performed by a cardiac CT when cardiac MRI is not available or contraindicated. Percutaneous treatment of mitral regurgitation can be accomplished using venous access to apply a clip device (e.g., MitraClip currently FDA approved) to provide edge-to-edge mitral leaflet coaptation, approximating opposing sections of the anterior and posterior mitral valve leaflets. FDA approved indications include treatment for individuals with symptomatic, moderate to severe, or severe primary mitral regurgitation whose surgical risks are prohibitive, as well as symptomatic moderate to severe or severe secondary mitral regurgitation who have failed optimal medical therapy. This therapy should include, if medically necessary, cardiac resynchronization therapy.

Transcatheter Mitral & Tricuspid Valve Replacement

Transcatheter Tricuspid Valve Replacement device (EVOQUE) is currently FDA approved. In individuals being considered for transcatheter tricuspid or mitral valve replacement, Cardiac CT (CPT® 75572) provides detailed imaging of the valve annulus including measurement of valve annulus to guide selection of the appropriate-sized valve. CTV Chest (CPT® 71275) and CTV Abdomen and Pelvis (CPT® 74174) provide imaging of the iliac veins and inferior vena cava to exclude stenosis or significant tortuosity and aid in determining eligibility and procedure planning.

3D Predictive Model Generation for Pre-planning of Cardiac Procedure (CD-4.9)

CD.CT.0004.9.A
v2.0.2026

Coding

Description	HCPCS
3D predictive model generation for pre-planning of a cardiac procedure, using data from cardiac computed tomographic angiography with report	C9793

Criteria

3D predictive model generation for pre-planning of a cardiac procedure, using data from cardiac computed tomographic angiography is considered to be experimental, investigational, or unproven.

Evidence Discussion

Cardiac Computed Tomography Angiography is a 3D imaging acquisition, viewing, and reporting system. Standard Cardiac Computed Tomography Angiography includes the viewing of 3D images. Currently, there is not enough data to support the use of 3D predictive model generation for pre-planning of cardiac procedures. It has not been shown to improve outcomes when compared with standard Cardiac Computed Tomography Angiography.

Cardiac MRI and Cardiac Indications for MRA Chest (CD-5.2)

CD.MRI.0005.2.A
v2.0.2026

Cardiac MRI – Coding

Cardiac Imaging Procedure Codes

Cardiac MRI	CPT®/HCPCS
Cardiac magnetic resonance imaging for morphology and function without contrast	75557
Cardiac magnetic resonance imaging for morphology and function without and with contrast and further sequences	75561
Cardiac magnetic resonance imaging for velocity flow mapping (List separately in addition to code for primary procedure)	+75565
Cardiac magnetic resonance imaging for morphology and function, quantification of segmental dysfunction; with strain imaging	C9762

- Only 1 procedure code from the set (CPT® 75557-CPT® 75563) should be reported per session.
- Only 1 flow velocity measurement (CPT® +75565) should be reported per session when medically necessary.

Cardiac MRI and Cardiac Indications for MRA Chest

Indications (excluding Stress MRI)

- Assess myocardial viability (to differentiate hibernating myocardium from scar) when necessary to determine if revascularization should be performed (CPT® 75561)
- Assessment of global ventricular function, myocardial composition, and mass if a specific clinical question is left unanswered by a recent echocardiogram and results will affect individual management (CPT® 75557 or CPT® 75561). Particularly useful in evaluating:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- cardiomyopathy (ischemic, diabetic, hypertrophic, or muscular dystrophy)
- non-compaction
- infiltrative heart disease such as amyloidosis and sarcoidosis (see also **Cardiac Sarcoidosis (CD-3.9)**)
- post cardiac transplant
- hypertrophic cardiomyopathy
- suspected acute myocarditis, cardiac aneurysm, trauma, and contusions
- monitoring cancer chemotherapy effect on the heart (especially if an accurate assessment of right ventricular function is documented as necessary)

- Pre- and post-operative congenital heart disease assessment. See **Adult Congenital Heart Disease (CD-11)** for defect specific indications (CPT® 75557 or 75561).
  - MRA Chest (CPT® 71555) may be added if the aorta or pulmonary artery need to be visualized beyond the root.
  - May add CPT® +75565 in conjunction with CPT® 75557 or 75561, only if there is a need to clarify findings on a recent echocardiogram and cardiac Doppler study when there is documentation of **either** of the following:
    - significant valvular disease that may require intervention
    - intracardiac flow disturbances (e.g., ASD, VSD)
- MRA Chest (CPT® 71555) is medically necessary for the following:
  - Thoracic aortic dissection. See **Aortic Dissection and Other Aortic Conditions (PVD-6.7)** in the Peripheral Vascular Disease Imaging Guidelines.
  - Coarctation of the aorta. See:
    - **Coarctation of the Aorta (CD-11.3.2)** for adults
    - **Aortic Coarctation and IAA (interrupted aortic arch) (PEDCD-2.4.11)** for infants and children in the Pediatric Cardiac Imaging Guideline
  - Thoracic aortic aneurysm. See **Thoracic Aortic Aneurysm (TAA) (PVD-6.2)** in the Peripheral Vascular Disease Imaging Guidelines.
- Coarctation of the aorta
  - For adults, see **Coarctation of the Aorta (CD-11.3.2)**.
    - For infants and children, see **Aortic Coarctation and IAA (interrupted aortic arch) (PEDCD-2.4.11)** in the Pediatric Cardiac Imaging Guideline.
- Assessment of ventricular arrhythmia for ablation planning (CPT® 75557 or 75561)
- Assessment of arrhythmogenic left ventricular cardiomyopathy (ALVC) (CPT® 75557 or 75561)
- Arrhythmogenic right ventricular dysplasia or arrhythmogenic right ventricular cardiomyopathy (ARVD/ARVC) suspicion (CPT® 75557 or 75561) must have one of the following:
  - non-sustained or sustained VT of LBBB morphology OR >500 PVCs over 24 hours on event recorder or Holter monitor

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - ARVD/ARVC confirmed in a first-degree relative either by criteria, autopsy, pathogenic genetic mutation or sudden death <35 years of age with suspected ARVD/ARVC
  - inverted T waves in right precordial leads (V1, V2 and V3) or beyond in individuals >14 years of age in the absence of complete RBBB
  - right ventricular akinesis, dyskinesis, or aneurysm noted on echo or RV angiography
- Differentiate constrictive pericarditis from restrictive cardiomyopathy (CPT® 75561)
- Evaluate cardiac tumor or mass when echocardiogram is inconclusive (CPT® 75557 or 75561)
- Evaluate valvular heart disease when echocardiogram is inconclusive:
  - CPT® 75557 **or** CPT® 75561
  - May add CPT® 75565 when there is documentation of either of the following:
    - significant valvular disease that may require intervention
    - intracardiac flow disturbances (e.g., ASD, VSD)
- MRI Cardiac (CPT® 75557 or 75561) **or** chest MRV (CPT® 71555), but not both, for pulmonary vein anatomy for planned ablation procedures in individuals with atrial fibrillation. See **Pulmonary Vein Imaging – Indications (CD-8.2)** for guidelines on follow-up imaging after ablation procedure.
- Suspected cardiac thrombus when echocardiogram is inconclusive (CPT® 75557).
- Right ventricular function evaluation (CPT® 75557 in conjunction with CPT® +75565) if there has been a recent ECHO and there is documented need to perform Cardiac MRI in order to resolve an unanswered question about flow dynamics
- Cardiac MRI (CPT® 75557 or 75561) and CMR velocity flow mapping (CPT® 75565) for preoperative evaluation prior to planned LVAD implant
- Shunting through a VSD (CPT® 75557 in conjunction with CPT® +75565) if a recent ECHO has been done, including a bubble study, and there is documented need to perform Cardiac MRI in order to resolve an unanswered question about flow dynamics
- Conditions that would **not** require an ECHO prior to an MRI:
  - detect anomalous coronary arteries (CPT® 75561)
  - assess coronary arteries in Kawasaki disease
  - Fabry disease (CPT® 75561)
  - initial evaluation for cardiac sarcoidosis or iron overload cardiomyopathy (hemosiderosis, hemochromatosis)

Non-indications

C9762-Cardiac magnetic resonance imaging for morphology and function, quantification of segmental dysfunction; with strain imaging. The use of CMR strain imaging for the

Click Here to Return to the Main TOC

quantification of segmental dysfunction is considered investigational and experimental at this time.

Quantitative analysis of myocardial tissue composition by MRI (CPT® codes 0648T, 0649T, 0697T and 0698T) are considered experimental, investigational, or unproven at this time. There is insufficient clinical data to support their use.

Cardiac MRI – Aortic Root and Proximal Ascending Aorta

- See **Thoracic Aortic Aneurysm (TAA) (PVD-6.2)** in the Peripheral Vascular Disease imaging guidelines.

Cardiac MRI – Duchenne Muscular Dystrophy (DMD)

Cardiac MRI (CPT® 75557 or 75561-does not include CPT® 75565 or 71555 unless otherwise indicated)

- Asymptomatic individual with documented DMD can have annual surveillance cardiac MRI starting at 6 years old (yearly echo is recommended prior to age 6)
- Asymptomatic, documented carrier of DMD can have cardiac MRI every 3 years starting at 18 years

Cardiac MRI – Evaluation of Pericardial Effusion or Diagnosis of Pericardial Tamponade

- Contrast-enhanced cardiac MRI (CPT® 75561) is useful for evaluating pericarditis, neoplastic, and other effusion, tamponade, or myocardial infiltration if a specific clinical question is left unanswered by echocardiogram or another recent imaging study.

Cardiac MRI – Myocarditis

Clinical evaluation of suspected myocarditis

Initial testing for suspected myocarditis should consist of an electrocardiogram, measurement of cardiac troponin, and an echocardiogram.

Cardiac MRI (CPT® 75561) is medically necessary for suspected myocarditis in the presence of **all** of the following:

- New onset or persisting symptoms suggestive of myocarditis documented by **any** of the following:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - dyspnea
  - chest pain
  - palpitations
  - syncope
  - effort intolerance
- Evidence for recent or ongoing myocardial injury documented by **any** of the following results on initial screening:
  - ventricular dysfunction noted on any cardiac imaging study, or
  - new or persisting ECG abnormalities suspicious for myocarditis
    - ST changes, T wave changes, Q waves, or
    - conduction abnormalities, such as LBBB or AV block, or
    - VT or VF
  - elevated troponin
- Strong suspicion for viral etiology of myocardial injury with documentation of **both**:
  - recent systemic viral disease, recent mRNA COVID-19 vaccination, or prior myocarditis
  - no evidence of coronary ischemia as documented by **any** of the following:
    - lack of risk factors for CAD
    - age < 35 years
    - negative cardiac imaging study, such as MPI, CCTA, catheterization

Return to Play Screening for athletes at risk for myocarditis

Cardiac MRI (CPT® 75561) is medically necessary for **Return to Play Screening** for athletes when there is documentation of **both** of the following:

- Individual has a history of a clinical condition associated with myocarditis (i.e., COVID-19 infection or recent mRNA COVID-19 vaccination).
- Initial screening has been performed with documentation of **either** of the following:
  - Initial screening (ECG, troponin, and TTE) showed evidence for recent or ongoing myocardial injury (as defined above in Clinical Evaluation of Suspected Myocarditis) with ongoing symptoms concerning for myocarditis (dyspnea, chest pain, palpitations, syncope, or effort intolerance).
  - Normal results of initial screening with persistent or new onset symptoms concerning for myocarditis.

Background and Supporting Information

Evidence Discussion

- Guidelines and appropriate use criteria support the use of transthoracic echocardiogram (TTE) as the initial study for a broad range of cardiac conditions.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

TTE can be used to evaluate cardiac morphology and function and provides information necessary to diagnose and guide treatment in conditions including heart failure and cardiomyopathy, ischemic heart disease, and valvular dysfunction. TTE is also used to initially assess intracardiac and extracardiac structures, including suspected cardiac masses, sources of emboli, and pericardial conditions. TEE visualizes portions of the great vessels and provides initial imaging of these structures.

- TTE has significant advantages over other imaging modalities; it is easily accessible and even portable, provides no exposure to radiation, is inexpensive, and has minimal, if any, risks.
- Like TTE, MRI assesses cardiac morphology and function; additionally, MRI provides information regarding myocardial perfusion, metabolism, and tissue composition.
- When questions remain unanswered after TTE, MRI can provide additional information due to its ability to assess myocardial composition and mass; these characteristics make cardiac MRI especially useful in the settings of cardiomyopathy, non-compaction, infiltrative heart disease, post cardiac transplant, cardiac masses, pericardial disease, and myocarditis.
- Beyond imaging with TTE, MRI can provide improved visualization of valvular pathology, because images are not limited by body habitus, is of high spatial resolution, can more accurately quantify the magnitude of valve insufficiency and stenosis, and can assess the effects of valve dysfunction on ventricular mass or volume. Qualities of MRI that augment evaluation of valvular disease may also improve visualization of intracardiac shunts over TTE alone.
- Advantages of MRI assessment of the great vessels include avoidance of ionizing radiation, provision of excellent spatial resolution of structures, and is not limited by body habitus.
- Conditions that are better evaluated initially by MRI, include coronary artery anomalies, and diseases of abnormal myocardial composition: Arrhythmogenic right ventricular dysplasia, Fabry disease-(Late enhancement MRI may predict the effect of enzyme replacement therapy on myocardial changes that occur with this disease), cardiac sarcoidosis, and Duchenne Muscular Dystrophy.
- When TTE and other less advanced imaging provide the information necessary to diagnose and treat cardiovascular conditions, MRI is not medically necessary.
- Disadvantages of MRI include being less accessible and possibly being incompatible for use in those with implanted devices. The gadolinium contrast agents used in MRI require precautions in those with advanced renal disease and severe liver disease.
- The decision to use MR imaging is made in the context of other testing; duplication of information should be avoided, and more readily available modalities with lower risk, initially considered. An assessment should be made as to whether additional testing will provide complementary diagnostic, therapeutic, or prognostic information that will optimize care.

Cardiac Stress MRI- (CD-5.3)

CD.MRI.0005.3.A
v2.0.2026

Cardiac Stress MRI – Coding

Cardiac Imaging Procedure Codes

Cardiac MRI	CPT®/HCPCS
Cardiac magnetic resonance imaging for morphology and function without contrast; with stress imaging	75559
Cardiac magnetic resonance imaging for morphology and function without and with contrast and further sequences; with stress imaging	75563
Cardiac magnetic resonance imaging for velocity flow mapping (List separately in addition to code for primary procedure)	+75565
Cardiac magnetic resonance imaging for morphology and function, quantification of segmental dysfunction; with stress imaging	C9763
Non-invasive determination of absolute quantitation of myocardial blood flow (AQMBF), derived from augmentative algorithmic analysis of the dataset acquired via contrast cardiac magnetic resonance (CMR), pharmacologic stress, with interpretation and report by a physician or other qualified health care professional (List separately in addition to code for primary procedure)	+0899T
Non-invasive estimate of absolute quantitation of myocardial blood flow (AQMBF), derived from assistive algorithmic analysis of the dataset acquired via contrast cardiac magnetic resonance (CMR), pharmacologic stress, with interpretation and report by a physician or other qualified health care professional (List separately in addition to code for primary procedure)	+0900T

- Only 1 procedure code from the set (CPT® 75557- CPT® 75563) should be reported per session.
- Only 1 flow velocity measurement (CPT® +75565) should be reported per session when medically necessary.

Proprietary Information of UnitedHealthcare.

- C9763-Cardiac magnetic resonance imaging for morphology and function, quantification of segmental dysfunction; with stress imaging. The use of stress CMR for the quantification of segmental dysfunction is considered investigational and experimental at this time.

Indications for Cardiac Stress MRI

Criteria

- If a nuclear perfusion (MPI) stress test was performed and was equivocal, a stress MRI is medically necessary.
- To further evaluate the etiology of myocardial infarction with no obstructive coronary arteries (MINOCA) in the setting of a normal coronary angiogram
- Stress imaging with AQMBF is medically necessary for individuals with suspected or known non-obstructive CAD such as MINOCA (myocardial infarction with no obstructive coronary arteries), INOCA (ischemia with no obstructive coronary arteries), or ANOCA (angina with no obstructive coronary arteries) to evaluate persistent symptoms of chest pain, exertional dyspnea, or exertional fatigue in the setting of any of the following:
  - a normal or equivocal ETT
  - a diagnosis of no obstructive CAD on CCTA or invasive coronary angiography with **either** of the following:
    - persistent symptoms despite medical management (beta-blockers, CCBs, nitrates, ranolazine, and ACE-Is)
    - functional testing demonstrates myocardial ischemia (such as invasive coronary function testing or non-invasive stress testing without AQMBF)

See **Stress Testing with Imaging – Indications (CD-1.4)**. for Indications for Stress MRI

Absolute quantitation of myocardial blood flow (AQMBF)

Non-invasive determination of absolute quantitation of myocardial blood flow (AQMBF) using AI-analysis of data obtained from cardiac magnetic resonance imaging (CMR) with pharmacological stress (CPT® 0899T or 0900T) is medically necessary to further evaluate cardiac function when performed with a cardiac MRI stress (CPT® 75559 or 75563).

Cardiac PET – Absolute Quantitation of Myocardial Blood Flow (AQMBF) (CD-6.3)

CD.PET.0006.3.A
v2.0.2026

Absolute Quantitation of Myocardial Blood Flow (CPT® 78434)

Quantitation of myocardial blood flow at rest and with stress in mL/g/min and the calculation of myocardial perfusion reserve (the ratio of stress to rest flow) can be used for diagnosis and prognosis of coronary artery disease and cardiac endothelial dysfunction that can be seen in diabetes, left ventricular hypertrophy, and heart transplantation vasculopathy, among other conditions.

- AQMBF with PET (CPT® 78434) is an add-on procedure that is medically necessary when one of the following apply:
  - Primary study Myocardial PET rest/stress perfusion (CPT® 78492 or 78431 only) has been approved.
  - Primary study Myocardial PET rest/stress perfusion (CPT® 78492 or 78431 only) has been ordered and is being approved at the same time (see: **Cardiac PET- Perfusion- Indications (CD-6.2)** or **Stress Testing with Imaging- Indications (CD-1.4)**).

Evidence Discussion

Despite its utility, AQMBF is a technically challenging measurement. Variables include:
- Different tracers (N-13 ammonia vs Rb-82 Cl) give different values.
- Different mathematical models are used (static vs dynamic).
- Different stressors are used that give different hyperemic flow results (adenosine vs dipyridamole vs regadenoson).
- Data can be collected in 2D vs 3D modes. Saturation of crystals is more problematic in 3D.
- Cardiac, respiratory, and individual motion can degrade measurement accuracy.
- Different vendor software is used by different reading labs.
- Resting blood flow can be elevated due to pain, anxiety, lack of vagal tone, hypertension, etc. and can be normalized by using the rate pressure product (RPP) for calculation of myocardial perfusion reserve (MBF) the ratio of myocardial hyperemic flow/rest flow.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Evidence Discussion

Myocardial perfusion imaging (MPI) is used for the diagnosis of coronary artery disease (CAD). Results of MPI have a high level of sensitivity and specificity. Positron emission tomography (PET) is one imaging modality that allows the performance of MPI and also has the ability to measure absolute myocardial blood flow (AQMBF) (CPT® 78434) in ml/g/min. This has been shown to add to the diagnosis of CAD and aid in treatment decisions.

As supported by the ACC/AHA Appropriate Use Criteria, the use of MPI with PET is medically necessary for individuals with signs or symptoms that would be consistent with CAD such as typical angina or other typical or atypical symptoms in individuals with known CAD or prior interventions such as coronary artery bypass surgery or coronary stenting. This balances the appropriate testing of individuals with PET versus medically unnecessary and potentially harmful testing and downstream procedures.

Cardiac PET – Metabolic – Indications (CD-6.4)

CD.PET.0006.4.A
v2.0.2026

- Cardiac PET Metabolic and cardiac SPECT or PET perfusion (CPT® 78429 or CPT® 78459 and CPT® 78451, or CPT® 78432, or CPT® 78433)
  - to determine myocardial viability when a previous study has shown significant left ventricular dysfunction when under consideration for revascularization
- To diagnose strongly suspected cardiac sarcoid or monitor response to therapy for established cardiac sarcoid. See **Cardiac Sarcoidosis (CD-3.9)**.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

FDG PET/CT for Infections (CD-6.5)

CD.PET.0006.5.A
v2.0.2026

- FDG PET/CT (CPT® 78815 or CPT® 78429) is medically necessary in the assessment of suspected prosthetic heart valve endocarditis when there is documentation of **both** of the following:
  - TTE and/or TEE are equivocal or non-diagnostic
  - Suspicion for prosthetic heart valve endocarditis remains high (all):
    - C-reactive protein ≥40mg/L
    - no evidence of prolonged antibiotic therapy
    - the implantation was ≥3 months ago and there is no evidence of surgical adhesives used during the valve implantation
- FDG PET/CT for LVAD driveline infection (CPT® 78815 or 78429)
  - Early infection detection for LVAD drivelines is desirable, since once the infection extends to the cannula and pump pocket, eradication becomes difficult. CT findings are nonspecific, and metal device artifacts of the driveline itself affects sensitivity.
  - FDG PET/CT is medically necessary for suspected LVAD infection if other studies and examination remain inconclusive.

Diagnostic Heart Catheterization – Coding Notes (CD-7.2)

CD.DHC.0007.1.A
v2.0.2026

- Cardiac catheterization (CPT® 93451-CPT® 93461) includes all "road mapping" angiography necessary to place the catheters, including any injections and imaging supervision, interpretation, and report.
- Cardiac catheterization (CPT® 93452-CPT® 93461) (for all conditions other than congenital heart disease) includes contrast injections, imaging supervision, interpretation, and report for imaging typically performed.
- Catheter placements in native coronaries or bypass grafts (CPT® 93454-CPT® 93461) include intraprocedural injections for bypass graft angiography, imaging supervision, and interpretation.
- Injection codes CPT® 93563-CPT® 93565 should not be used in conjunction with CPT® 93452-CPT® 93461.
- Codes CPT® 93451-CPT® 93461 do not include contrast injections and imaging supervision, interpretation, and report for imaging that is separately identified by the following specific procedure codes: CPT® 93566, CPT® 93567 and CPT® 93568.
- Separate diagnostic cardiac catheterization codes should only be assigned in conjunction with interventional procedures in the following circumstances:
  - No prior or recent diagnostic catheterization is available to guide therapy.
  - Individual's condition has significantly changed since the last diagnostic catheterization.
  - The treatment plan may be affected.
  - Other vessels may be identified for treatment.
  - Further establishment of a diagnosis from a non-invasive study is necessary.

Diagnostic Left Heart Catheterization (LHC) (CD-7.3)

CD.DHC.0007.3.A
v2.0.2026

LHC – Unstable/Active Coronary Artery Syndromes (CD-7.3.1)

CPT® 93454, 93455, 93458, 93459

Diagnostic Left Heart Catheterization (LHC) is medically necessary for individuals in acute settings or with **active** unstable angina and should be handled as medical emergencies.

- LHC may be medically necessary for new onset, accelerating, or worsening ischemic symptoms suggestive of acute coronary syndrome (ACS) occurring at rest, or with minimal exertion resolving with rest, including:
  - cardiac chest pain (typical angina) with or without new onset, evolving ischemic EKG changes
  - symptoms consistent with the known angina pattern in an individual with a history of CABG or PCI
- Left and right heart catheterization (CPT® 93460 or 93461) is considered medically necessary in place of a left heart catheterization when criteria has been met for a left heart catheterization and there is documentation of **any** of the following conditions:
  - The major component of the individual's symptoms is dyspnea
  - Newly diagnosed or worsening cardiomyopathy

Stable Established CAD Post Revascularization with CABG or PCI (CD-7.3.2)

CPT® 93454, 93455, 93458, 93459

Note: These guidelines apply to individuals with stable conditions and who are not in the acute setting (acute coronary syndrome or unstable angina).

- Diagnostic Left Heart Catheterization (LHC) is medically necessary in individuals with established Coronary Artery Disease (CAD) post revascularization by percutaneous coronary intervention (PCI) or coronary artery bypass graft surgery (CABG) when there is documentation of **one** of the following:
  - new, recurrent, or worsening ischemic symptoms similar to prior ischemic episode

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- new, recurrent, or worsening cardiac chest pain as defined in **General Guidelines (CD-1.0)**
- new, recurrent, or worsening symptoms of chest pain, exertional dyspnea, or exertional fatigue AND intermediate or high-risk findings on non-invasive stress testing as documented by one of the following:
  - cardiac chest pain induced by exercise treadmill testing or dobutamine stress testing
  - exercise treadmill testing inducing any of the following:
    - at least 1mm horizontal or downsloping ST-depression
    - at least 1mm ST-elevation in two leads
    - ventricular tachycardia of at least 3 consecutive beats
  - myocardial perfusion imaging (SPECT or PET) with ≥5% reversible ischemic burden
  - stress echo with at least 2 segments of inducible ischemia
  - severe stress induced left ventricular dysfunction (drop in left ventricular ejection fraction with stress ≥10%)
- new left ventricular systolic dysfunction (left ventricular ejection fraction <50%)
- worsening left ventricular systolic dysfunction (decline in left ventricular ejection fraction ≥10%)
- new or worsened congestive heart failure
- ventricular fibrillation
- sustained ventricular tachycardia

- Left and right heart catheterization (CPT® 93460 or 93461) is considered medically necessary in place of a left heart catheterization when criteria has been met for a left heart catheterization and there is documentation of **any** of the following conditions:
  - The major component of the individual's symptoms is dyspnea
  - Newly diagnosed or worsening cardiomyopathy

Stable Symptomatic Suspected or Established Coronary Artery Disease (CD-7.3.3)

CPT® 93454, 93455, 93458, 93459

For the purpose of this guideline, cardiac chest pain is defined in **General Guidelines (CD-1.0)**.

- Diagnostic left heart catheterization to screen for coronary artery disease (CAD) in asymptomatic individuals who are not anticipating other cardiac procedures is **not** considered medically necessary.
- LHC with coronary arteriography (CPT® 93454, 93455, 93458, or 93459) is medically necessary when there is documentation of one of the following:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- New onset, persistent, or worsening of cardiac chest pain symptoms and either:
  - Symptomatic failure of a 12 week trial of OMT including as tolerated all of the following:
    - anti-platelet therapy
    - statin and/or other lipid-lowering therapy
    - anti-anginal therapy implemented to pursue a goal heart rate of 60 beats per minute or less
    - anti-hypertensive therapy as may be indicated to pursue a goal systolic blood pressure (SBP) of <140mmHg and a goal diastolic blood pressure (DBP) of <90mmHg
  - Worsening of cardiac chest pain symptoms during 12 week trial of OMT
  - inconclusive stress imaging
- New onset, persistent, or worsening of cardiac chest pain symptoms and documentation of **one** of the following:
  - Established CAD per **General Guidelines (CD-1.0)** or age ≥50 years and/or ≥2 CAD risk factors: diabetes mellitus, smoking, family history of premature CAD, hypertension, dyslipidemia, or
  - Cardiac chest pain at a low level of exercise or at rest despite optimal medical therapy
- LHC is medically necessary irrespective of OMT for symptomatic (chest pain or dyspnea on exertion or exertional fatigue) individuals who also have high-risk findings on Coronary CT Angiography (See **CCTA-Indications for CCTA (CD-4.3))**to include any of the following:
  - left main coronary artery stenosis ≥40%
  - proximal or mid left anterior descending coronary artery stenosis ≥70%
  - proximal or mid double-vessel major epicardial (not branch) coronary artery stenosis ≥60%
  - proximal or mid triple-vessel major epicardial (not branch) coronary artery stenosis ≥50%
  - CT-FFR measured to be ≤0.8 in the proximal or mid segment of any coronary artery or major epicardial branch irrespective of degree of stenosis
- LHC may be medically necessary irrespective of OMT for symptomatic (chest pain or dyspnea on exertion) individuals who have high-risk findings on non-invasive stress testing including any of the following:
  - cardiac chest pain induced by exercise treadmill testing or dobutamine stress testing
  - myocardial perfusion imaging with ≥10% reversible ischemic burden
  - stress echo with at least 3 segments of inducible ischemia
  - exercise treadmill testing inducing at least 2.5 mm downsloping ST-depression or 3mm horizontal ST-depression in two leads

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

        - ventricular tachycardia of at least 3 consecutive beats induced by an exercise treadmill test
    - LHC is medically necessary if coronary artery disease is the suspected etiology for **any** of the following findings:
        - new or worsened congestive heart failure
        - new left ventricular systolic dysfunction (left ventricular ejection fraction <50%)
        - worsening left ventricular systolic dysfunction (decline in left ventricular ejection fraction ≥10%)
        - ventricular fibrillation or sustained ventricular tachycardia
- Left and right heart catheterization (CPT® 93460 or 93461) is considered medically necessary in place of a left heart catheterization when criteria has been met for a left heart catheterization and there is documentation of **any** of the following conditions:
    - The major component of the individual's symptoms is dyspnea
    - Newly diagnosed or worsening cardiomyopathy

Background and Supporting Information

In addition to OMT, physician-guided behavioral modification therapy (BMT) is medically necessary including all of the following:

- Mediterranean diet
- Moderate intensity physical activity for at least thirty minutes per day at least five times per week as possible
- Attempts at smoking cessation to include at least one of the following:
    - Cognitive behavioral therapy
    - Nicotine withdrawal replacement therapy

Inconclusive stress imaging

- for stress echo
    - 3 or more dysfunctional segments of the 16 segments during stress
- for stress CMR
    - 4 or more 32 subsegments with ischemic perfusion defects during vasodilation stress OR
    - 3 of 16 segments with new or worsened dysfunction during exercise stages or progressive inotropic stress

Exclusion of Significant Coronary Artery Disease Involvement in Other Cardiac Pathology (CD-7.3.4)

CPT® 93454, 93455, 93458, 93459

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- LHC is medically necessary when the etiology is unclear for **any** of the following conditions when coronary artery disease is suspected:
  - new or worsened congestive heart failure
  - new left ventricular systolic dysfunction (left ventricular ejection fraction <50%)
  - worsening left ventricular systolic dysfunction (decline in left ventricular ejection fraction ≥10%)
  - ventricular fibrillation or sustained ventricular tachycardia
  - unheralded syncope (not near syncope)
  - suspected myocarditis
  - CCTA findings with high risk findings such as:
    - left main disease with ≥50% stenosis
    - three-vessel disease with ≥70 stenosis
    - two-vessel disease with ≥70% stenosis, including the proximal LAD
    - one-vessel disease of the proximal LAD with ≥70% stenosis and FFR-CT ≤0.8
- Left and right heart catheterization (CPT® 93460 or 93461) is considered medically necessary in place of a left heart catheterization when criteria has been met for a left heart catheterization and there is documentation of **any** of the following conditions:
  - The major component of the individual's symptoms is dyspnea
  - Newly diagnosed or worsening cardiomyopathy

Evaluation of Structural Heart Disease (CD-7.3.5)

CPT® 93454, 93455, 93458, 93459

Left heart catheterization with coronary arteriography is medically necessary for any of the following:

- Evaluation prior to planned invasive procedure or surgery
  - Ruling out coronary artery disease prior to planned non-coronary cardiac or great vessel surgery including any of the following:
    - cardiac valve surgery
    - surgical myectomy for hypertrophic cardiomyopathy
    - aortic dissection
    - aortic aneurysm
    - congenital disease repair such as atrial septal defect
  - Pre-organ transplant (non-cardiac)-in place of stress imaging for initial pre-transplant evaluation (per the transplant center's protocol) **or** if stress imaging is positive for ischemia. Repeat periodic screening while on a transplant waiting list (in the absence of other clinical indications) is not medically necessary. See **Kidney Transplant, Pre-Transplant Imaging Studies (AB-42.5)**.
  - Prior to catheter ablation of ventricular arrhythmia at one of the following sites:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

    - sinus of Valsalva
    - coronary venous system
    - epicardium
- Valvular heart disease when either:
  - There is a discrepancy between the clinical findings (history, physical exam, and non-invasive test results).
  - Valvular surgery is being considered.
- Suspected pericardial disease
- Previous cardiac transplant:
  - per transplant center protocol
  - to assess for accelerated coronary artery disease associated with cardiac transplantation

Left and right heart catheterization (CPT® 93460 or 93461) is considered medically necessary in place of a left heart catheterization when criteria has been met for a left heart catheterization and there is documentation of **any** of the following conditions:

- The major component of the individual's symptoms is dyspnea
- Newly diagnosed or worsening cardiomyopathy

Evidence Discussion

Medical specialty organization guidelines recommend guideline directed medical therapy as the cornerstone of management of chronic coronary artery disease. These recommendations are based on a large body of evidence; including multiple large randomized controlled clinical trials (COURAGE, ISCHEMIA, and BARI-2D), and meta-analyses that demonstrate a significant improvement in angina symptoms, and cardiac events with guideline directed medical therapy. These trials further demonstrate that there is no improvement in survival or cardiac events with routine revascularization compared to guideline directed medical therapy.

Management options for coronary artery disease should account for the risks of invasive coronary angiography weighed against the benefits. Invasive coronary angiography is associated with cardiac (e.g., coronary artery injury and myocardial infarction) and extra-cardiac (e.g., vascular access site bleeding, ischemic stroke, and contrast-mediated acute kidney injury) risks. Invasive coronary angiography should be utilized as the treatment option when there is a favorable benefit-to-risk assessment.

Based on medical specialty organization guidelines and Appropriate Use Criteria, indications for invasive coronary angiography include the following:

- angina despite guideline directed medical therapy
- angina with high-risk findings on stress testing
- new left ventricular systolic dysfunction or heart failure of suspected ischemic etiology

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- known coronary artery disease with prior revascularization with recurrent angina
- prior to non-coronary cardiac surgery, major vascular surgery, or organ transplant

  In addition to OMT, physician-guided behavioral modification therapy (BMT) is recommended including all of the following:
  - Mediterranean diet
  - Moderate intensity physical activity for at least thirty minutes per day at least five times per week as possible
  - Attempts at smoking cessation to include at least either cognitive behavioral therapy or nicotine withdrawal replacement therapy

Angiography-Derived Fractional Flow Reserve (CD-7.3.6)

Coding

Description	HCPCS
Catheter placement in coronary artery(s) for coronary angiography, including intraprocedural injection(s) for coronary angiography, imaging supervision and interpretation with left heart catheterization including intraprocedural injection(s) for left ventriculography, when performed and intraprocedural coronary fractional flow reserve (FFR) with 3D functional mapping of color-coded FFR values for the coronary tree, derived from coronary angiogram data, for real-time review and interpretation of possible atherosclerotic stenosis(es) intervention	C7557

Criteria

Angiography-Derived Fractional Flow Reserve based on three-dimensional reconstruction of angiographic images is considered to be experimental, investigational, or unproven.

Background and Supporting Information

Fractional flow reserve (FFR) is an index of the physiological significance of a coronary artery stenosis. It is derived by using a coronary artery pressure guidewire to measure the distal coronary artery pressure. Angiography-Derived Fractional Flow Reserve is an alternative approach to derive FFR without the use of a coronary artery pressure guidewire, based on 3D reconstruction of angiographic images. Mathematical modeling based on hemodynamic laws is then applied to the 3D reconstruction to derive the pressure dynamics along the coronary artery, with results displayed in a color-coded map. Further research is needed to evaluate the accuracy and applicability of Angiography-Derived Fractional Flow Reserve.

Right Heart Catheterization and Right and Left Heart Catheterization without Coronary Angiography (CD-7.4)

CD.DHC.0007.4.A
v2.0.2026

- Diagnostic right heart catheterization (CPT® 93451) OR Diagnostic right and left heart catheterization without coronary angiography (CPT® 93453) is medically necessary when results will impact the diagnosis and management of **any** of the following:
  - atrial septal defect (ASD) including shunt detection and quantification
  - ventricular septal defect (VSD) including shunt detection and quantification
  - patent foramen ovale (PFO)
  - anomalous pulmonary venous return
  - congenital defects including persistent left vena cava
  - pulmonary hypertension
  - pericardial diseases
  - valvular disease
  - right heart failure
  - left heart failure
  - newly diagnosed or worsening cardiomyopathy
  - preoperative evaluation for valve surgery
  - during a left heart catheterization where the etiology of the symptoms remains unclear
  - pre-lung transplant to assess pulmonary pressures
  - pre-liver transplant to assess pulmonary pressures
  - uncertain intravascular volume status with an unclear etiology
  - prior to LVAD implant and post LVAD implant as needed for hemodynamic assessment to guide changes to therapy
  - assessment post-cardiac transplant
    - for routine endomyocardial biopsy
    - assess for rejection
    - assess pulmonary artery pressure
    - can be done per the institution protocol or anytime organ rejection is suspected and biopsy is needed for assessment
  - evaluation of right ventricular morphology.
  - suspected arrhythmogenic right ventricular dysplasia.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Evidence Discussion

General information RHC (CPT® 93451)

- It is performed most commonly from the femoral vein, less often through the subclavian, brachial, or internal jugular vein and inter-atrial septal puncture approach.
- It includes a full oximetry for detection and quantification of shunts.
- Cardiac outputs are calculated by several techniques including the Fick thermodilution.
- Diagnostic right heart catheterization or right and left heart catheterization is performed for functional hemodynamic evaluation and may be combined with cardiac angiography for structural cardiac imaging and coronary angiography for anatomical evaluation of the coronary arteries. Diagnostic right heart catheterization or right and left heart catheterization is medically necessary in selected situations to obtain specific clinical information required for management decisions if it was not provided by non-invasive evaluation. This may be medically necessary in selected situations for management of valvular heart disease, myocardial disease, pericardial disease, congenital heart disease, pulmonary hypertension, heart failure, and post-cardiac transplantation. These indications are addressed in established evidence-based medical specialty organization guidelines pertaining to these conditions. If the clinical information required for management decisions was already provided by non-invasive evaluation, diagnostic heart catheterization does not add to management and, moreover, carries cardiac and extra-cardiac risks including coronary artery injury, myocardial infarction, vascular access site bleeding, ischemic stroke, and contrast-mediated acute kidney injury.

Combined Right and Left Heart Catheterization Indications (CD-7.5)

CD.DHC.0007.5.A
v2.0.2026

Combined Right and Left Heart Catheterization (CPT® 93460 or 93461) is medically necessary for pre-operative surgical planning for any of the following procedures:

- heart valve surgery
- congenital heart defect repair
- lung transplant
- liver transplant

Background and Supporting Information

- Left and right heart catheterization (CPT® 93460 or 93461) is considered medically necessary in place of a left heart catheterization when criteria has been met for a left heart catheterization and there is documentation of **any** of the following conditions:
  - The major component of the individual's symptoms is dyspnea
  - Newly diagnosed or worsening cardiomyopathy

Note:

See the individual diagnostic heart catheterization sections for more information.

Planned (Staged) Coronary Interventions or Invasive Physiologic Evaluation (CD-7.6)

CD.DHC.0007.6.A
v2.0.2026

Planned (Staged) Coronary Interventions

A repeat diagnostic left heart catheterization is not medically necessary when the individual is undergoing a planned staged percutaneous coronary intervention

- The CPT® codes for percutaneous coronary interventions (PCI) include the following imaging services necessary for the procedure(s):
  - contrast injection, angiography, 'road-mapping', and fluoroscopic guidance
  - vessel measurement
  - angiography following coronary angioplasty, stent placement, and atherectomy
- Separate codes for these services should not be assigned in addition to the PCI code(s) because the services are already included.

Invasive Physiologic Evaluation CPT® 93454

Coronary angiography is medically necessary for symptomatic individuals with nonobstructive CAD when requested as part of invasive coronary physiologic testing to guide treatment.

Evidence Discussion

Diagnostic cardiac catheterization with coronary angiography is performed prior to an interventional percutaneous coronary intervention (PCI) procedure. PCI may be performed on the same day as the diagnostic coronary angiogram (ad-hoc PCI) or on a later day (planned staged PCI). Diagnostic coronary angiogram is required only once prior to the interventional procedure. A repeat diagnostic coronary angiogram is not medically necessary prior to a planned staged percutaneous coronary intervention. A repeat diagnostic coronary angiogram does not add to the findings of the initial diagnostic coronary angiogram and, moreover, carries cardiac and extra-cardiac risks including coronary artery injury and myocardial infarction, vascular access site bleeding, ischemic stroke, and contrast-mediated acute kidney injury.

Planned (Staged) Coronary Interventions applies to individuals with clinically stable symptoms if there is documentation of a recent diagnostic catheterization finding of a significant lesion that was not intervened as part of the initial procedure and the

Evaluation of Conditions Other than Coronary Artery Disease (CD-7.7)

CD.DHC.0077.A
v2.0.2026

- Right and left heart catheterization (CPT® 93453) is medically necessary for any of the following:
  - preoperative assessment prior to planned valvular surgery
  - evaluation of pulmonary hypertension out of proportion to or unexplained by the severity of valvular disease documented by other non-invasive imaging modalities (i.e., echo, CMR)
  - left ventricular dysfunction out of proportion to the severity of valvular disease documented by other non-invasive imaging modalities
  - suspected pericardial tamponade as documented by clinical findings or other non-invasive imaging modalities
  - suspected, or clinical uncertainty, between constrictive pericarditis versus restrictive cardiomyopathy physiology when there are questions left unanswered by other cardiac non-invasive imaging modalities
  - known or suspected cardiomyopathy with or without heart failure documented by prior advanced imaging
  - re-evaluation of known cardiomyopathy for any of the following:
    - change in clinical status
    - change in cardiac exam
    - when required to guide therapy
  - hypertrophic cardiomyopathy
  - subvalvular aortic stenosis
- Right and left heart catheterization (CPT® 93453) is medically necessary when there is uncertainty between clinical impression and other non-invasive imaging modalities to evaluate the following valvular diseases:
  - mitral stenosis
  - mitral regurgitation
  - aortic stenosis
  - aortic regurgitation
- Left heart catheterization (CPT® 93452) for hemodynamic evaluation of the left ventricle and aorta is medically necessary to evaluate aortic stenosis when there is uncertainty between the clinical impression and non-invasive imaging modality findings.

Evidence Discussion

Diagnostic right heart catheterization or right and left heart catheterization is performed for functional hemodynamic evaluation and may be combined with cardiac angiography for structural cardiac imaging and coronary angiography for anatomical evaluation of the coronary arteries. Diagnostic right heart catheterization or right and left heart catheterization is medically necessary in selected situations to obtain specific clinical information required for management decisions if it was not provided by non-invasive evaluation. This may be medically necessary in selected situations for management of valvular heart disease, myocardial disease, pericardial disease, congenital heart disease, pulmonary hypertension, heart failure, and post-cardiac transplantation. These indications are addressed in established evidence-based medical specialty organization guidelines pertaining to these conditions. If the clinical information required for management decisions was already provided by non-invasive evaluation, diagnostic heart catheterization does not add to management and, moreover, carries cardiac and extra-cardiac risks including coronary artery injury, myocardial infarction, vascular access site bleeding, ischemic stroke, and contrast-mediated acute kidney injury.

Congenital Heart Disease – General Information (CD-11.1)

CD.CHD.0011.1.A
v2.0.2026

- This section covers adult congenital heart disease (CHD). For other associated disorders, please see the condition specific sections.
  - Marfan Syndrome
  - Hypertrophic cardiomyopathy (HCM)
  - Bicuspid aortic valve (BAV)

Definitions (CD-11.1.1)

Physiological stages (A, B, C, D)

Each congenital heart lesion is divided into 4 physiological stages (A, B, C, D).

Characteristics	Physiological stage			
	A	B	C	D
NYHA functional class	I	II	III	IV
Hemodynamic or anatomic sequelae	None	Mild ventricular enlargement of dysfunction, small shunt	Moderate or greater, ventricular dysfunction. Any venous or arterial stenosis	Moderate or greater, ventricular dysfunction. Any venous or arterial stenosis
Valvular	None	Mild	Moderate or greater	None
Aortic enlargement	None	Mild	Moderate	Severe

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Characteristics	Physiological stage			
	A	B	C	D
Exercise capacity limitation	Normal	Abnormal objective cardiac limitation	Moderate	Severe
Renal hepatic pulmonary dysfunction	None	None	Mild but responsive to medication	Refractory to treatment
Cyanosis/ hypoxemia	None	None	Mild	Severe
Arrhythmias	None	Arrhythmia not requiring treatment	Needs medical therapy	Refractory to medical therapy
Pulmonary hypertension	None	None	Mild to moderate	Severe or Eisenmenger

- CHD Anatomic classification
  - Class I-Simple
    - Native disease
      - isolated small ASD
      - isolated small VSD
      - mild isolated pulmonic stenosis
    - Repaired conditions
      - previously ligated or occluded ductus arteriosus
      - repaired secundum ASD or sinus venosus defect without significant residual shunt or chamber enlargement
      - repaired VSD without significant residual shunt or chamber enlargement
  - Class II-Moderate Complexity
    - Repaired or unrepaired conditions
      - aorto-left ventricular fistula
      - anomalous pulmonary venous connection, partial or total
      - anomalous coronary artery arising from the pulmonary artery
      - anomalous aortic origin of a coronary artery from the opposite sinus

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

    - AVSD (partial or complete, including primum ASD)
    - congenital aortic valve disease
    - congenital mitral valve disease
    - coarctation of the aorta
    - Ebstein anomaly (disease spectrum includes mild, moderate, and severe variations)
    - infundibular right ventricular outflow obstruction
    - ostium primum ASD
    - moderate and large unrepaired secundum ASD
    - moderate and large persistently patent ductus arteriosus
    - pulmonary valve regurgitation (moderate or greater)
    - pulmonary valve stenosis (moderate or greater)
    - peripheral pulmonary stenosis
    - sinus of Valsalva fistula/aneurysm
    - sinus venosus defect
    - subvalvular aortic stenosis (excluding HCM; HCM not addressed in these guidelines)
    - supravalvular aortic stenosis
    - straddling atrioventricular valve
    - repaired tetralogy of Fallot
    - VSD with associated abnormality and/or moderate or greater shunt
- Class III-Great Complexity (or Complex)
    - cyanotic congenital heart defect (unrepaired or palliated, all forms)
    - double-outlet ventricle
    - Fontan procedure
    - interrupted aortic arch
    - mitral atresia
    - single ventricle (including double inlet left ventricle, tricuspid atresia, hypoplastic left heart, any other anatomic abnormality with a functionally single ventricle)
    - pulmonary atresia (all forms)
    - TGA (classic or d-TGA; CCTGA or l-TGA)
    - truncus arteriosus
    - other abnormalities of atrioventricular and ventriculoarterial connection (i.e., crisscross heart, isomerism, heterotaxy syndromes, ventricular inversion)

Modalities (CD-11.1.2)

- Echocardiogram-transthoracic (TTE) or transesophageal (TEE)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Transthoracic echocardiography (TTE) is an indispensable tool in the initial and serial follow-up evaluation to identify abnormalities and changes that commonly influence management decisions.
- Cardiac MRI (CMR)
  - CMR plays a valuable role in assessment of RV size and function, because it provides data that are reproducible and more reliable than data obtained with alternative imaging techniques.
  - For intracardiac congenital heart disease, CMR will typically include flow velocity mapping for shunts and flow assessment.
  - Imaging that only requires aortic arch imaging, does not require intracardiac CMR, only MRA Chest.
- Cardiac Computed Tomography (CCT) and Cardiac Computed Tomography Angiography (CCTA)
  - The most important disadvantage of CCT (including CT angiography) as an imaging technique is the associated exposure to ionizing radiation.
- Cardiac catheterization
  - (hemodynamic and/or angiographic) in individuals with adult CHD AP classification II and III, or interventional cardiac catheterization in individuals with adult CHD AP classification I to III should be performed by, or in collaboration with, cardiologists with expertise in adult CHD.
- Exercise Testing
  - Exercise test does not imply stress imaging.
- Stress Imaging
  - includes MPI, stress echo, stress MRI
  - PET stress may be included as per **Cardiac PET (CD-6)**.
- Circumstances where CMR, CCT, TEE, and/or Cardiac Catheterization may be Superior to TTE
  - assessment of RV size and function in repaired Tetralogy of Fallot (TOF), systemic right ventricles, and other conditions associated with right ventricular (RV) volume and pressure overload
  - identification of anomalous pulmonary venous connections
  - serial assessment of thoracic aortic aneurysms, especially when the dilation might extend beyond the echocardiographic windows
  - accurate assessment of pulmonary artery (PA) pressure and pulmonary vascular resistance
  - assessment for re-coarctation of the aorta
  - sinus venosus defects
  - vascular rings
  - evaluation of coronary anomalies
  - quantification of valvular regurgitation

Modality	
Quantitative differential pulmonary perfusion and ventilation (e.g., aerosol or gas), including imaging when performed	78598

Congenital Heart Disease Imaging Indications

- The following sections are based on the congenital heart lesion. Requests for imaging based on other cardiac conditions, such as CAD, HCM, and acquired valvular lesions, should follow the adult cardiac guidelines for those conditions.

Aortopathies with CHD

- Dilated aortic arches are not uncommon with several congenital heart diseases and postoperative procedures including Aortic stenosis, Ross repair, Tetralogy of Fallot, Transposition of the great arteries (TGA), Pulmonary atresia, hypoplastic left heart syndrome (HLHS), Truncus Arteriosis, and single ventricle.

ASD-Atrial Septal Defects (CD-11.2.1)

CD.CHD.0011.2.1.A
v2.0.2026

Imaging at baseline and for cardiac clinical changes

- TTE
  - CMR, CCT (CPT® 75573), and/or TEE are medically necessary when TTE is suboptimal and either:
    - ASD is suspected
    - to evaluate pulmonary venous connections in known ASD
  - MRA Chest or CTA Chest are medically necessary when TTE shows pulmonary venous anomalies
    - If normal, repeat pulmonary vein imaging is not required.
- Diagnostic catheterization is medically necessary when there is either:
  - evidence of pulmonary hypertension
  - unanswered questions on CMR/CCT for venous drainage
- Stress imaging and coronary artery imaging is based on **Stress Testing with Imaging – Indications (CD-1.4)**.

Consideration of surgery

- Transesophageal echocardiogram (TEE) is recommended to guide percutaneous ASD closure.

Post-procedure imaging

- TTE is medically necessary post ASD device placement:
  - 1 week (if Amplatzer)
  - 1 month
  - 6 months (evaluate for erosion)
  - 12 months
  - then every 1-2 years
- Due to low-risk of erosion in PFO devices, PFO device closure requires follow-up at 6-12 months. No additional evaluation unless PFO not closed (see **Frequency of Echocardiography Testing (CD-2.3) PFO closure, TIPS, Cardiac device therapy, LVAD).**

Anomalous Pulmonary Venous Connections (CD-11.2.2)

CD.CHD.0011.2.2.A
v2.0.2026

Imaging at baseline and for cardiac clinical changes

- TTE
  - CMR and/or MRA Chest, or CT Cardiac and/or CTA Chest at time of diagnosis if any issues with pulmonary veins or RV volume
  - Cardiac catheterization at time of diagnosis for hemodynamic data and issues not answered on other imaging
- Routine stress imaging or coronary artery imaging not required
- Echocardiogram, CMR, CT, per cardiology request for clinical changes
  - Diagnostic heart catheterization if questions unanswered on imaging

Consideration of surgery

- Echocardiogram, CMR, CT, per cardiology request
- Diagnostic heart catheterization if unanswered questions on other imaging is needed for surgical management

Surveillance imaging anomalous pulmonary venous connections

Modality	Physiological stage / intervals for routine imaging (months)			
Physiological stage	**A**	**B**	**C**	**D**

Ventricular Septal Defect (VSD) (CD-11.2.3)

CD.CHD.0011.2.3.A
v2.0.2026

Imaging at baseline and for cardiac clinical changes

- TTE
  - CMR or CCT can be performed if questions are unanswered on echocardiogram
  - Catheterization at time of diagnosis for hemodynamics if pulmonary hypertension (PH) or shunt size is a question

Consideration of surgery

- TTE
  - CMR or CCT can be performed if questions are unanswered on echocardiogram.
  - Catheterization at time of diagnosis for hemodynamics if pulmonary hypertension (PH) or shunt size is a question

Surveillance imaging VSD

Modality	Physiological stage / intervals for routine imaging (months)

Atrioventricular Septal Defect (AV Canal, AVSD, Endocardial Cushion Defect) (CD-11.2.4)

CD.CHD.0011.2.4.A
v2.0.2026

Imaging at baseline and for cardiac clinical changes

- TTE
  - CMR or CT Cardiac at time of diagnosis if there are unanswered questions on echocardiogram
  - Cardiac catheterization at time of diagnosis when CMR and TTE leave questions unanswered that affect individual management
- Stress imaging per **Stress Testing with Imaging – Indications (CD-1.4)**

Consideration of surgery

- TTE
  - CMR or CT Cardiac if there are unanswered questions on TTE and information is needed for surgical management
  - Cardiac catheterization if CMR and TTE leave questions unanswered that affect surgical management

Surveillance imaging AVSD

Modality	Physiological stage / intervals for routine imaging (months)

Patent Ductus Arteriosus (PDA) (CD-11.2.5)

CD.CHD.0011.2.5.A
v2.0.2026

Imaging at baseline and for cardiac clinical changes

- TTE
  - MRI or MRA Chest or CT or CTA Chest if there are questions left unanswered by echocardiogram
  - Cardiac catheterization for hemodynamics (if planned device closure, diagnostic cardiac catheterization is not medically necessary as it is included in the procedure code)
- Stress imaging per **Stress Testing with Imaging – Indications (CD-1.4)**

Consideration of surgery

- TTE
- MRI or MRA Chest or CT or CTA Chest if there are unanswered questions on echo and information is needed for surgical management

Surveillance imaging PDA

Modality	Physiological stage / intervals for routine imaging (months)			
Physiological stage	**A**	**B**	**C**	**D**
Echo (TTE)	36	24	12	12

Subaortic Stenosis (SAS) (CD-11.2.8)

CD.CHD.0011.2.8.A
v2.0.2026

This section relates to subaortic stenosis caused by a discrete membrane or tunnel-like obstruction.

Imaging at baseline and for cardiac clinical changes

- Echocardiogram (TTE) (CPT® 93303 or 93304 or 93306 or 93308)
- Stress echo (CPT® 93350 or 93351) or SPECT MPI (CPT® 78452) or Stress MRI (CPT® 75559 or 75563)
  - once at the time of diagnosis
  - new or changed signs or symptoms of ischemia
  - changes in cardiac function
  - any signs or symptoms allowed in **Stress Testing with Imaging – Indications (CD-1.4)**

Consideration of surgery

- Echocardiogram (TTE) (CPT® 93303 or 93304 or 93306 or 93308)
- Stress echo (CPT® 93350 or 93351) or SPECT MPI (CPT® 78452) or Stress MRI (CPT® 75559 or 75563)

Surveillance imaging SAS

Modality	Physiological stage / intervals for routine imaging (months)

Congenital Valvular Aortic Stenosis (CD-11.2.9)

CD.CHD.0011.2.9.A
v2.0.2026

Imaging at baseline and for cardiac clinical changes

- TTE
- TEE is medically necessary when TTE is limited or equivocal.
- MRA Chest or CTA Chest if one of the following:
  - suspicion of Coarctation based on exam and echocardiogram
  - proximal ascending aorta not well visualized on TTE

Consideration of surgery

- TTE
- TEE is medically necessary when TTE is limited or equivocal.

Surveillance imaging congenital valvular aortic stenosis

Modality	Physiological stage / intervals for routine imaging			
Stage (valvular AS)	**Progressive (stage B) Mild Vmax 2.0-2.9 m/s**	**Progressive (stage B) Moderate Vmax 3.0-3.9 m/s**	**Severe (stage C) ≥4.0 m/s**	**Aortic root dilation >4.5 cm**
TTE	3 years	1 years	6 months	12 months
MRA Chest or CTA				if ascending allowed yearly

Degree of aortic stenosis (AS) severity			
	Mild AS	**Moderate AS**	**Severe AS**
Vmax (m/s)[a] maximum Doppler velocity	2.0-2.9	3.0-3.9	≥4.0

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Degree of aortic stenosis (AS) severity			
	Mild AS	**Moderate AS**	**Severe AS**
Mean gradient (mmHg)[a]	<30	30-49	≥50
AVA (cm^2) aortic valve area	>1.5	1.0-1.5	<1.0
AVAi (cm^2/m^2 BSA) indexed aortic valve area	≥1.0	0.6-0.9	<0.6
[a]At normal transvalvular flow, BSA= body surface area

Aortic Disease in Turner Syndrome (CD-11.2.10)

CD.CHD.0011.2.10.A
v2.0.2026

Dissection more common for a given aortic diameter. Mid-ascending aortic disease more common and my not be reliably seen on echocardiogram

Imaging at baseline and for cardiac clinical changes

- TTE
- MRA Chest or CTA Chest to rule out mid ascending aortic aneurysm if mid aorta was not seen on echocardiogram

Consideration of surgery

- TTE
- MRA Chest or CTA Chest if mid aorta was not seen on echocardiogram

Surveillance imaging aortic disease in Turner Syndrome

- Echocardiogram (TTE) yearly
  - MRA Chest or CTA if mid ascending aorta not visualized
- For documented thoracic aortic aneurysm (TAA) ≤4cm
  - Routine MRA Chest or CTA yearly
- For documented thoracic aortic aneurysm (TAA) >4cm
  - MRA Chest or CTA every 6 months.

Supravalvular Aortic Stenosis (CD-11.3.1)

CD.CHD.0011.3.1.A
v2.0.2026

Supravalvular aortic stenosis is a relatively rare condition overall but is seen commonly in individuals with Williams syndrome or homozygous familial hypercholesterolemia.

Imaging at baseline and for cardiac clinical changes

- TTE
- MRA Chest or CTA Chest
- Cardiac MRI or CTA Cardiac to assess coronary ostia
- New cardiac symptoms-any of the following:
  - CT Cardiac or cardiac MR
  - CTA Chest or MRA Chest
  - Stress imaging as per **Stress Testing with Imaging – Indications (CD-1.4)**

Consideration of surgery

- Cardiac catheterization for any individuals pre-cardiac intervention for coronary arteries

Surveillance imaging- Supravalvular AS

Modality	Physiological stage / intervals for routine imaging (months)			
Physiological stage	**A**	**B**	**C**	**D**
TTE	24	24	12	12

Coarctation of the Aorta (CD-11.3.2)

CD.CHD.0011.3.2.A
v2.0.2026

Coarctation is suspected based on clinical findings:
- BP higher in upper extremities than in the lower extremities
- absent femoral pulses
- continuous murmur
- abdominal bruit
- berry aneurysm with hemorrhage
- rib notching on x-ray
- abnormal thoracic aortic imaging and blood pressures

Imaging at baseline and for cardiac clinical changes
- TTE
  - No further imaging is required if echocardiogram (TTE), blood pressure, and exam rule out Coarctation.
  - If echocardiogram and exam are equivocal or positive, one of the following is medically necessary:
    - CTA Chest
    - MRA Chest
  - Individuals with Coarctation of the aorta do not require intra-cardiac MRI unless issue cannot be resolved on echocardiogram.
  - Screening for intracranial aneurysm by MRA (CPT® 70544, 70545, 70546) or CTA (CTP® 70496) of head is medically necessary.
- ETT for diagnosis of exercise-induced hypertension does not require imaging.
- Cardiac MRI not required unless issues unresolved by echo for intracardiac anatomy.
- Diagnostic catheterization is medically necessary prior to stenting of the coarctation.
- Stress imaging, TEE, Cardiac MRI or CT, Coronary imaging are not routine.

Symptomatic
- Individuals with Coarctation are at risk for dissection. When individual has new or worsening symptoms any of the following:
  - echocardiogram (TTE)
  - MRA Chest or CTA
- For exertional symptoms, one of the following:
  - Stress imaging per **Stress Testing with Imaging – Indications (CD-1.4)**
  - Cardiac MRI or CT Cardiac

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Consideration of surgery

- TTE
- MRA Chest or CTA Chest if TTE is equivocal or positive
- Diagnostic catheterization is medically necessary prior to stenting of the coarctation.

Surveillance imaging Coarctation of the Aorta

Modality	Physiological stage / intervals for routine imaging (months)

Valvular Pulmonary Stenosis (CD-11.3.3)

CD.CHD.0011.3.3.A
v2.0.2026

Imaging at baseline and for cardiac clinical changes

- TTE
- For issues affecting management not well visualized on TTE
  - Cardiac MRI or CT Cardiac
  - MRA Chest or CTA Chest

Consideration of surgery

- TTE
- Cardiac MRI or CT Cardiac and/or MRA Chest or CTA Chest for issues affecting surgical management not well visualized on TTE

Valvular PS imaging and testing

- Echocardiogram-stages
  - Mild PS-peak gradient <36 mmHg (peak velocity <3m/s)
  - Moderate PS-peak gradient 36-64 mmHg (peak velocity 3-4 m/s)
  - Severe PS-peak gradient >64 mmHg (peak velocity >4m/s); or mean gradient >35mmHg.
- Routine stress imaging is not required.
- Routine chest or cardiac or ischemia workup not required.

Surveillance imaging Valvular PS

Modality	Physiological stage / intervals for routine imaging (months)

Branch and Peripheral pulmonary stenosis (CD-11.3.4)

CD.CHD.0011.3.4.A
v2.0.2026

Overview
- Can be seen in newborns as a normal variant in the first 6 months of life
- Can be seen in surgeries of right ventricular outflow (TOF)
  - Noonan
  - Alagille
  - Williams
  - Maternal rubella exposure
  - Keutel syndrome

Imaging at baseline and for cardiac clinical changes
- TTE
- MRA Chest or CTA Chest
- Cardiac CT or Cardiac MR
- Catheterization may be considered if other advanced imaging is not adequate for management.
- VQ scan or MRA Chest for differential blood flow

Consideration of surgery
- TTE
- MRA Chest or CTA Chest
- Cardiac CT or Cardiac MR
- Catheterization is medically necessary when other advanced imaging does not provide necessary information for surgical management.

Surveillance imaging branch and peripheral pulmonary stenosis

Tetralogy of Fallot (TOF, VSD with PS) (CD-11.3.7)

CD.CHD.0011.3.7.A
v2.0.2026

Includes TOF with pulmonary atresia, VSD PA

Imaging at baseline and for cardiac clinical changes

Baseline

- TTE
- Cardiac MR or CCT/CCTA Cardiac
- MRA Chest or CTA Chest
- Cardiac catheterization if other advanced imaging leaves unanswered questions

New or worsening symptoms

- Repeat baseline advanced imaging
  - new or worsening symptoms
  - new EKG changes
- Stress imaging (stress echo, stress MRI, or MPI) allowed for typical chest pain, even if intermediate pretest probability at atypical symptoms in individuals with known or undefined coronary artery (CA) anatomy or CA pathology
- VQ scan or MRA chest for left/right perfusion abnormality

Prior to cardiac intervention or surgery

- Repeat baseline imaging (TTE/MR/CT)
- Catheterization prior to surgery or intervention
  - If planned Catheter Pulmonary Valve replacement, procedure includes diagnostic catheterization and hemodynamics, and diagnostic catheterization is not billed separately.

Surveillance imaging Tetralogy of Fallot (TOF)

Right Ventricle-to-Pulmonary Artery Conduit (CD-11.3.8)

CD.CHD.0011.3.8.A
v2.0.2026

Imaging at baseline and for cardiac clinical changes

- TTE
- Cardiac MRI or CCT/CCTA Cardiac
- MRA Chest or CTA Chest
- Catheterization allowed for new symptoms or with new imaging findings as needed for management
- Stress imaging (stress echo, stress MRI or MPI) as requested for cardiac symptoms

Consideration of surgery- Surgical repair for many lesions such as TOF/ Truncus / Pulmonary atresia

- TTE
- Cardiac MRI or CCT/CCTA Cardiac
- MRA Chest or CTA Chest

Surveillance imaging Right Ventricle-to-Pulmonary Artery Conduit

Modality	Physiological stage / intervals for routine imaging (months)			
Physiological stage	**A**	**B**	**C**	**D**
TTE	12	12	12	12

Transposition of the Great Arteries (TGA) (CD-11.3.9)

CD.CHD.0011.3.9.A
v2.0.2026

Imaging at baseline and for cardiac clinical changes

- TTE
- Cardiac MRI or CCT/CCTA
- MRA Chest or CTA

In addition to repeat imaging with the above baseline studies, the following studies are medically necessary as follows:

- stress imaging as requested for symptoms or signs of ischemia
- V/Q scan for left to right PA perfusion or MRA Chest
- Symptomatic individuals should be offered stress physiological imaging and repeat anatomic imaging considered if symptoms are suggestive of coronary ischemia (regardless of Diamond Forester pretest probability category).
- catheterization right and left heart when above advanced imaging does not explain clinical issues

Consideration of surgery

- TTE
- Cardiac MRI or CCT/CCTA
- MRA Chest or CTA

Surveillance imaging TGA

Modality	Physiological stage / intervals for routine imaging (months)

Fontan Palliation of Single Ventricle Physiology (CD-11.3.11)

CD.CHD.0011.3.11.A
v2.0.2026

Including Tricuspid Atresia and Double Inlet Left Ventricle, HLHS, HRHS, PA, Mitral atresia, AVC unbalanced, single ventricle, DIRV, pulmonary atresia, HLHS, Glen procedure, TA, double outlet right ventricle (DORV), and single ventricle physiology

Imaging at baseline and for cardiac clinical changes

- TTE
- CMR or CCT/CCTA for issues that are equivocal on TTE (can be done annually versus based on below chart for individuals who have prior issues that were equivocal on echo, and the data is required for management)
- Cardiac catheterization prior to surgical interventions
- Echocardiogram/CMR/CCT or CCTA/MRA Chest or CTA Chest/catheterization with any new signs or symptoms
- V/Q scan or MRA for lung perfusion left vs. right

Consideration of surgery

- Cardiac catheterization prior to surgical interventions

Surveillance imaging Fontan Palliation of Single Ventricle Physiology

Modality	Physiological stage / intervals for routine imaging (months)			
Physiological stage	**A**	**B**	**C**	**D**

Severe Pulmonary Hypertension (PH) and Eisenmenger Syndrome (CD-11.3.12)

CD.CHD.0011.3.12.A
v2.0.2026

Imaging at baseline or for cardiac clinical changes

- TTE
  - initial diagnosis
  - with new signs or symptoms
- CMR/CCT or CCTA or CTA/MRA Chest or Cardiac catheterization
  - echocardiogram (TTE) results suggest PH
  - new signs or symptoms with PH

Consideration of surgery or for treatment planning

- TTE
- Cardiac catheterization if TTE suggests PH
- CMR/CCT or CCTA or CTA/MRA Chest if additional information is needed for treatment planning

Surveillance imaging Severe Pulmonary artery hypertension (PH) and Eisenmenger syndrome

Modality	Physiological stage / intervals for routine imaging (months)			
Physiological stage	**A**	**B**	**C**	**D**
TTE			6	6
CMR or CCT/ CCTA			As needed	As needed

Coronary Artery Anomalies (CD-11.3.13)

CD.CHD.0011.3.13.A
v2.0.2026

Imaging at baseline and for cardiac clinical changes

- TTE
  - at baseline
  - any signs or symptoms
- CCT/CCTA or CMR or catheterization for initial evaluation
- Coronary artery from wrong sinus-baseline stress imaging regardless of symptoms
- Stress imaging for any cardiac signs or symptoms
- For Kawasaki guideline regarding echo, Stress imaging, coronary imaging, see pediatric guideline **Kawasaki Disease (PEDCD-6)**.

Consideration of surgery

- TTE
- CCT/CCTA or CMR or catheterization

Evidence Discussion (CD-11)

Adult Congenital Heart Disease Imaging

- Management of Adult Congenital heart (ACHD) disease involves a multimodal imaging approach. Multimodal imaging helps account for patient-specific considerations, strengths and weaknesses of each modality, institutional resources, and available expertise. Approaches to limit and monitor radiation exposure are recommended during imaging of individuals with ACHD, and studies that do not involve ionization radiation should be prioritized whenever appropriate.
- Echocardiogram, MRI, CT, catheterization, and nuclear stress testing all have strengths and weaknesses, including varying radiation levels, temporal resolution, spatial resolution, and ability to image blood flow. Advantages of the various modalities are as follows: MRI has the ability to image the right ventricle in 3D; Echocardiograms include high temporal resolution and availability, and the ability to measure pressures with catheterizations; Cardiac CTs have the ability to rapidly acquire 3D imaging; and nuclear imaging allows the ability to measure myocardial perfusion concerns.

Diagnostic Cardiovascular Imaging Pre-Pregnancy to Post-Partum (CD-15.1)

CD.MI.0015.1.A
v2.0.2026

Peripartum Red Flag Signs and Symptoms

Imaging as requested, as listed within **Imaging Modalities in Maternal Imaging** (Echocardiogram, Exercise stress echo, Coronary angiography, Cardiac MRI), is medically necessary for peripartum individuals for any of the following **red flag** signs or symptoms:

- chest pain
- dyspnea
- orthopnea
- cough
- lower extremity edema when there is a concern for heart disease
- tachycardia
- unheralded syncope
- headache
- acute visual changes
- new onset hypotension
- hypertension

Imaging Modalities

General information

Ultrasound and magnetic resonance are the preferred imaging modalities to minimize radiation exposure in pregnancy. When imaging using ionizing radiation is necessary, radiation exposure should follow the ALARA principle (As Low As Reasonably Achievable). Shared decision-making regarding diagnostic testing should occur in consultation with the individual, cardiologist, and obstetrical team when weighing the risk of fetal exposure to radiation against the need to diagnose or plan treatment for serious illness.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Transthoracic echocardiography (TTE)

- TTE (CPT® 93306) is the primary cardiac imaging modality in pregnancy. Baseline and surveillance echocardiography is medically necessary for several conditions as noted in **Maternal imaging in cardiovascular disease (CD-15.2)** Table 1.
- A repeat echocardiogram is medically necessary when there are new or worsening cardiovascular signs or symptoms, as described in **Peripartum Red Flags**, **Transthoracic Echocardiography (TTE)– Indications/initial evaluation (CD-2.2)** and **Frequency of Echocardiography Testing (CD-2.3)**, during and after pregnancy.

Exercise Stress Echo

- Exercise stress echo (CPT® 93350, 93351) is medically necessary pre-conception to assist with risk stratification in individuals with a documented history of **any** of the following:
  - current left ventricular dysfunction
  - previous history of left ventricular dysfunction
  - valvular heart disease of any severity
  - There is a concern for myocardial reserve.
- See Stress echocardiogram in **Stress Testing with Imaging – Indications (CD-1.4)** and **Stress echo–indications other than ruling out CAD (CD-2.7)**.
- See **Hypertrophic Cardiomyopathy (CD-14).**

Coronary Angiography

- Fetal risk from ionizing radiation is highest before 20 weeks gestational age. When coronary angiography is medically necessary, the ALARA principle should be followed. Invasive management of acute coronary syndrome is associated with lower in-hospital mortality and should be considered. See **Diagnostic Heart Catheterization**.

Cardiac MRI

- Cardiac MRI (CPT® 75557) is utilized in pregnant individuals to measure aortic dimensions, wall motion, and ventricular function when the echocardiogram is non-diagnostic. Gadolinium-based contrast agents are not necessary in aortic imaging or most other indications in pregnancy. See **Cardiac MRI**.

Evidence Discussion

- Cardiovascular disease (CVD) in pregnancy has become increasingly prevalent in recent years.
- The increase in plasma volume during pregnancy requires significant physiological adaptation.
- Maternal mortality has increased in the last two decades with CVD accounting for 33% of all deaths.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Invasive management of myocardial infarction (MI) is associated with lower in-hospital mortality.
- Research has underrepresented females of childbearing age leading to significant deficits in our knowledge of cardiovascular care of these individuals.
- Cardiac Imaging using ionizing radiation
  - Multiple imaging modalities expose the pregnant individual and fetus to ionizing radiation.
  - This exposure causes concern for an elevated risk of childhood cancer.
  - Shared decision-making should be employed when weighing the fetal exposure to radiation against the need to diagnose serious illness.

Maternal Imaging in Cardiovascular Disease (CD-15.2)

CD.MI.0015.2.A
v2.0.2026

Table 1: Suggested frequency of echo monitoring during pregnancy

Cardiovascular disease	Monitoring frequency
Hypertensive disorders of pregnancy (BP ≥130/90)	• An echocardiogram (TTE) (CPT® 93303, 93304, 93306, 93307, 93308) is medically necessary once during pregnancy in all hypertensive disorders of pregnancy. • A repeat TTE is medically necessary when there are new or worsening cardiovascular signs or symptoms.
Valvular disorders/ Native and Prosthetic	• 1 TTE is medically necessary during the first trimester (weeks 1-12 of pregnancy) for individuals with known or suspected valvular heart disease. • A repeat TTE is medically necessary when there are new or worsening cardiovascular signs or symptoms.
Severe Aortic stenosis (AS)	• A repeat TTE is medically necessary every 1-2 months or when there are new or worsening cardiovascular signs or symptoms.
Mitral stenosis (MS)	• TTE is medically necessary each trimester (12 weeks) and prior to delivery in individuals with mild MS. • TTE is medically necessary every 1–2 months in individuals with moderate to severe MS. • A repeat TTE is medically necessary when there are new or worsening cardiovascular signs or symptoms.
Dilated cardiomyopathy	• TTE is medically necessary during each trimester (12 weeks). • A repeat TTE is medically necessary when there are new or worsening cardiovascular signs or symptoms.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Cardiovascular disease	Monitoring frequency
Hypertrophic cardiomyopathy	• TTE is medically necessary in **asymptomatic** individuals each trimester. • TTE is medically necessary in **symptomatic** individuals every 1-2 months. • A repeat TTE is medically necessary when there are new or worsening cardiovascular signs or symptoms.
Peripartum cardiomyopathy	• TTE is medically necessary in individuals with signs and symptoms of heart failure. • A repeat TTE is medically necessary when there are new or worsening cardiovascular signs or symptoms. ◦ TTE is medically necessary in subsequent pregnancies: ▪ at the time of the first prenatal visit ▪ at the end of the first and second trimesters ▪ 1 month prior to delivery ▪ after delivery prior to discharge ▪ 1 month postpartum ▪ at any time when there are worsening signs or symptoms of heart failure • TTE is medically necessary as requested when the individual is being treated with Cabergoline for peripartum cardiomyopathy.
Pulmonary hypertension	• TTE is medically necessary in individuals with signs and symptoms of pulmonary hypertension. • A repeat TTE is medically necessary at the discretion of the health care provider.

Maternal Imaging in Individuals with Aortopathy (CD-15.3)

CD.MI.0015.3.A
v2.0.2026

Pre-pregnancy imaging

Individuals at risk for aortic aneurysms **(Table 15-3-1)** should be evaluated with echocardiogram (TTE) **and** Computed Tomography (CT)/Magnetic Resonance Imaging (MRI) of the Chest/Abdomen/Pelvis **(Table 15-3-2)** within 1 year prior to conception to evaluate for aortic valve disease and aortic dimensions.

Table 15-3-1

Individuals at risk for aortic aneurysm, aortic dissection, limb-threatening ischemia
Bicuspid Aortic Valve
Turner Syndrome
Coarctation of the Aorta
Marfan Syndrome
Type IV Ehlers-Danlos
Loeys-Dietz
Familial Thoracic Aortic Disease and Aortic Dissection (defined as first-degree relative with history of aortic dissection or thoracic aortic aneurysm or two second-degree relatives with history of aortic dissection or thoracic aortic aneurysm)

Table 15-3-2

Imaging for Aortic conditions	CPT®
CT Chest and/or Abdomen and/or Pelvis	71260 74177 74160 72193

Proprietary Information of UnitedHealthcare.

Suggested Frequency of Aortic Imaging during pregnancy and postpartum in individuals known to be high-risk for aortic aneurysm

Table 15-3-3

Condition	WHO Class	Imaging frequency	Postpartum (up to 42 days after birth)
Turner Syndrome	• II-III: Aortic root <20mm/m^2 with associated risk factors or <25mm/m without associated risk factors	• Once during pregnancy if normal aortic dimension, or every 2 months if repaired coarctation	• Once during the postpartum period
	• IV: Aortic root ≥20mm/m2 with associated risk factors or ≥25mm/m without associated risk factors	• Every 6 weeks if aorta diameter dilated >30mm	• Once during the postpartum period
	• Any individual with Turner who has severe coarctation	• At discretion of provider	• Once during the postpartum period
Marfan Syndrome	• III: Aortic root <45mm, mod-severe Aortic Insufficiency	• Every trimester if <40mm	• Once during the postpartum period
	• IV: Aortic root ≥45mm, history of dissection	• Every 6 weeks if aorta is ≥40mm	• Once during the postpartum period
Vascular Ehlers-Danlos	• Type IV	• Every 6 weeks	• Once during the postpartum period
Loeys-Dietz	• III: Aortic diameter <40mm	• Every 6 weeks	• Once during the postpartum period
	• IV: Aortic diameter ≥40mm	• Every 6 weeks	• Once during the postpartum period

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Condition	WHO Class	Imaging frequency	Postpartum (up to 42 days after birth)
Familial thoracic aortic aneurysms and dissections	• III: Aortic diameter <40mm	• Every trimester if <40mm aortic diameter	• Once during the postpartum period
	• IV: Aortic diameter ≥40mm	• Every 6 weeks if ≥40mm aortic diameter	• Once during the postpartum period

Background and Supporting Information

Imaging in Pregnancy with Congenital Heart Disease (CHD) (CD-15.4)

CD.MI.0015.4.A
v2.0.2026

Pre-pregnancy imaging based on the World Health Organization (WHO) chart for imaging in pregnancy with CHD

Imaging modality and indication	CPT®
Echocardiogram (TTE) when planning pregnancy	93306
TEE if TTE equivocal	93312
CMR (cardiac MRI) can be performed prior to pregnancy in those lesions where CMR would be routinely performed at some later date	75557
CTA or MRA of chest if known aortic disease, Pulmonary artery disease, anomalous pulmonary veins, anomalous systemic veins (also see peripartum aortopathy table)	71275, 71555
Echocardiogram with new signs or symptoms	93303, 93304, 93306, 93308
Postpartum imaging per provider requested frequency	imaging as noted above
Stress imaging pre/during pregnancy when known coronary artery anomaly, pulmonary hypertension, LVOT obstruction, cardiac dysfunction, single ventricle	93350, 93351, 93320, 93325
WHO II, III, IV, can have echo/MR/CT/stress imaging prior to pregnancy	imaging as noted above

- Congenital heart disease imaging in pregnancy
  - Echocardiogram (TTE) when planning pregnancy
  - TEE if TTE equivocal
  - CMR can be performed prior to planning pregnancy in those lesions where CMR would be routinely performed at some later date.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- CTA Chest or MRA Chest of arch if known disease with aortic involvement or if known dilation
- Repeat echocardiogram and MR (can be without gad) can be performed based on the WHO classification II, III, IV, or other risk factors.
- Severe complex CHD TTE (CPT® 93306)
  - Every 2-4 weeks for major physiological changes
  - As often as needed for any of the following:
    - pulmonary hypertension
    - changes in function
    - to guide delivery after 24 weeks
- Echocardiogram can be performed if there are new signs or symptoms during pregnancy.
- Postpartum first year can have more frequent imaging.
- Stress imaging pre/during pregnancy for individuals with known coronary artery anomaly, pulmonary hypertension, LVOT obstruction, cardiac dysfunction, single ventricle.
- WHO II, III, IV can have echocardiogram/MR/CT/stress imaging prior to pregnancy
- WHO I-one echocardiogram during pregnancy
- WHO II-one echocardiogram per trimester during pregnancy
- WHO II/III-echocardiogram every 2 months during pregnancy
- WHO III/IV-echocardiogram monthly during pregnancy
  - Individuals may require more (even weekly) if treatment decision, delivery is considered.

- Syndromes that allow cardiac imaging at the time of diagnosis if not previously done. This list is not exhaustive.
  - DiGeorge/velocardiofacial (22q11.2)
  - Down syndrome (trisomy 21)
  - Holt Oram (TBX5)
  - Klinefelter syndrome (47 XXY)
  - Noonan (PTPN11, KRAS, SOS1 RAF1, NRAS, BRAF, MAP2K1)
  - Turner (45X)
  - Williams (7q11.23 deletion)
  - any syndrome associated with congenital heart disease
- Echocardiogram at time of diagnosis (either genetic testing or clinical features)
- CMR or CCTA if arch involved in disease.

Surveillance Imaging

Surveillance imaging after baseline studies

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

After initial imaging, TTE should be performed at regular intervals. For individuals with aortopathy, Chest MRA may be added at the same frequency. If echocardiographic imaging is known to be poor or inadequate, CMR may be used instead of TTE.

The World Health Organization modified classification of maternal cardiovascular risk

The World Health Organization established a modified classification of maternal cardiovascular risk used as a tool to evaluate risk status for pregnant individuals with various cardiovascular conditions.

Class	Risk	Sample Lesions
WHO Class I	No detectable increased risk of maternal mortality and no or mild increase in morbidity.	• Mild Pulmonary stenosis • Small PDA • Mild MVP • Successfully repaired simple lesions (ASD, VSD, PDA, anomalous pulmonary venous drainage) • Isolated PACs or PVCs
WHO Class II	Small increased risk of maternal mortality or moderate increase in morbidity.	• Un-operated ASD or VSD • Repaired TOF (uncomplicated) • Most arrhythmias
WHO Class II-III	Intermediate increased risk of maternal mortality or moderate to severe increase in morbidity.	• Mild left ventricular impairment • Hypertrophic cardiomyopathy • Native or tissue valvular heart disease not considered WHO I or IV • Aorta <45 mm in aortic disease associated with bicuspid aortic valve • Repaired coarctation

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Class	Risk	Sample Lesions
WHO Class III	Significantly increased risk of maternal mortality or severe morbidity. • Expert counseling required. • If pregnancy is decided upon, intensive specialist cardiac and obstetric monitoring needed throughout pregnancy, childbirth, and the postpartum period.	• Mechanical valve • Systemic right ventricle • Fontan circulation • Unrepaired cyanotic heart disease • Other complex congenital heart disease
WHO Class IV	Extremely high-risk of maternal mortality or severe morbidity. • Pregnancy contraindicated. • If pregnancy occurs, termination should be discussed. • If pregnancy continues, care for as WHO class III.	• Pulmonary arterial hypertension from any cause • Severe systemic ventricular dysfunction (LVEF <30%, NYHA functional class III-IV) • Severe mitral stenosis; severe symptomatic aortic stenosis • Aortic dilation ≥50mm in aortic disease associated with bicuspid aortic valve • Native severe coarctation of the aorta

Cardiotoxic Agent-Related Cardiac Dysfunction (CD-12)

CD.CS.0012.A
v2.0.2026

Cardiotoxic Agent/Cancer Therapeutics-Related Cardiac Dysfunction (CD-12.1)

Transthoracic Echocardiogram (TTE)

Transthoracic Echocardiogram (TTE) is medically necessary to determine Left Ventricular (LV) function in individuals on cardiotoxic chemotherapeutic drugs.

- 3D echocardiography (CPT® 93319) is medically necessary in addition to the primary TTE and is the preferred echocardiography modality for the assessment of left ventricular ejection fraction (LVEF) and cardiac volumes. See **3D Echocardiography (CD 2.9)**.
- Myocardial strain imaging (CPT® 93356) to obtain a Global Longitudinal Strain (GLS) is medically necessary as an important adjunct in screening for CTRCD. See **Myocardial Strain Imaging (CD 12.2).**

Multimodality imaging

- Guidelines support using echocardiography rather than MUGA for the determination of LVEF and/or wall motion EXCEPT in one of the circumstances described previously in **MUGA Study – Cardiac Indications (CD-3.4)** (see **Background and supporting Information** below).
- CT calcium scoring is considered medically necessary to evaluate for radiation induced CAD when all of the following conditions exist:
  - The individual has no symptoms suspicious for ischemia such as chest discomfort located retrosternally, epigastric, or referred pain (pain that is felt in a place different than the source) in the neck, shoulder, arm, or jaw described as pain, pressure, constricting, or tightness occurring with exertion or emotional stress and relieved by rest, nitroglycerin, or both.
  - The individual has no clinical history or prior cardiac imaging documenting CAD.
  - There has been no prior calcium score >0.
  - There has been ≥5 years since the last RT (radiotherapy/radiation) treatment for the initial study or at least 5 years since the last CT calcium scoring for subsequent testing.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Cardiac MRI (CMR) is medically necessary in the evaluation of CTRCD for the following:
  - TTE is not diagnostic
  - Tissue characterization for cardiomyopathy or myocarditis, particularly when Immune Checkpoint Inhibitor Myocarditis is being questioned
  - See also **Cardiac MRI and MRA Chest – Indications (CD 5.2)**.

Frequency of CTRCD screening

- Baseline
  - All individuals can have a baseline TTE prior to initiation of cardiotoxic agents.
- During treatment with cardiotoxic agents
  - The frequency of monitoring depends on the agent administered and the individual's baseline cardiovascular toxicity risk. (see **Background and Supporting Information** below)
- Post treatment with cardiotoxic agents surveillance
  - One TTE is medically necessary 3 to 12 months after completion of therapy.
- Adult cancer survivors
  - Long term surveillance TTE is medically necessary every 5 years, except in those with low risk.
  - Additional surveillance TTE at 1 and 3 years after cancer therapy completion is medically necessary in those deemed to be high risk for CTRCD.
- Adult survivors of childhood and adolescent cancer
  - Surveillance TTE is medically necessary every 2 years for survivors with indeterminate risk due to unknown cancer therapy history.
  - Surveillance TTE is medically necessary every 2 years for high risk survivors, defined as a history of any of the following:
    - Radiation dose ≥30 Gy
    - Anthracycline dose of ≥100 mg/m^2 and radiation dose ≥15 Gy
    - Anthracycline dose ≥250 mg/m^2
  - Surveillance TTE is medically necessary every 5 years for moderate risk survivors, defined as a history of any of the following:
    - Radiation dose ≥15 to <30 Gy
    - Anthracycline dose of < 250 mg/m^2 and radiation dose <15 Gy
  - No screening is medically necessary in low risk survivors, defined as a history of any of the following:
    - Anthracycline dose of >0 to <100 mg/m^2
    - Radiation dose >0 to <15 Gy

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- TTE is medically necessary for cancer survivors with a history of chest radiotherapy or anthracycline exposure who are pregnant or planning to become pregnant as follows:
  - Baseline exam
  - 12 weeks of pregnancy if missed the baseline TTE or in high risk survivors
  - 20 weeks of pregnancy for high risk survivors
  - TTE can be repeated for any cardiac symptoms at any other time as needed during or immediately following pregnancy
- For adults who received anthracyclines in childhood, see **Cardiotoxicity and Echocardiography (PEDONC-19.2).**

Background and Supporting Information

- High value screening protocol to detect CTRCD using TTE (CPT® 93306 or 93308) is contingent upon careful baseline cardiotoxicity risk assessment and stratification into low, moderate, and high risk. Currently, there is no universally accepted risk score. Documentation of risk by the provider is sufficient to guide screening strategy.
- Advantages of Echocardiography in comparison to MUGA in individuals on cardiotoxic chemotherapy:
  - no ionizing radiation
  - no IV access required when echo contrast is not used
  - allows view of the pericardium to look for effusion
  - allows estimate of pulmonary pressure
  - may allow visualization of a clot or tumor in the Inferior Vena Cava (IVC) and/or the right heart

Myocardial Strain Imaging (CD-12.2)

- Myocardial strain imaging (CPT® 93356) in addition to the primary echocardiogram in individuals receiving therapy with cardiotoxic agents for **any** of the following:
  - Initial evaluation-prior to treatment with **either**:
    - medications that could result in cardiotoxicity/heart failure
    - radiation that could result in cardiotoxicity/heart failure
  - re-evaluation of an individual previously or currently undergoing therapy as per echocardiogram parameters (see **Cardiotoxic agent/Cancer Therapeutics-Related Cardiac Dysfunction (CD-12.1))**
  - re-evaluation of an individual undergoing therapy with worsening symptoms

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Mavacamten for Obstructive Hypertrophic Cardiomyopathy (HCM) (CD-12.3)

Echocardiogram (CPT® 93306) is medically necessary for individuals treated with mavacamten for class II-III obstructive HCM as follows:

Initiation of treatment

- Baseline-at the beginning of treatment
- 4 weeks after treatment initiation
- 8 weeks after treatment initiation
- 12 weeks after treatment initiation
- Then every 12 weeks while on mavacamten

Changes in treatment

- 4 weeks after any interruption of treatment (any missed dose)
- After any dosage change (including restart of treatment):
  - 4 weeks after dosage change
  - 12 weeks after dosage change
- After initiating a weak CYP2C19 inhibitor (e.g., omeprazole) or moderate CYP3A4 inhibitor (e.g., ciprofloxacin):
  - 4 weeks after start of medication
  - 12 weeks after start of medication
- At any time regardless of timing of prior echo when there are new cardiac signs or symptoms, or worsening of clinical status

See also **Hypertrophic Cardiomyopathy (HCM) (CD-14)**

Background and Supporting Information

Hypertrophic Cardiomyopathy (HCM) is a clinical diagnosis, established by imaging with 2D echocardiography or cardiovascular magnetic resonance (CMR) showing a maximal end-diastolic wall thickness of ≥15 mm anywhere in the left ventricle, in the absence of another cause of hypertrophy in adults. More limited hypertrophy (13-14 mm) can be diagnostic, particularly when present in family members of an individual with HCM or in conjunction with a positive genetic test, and/or associated with typical dynamic outflow obstruction, or distinctly abnormal ECG patterns.

Click Here to Return to the Main TOC

Cardiac Sarcoidosis (CD-3.9)

CD.CS.0003.9.A
v2.0.2026

Imaging indications

Suspected cardiac sarcoidosis

- Cardiac MRI with gadolinium (CPT® 75561) is medically necessary initial imaging for identification of suspected cardiac sarcoidosis.
- Cardiac PET (CPT® 78432 or 78433) **or** PET metabolic study (CPT® 78459 or 78429) and SPECT perfusion image (CPT® 78451) is medically necessary for suspected cardiac sarcoidosis for any of the following indications:
  - initial imaging when there is a contraindication to MRI imaging (non MRI-safe pacemaker, renal failure)
  - initial Cardiac MRI is equivocal or additional information is needed based on results from the MRI
  - to confirm diagnosis if suggested by MRI
  - initial imaging to evaluate for suspected cardiac sarcoidosis when there is documented sarcoidosis outside of the heart

Monitoring of treatment of established cardiac sarcoidosis

- PET-Cardiac PET metabolic is medically necessary to monitor therapy in cardiac sarcoidosis. Requires PET with F-18 FDG metabolic study combined with a PET perfusion study (CPT® 78432 or 78433) OR PET metabolic study (CPT® 78459 or 78429) and SPECT perfusion image (CPT® 78451).
  - prior to treatment of cardiac sarcoidosis
  - PET (heart FDG metabolic with perfusion study as above) can be repeated at 3-6 month intervals if there is active disease or to make therapeutic decisions.

Evidence Discussion

- Cardiac imaging is reasonable to detect cardiac sarcoidosis in the following:
  - any individual with extra cardiac sarcoidosis even if no cardiac symptoms
  - echo with basal thinning of the intraventricular septum, depressed EF <50 or regional wall motion abnormality not associated with CAD
  - young individuals with unexplained ventricular tachycardia, especially monomorphic VT

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - individuals with unexplained cardiomyopathy or heart failure (i.e., CAD has been ruled out)
  - individuals with unexplained arrhythmia especially advanced AV block or VT
- Initial imaging should be cardiac MRI with late gadolinium enhancement (LGE) protocol unless there is a contraindication to MRI imaging (non MRI-safe pacemaker, renal failure). Absence of LGE is a strong negative predictor for low rates of cardiac morbidity and mortality from cardiac sarcoidosis and further testing is not usually medically necessary.
- PET – Metabolic imaging with F-18 FDG for diagnosis if there is a contraindication to MRI and cardiac sarcoidosis is suspected. This requires PET with F-18 FDG metabolic study combined with a PET perfusion study.
- Full body PET/CT (CPT® 78815) is not medically necessary for the diagnosis or monitoring response to therapy of cardiac sarcoidosis. It may be considered to assist in diagnosis and/or treatment options in some instances of pulmonary sarcoidosis. See **Sarcoid (CH-15.1)** in the Chest Imaging Guidelines.

Myocardial Tc-99m Pyrophosphate Imaging in Cardiac Amyloidosis (CD-3.8)

CD.NC.0003.7.A
v2.0.2026

Coding

Cardiac Pyrophosphate Scan	CPT®
Myocardial Imaging, infarct avid, planar, qualitative or quantitative	78466
Myocardial Imaging, infarct avid, planar, qualitative or quantitative with ejection fraction by first pass technique	78468
Myocardial Imaging, infarct avid, planar, qualitative or quantitative tomographic SPECT with or without quantification	78469
Radiopharmaceutical Localization Imaging Limited area	78800
Radiopharmaceutical Localization Imaging SPECT	78803
Radiopharmaceutical localization of tumor, inflammatory process or distribution of radiopharmaceutical agent(s) (includes vascular flow and blood pool imaging, when performed); tomographic (SPECT) with concurrently acquired computed tomography (CT) transmission scan for anatomical review, localization and determination/detection of pathology, single area (e.g., head, neck, chest, pelvis), single-day imaging	78830

- Historically this method of imaging the myocardium was used to identify recent infarction, hence, the term "infarct-avid scan." Although still available, the sensitivity and specificity for identifying infarcted myocardial tissue are variable and the current use for this indication is limited. See **Cardiac MRI (CD-5)**.
- Tc-99m pyrophosphate imaging (CPT® 78469, 78803, or 78830) is medically necessary to identify cardiac amyloidosis.
- Chest SPECT and planar imaging may be used, as well as whole-body imaging for identification of systemic ATTR (transthyretin) amyloidosis.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- For a single planar imaging session alone (without a SPECT study), report CPT® 78800 Radiopharmaceutical Localization Imaging Limited area
- Note: When reporting CPT 78803, planar imaging of a limited area or multiple areas should be included with the SPECT

Indications

Tc-99m pyrophosphate imaging (CPT® 78469, 78803, or 78830) is medically necessary for **any** of the following:

- For diagnosis of ATTR amyloidosis in an individual undergoing evaluation for kidney transplant when **both**:
  - There is known systemic amyloidosis.
  - Cardiac MRI (CMR) is either contraindicated or indeterminate. See **Kidney Transplant, Pre-Transplant Imaging Studies (AB-42.5)**.
- For diagnosis of ATTR amyloidosis after negative screening for presence of a monoclonal light chain to exclude AL amyloidosis :
  - Serum kappa/lambda free light chain ratio (not SPEP)
    - Abnormal if ratio is <0.26 or >1.65
  - Serum or urine immunofixation electrophoresis (IFE)
    - Abnormal if monoclonal protein detected
- Diagnosis of cardiac ATTR in an individual with cardiac MRI or echocardiography findings consistent with or suggestive of cardiac amyloidosis
- Diagnosis of cardiac ATTR in an individual with known systemic amyloidosis or ATTR gene positive
- Diagnosis of an individual with suspected cardiac ATTR amyloidosis when there is a contraindication to CMR such as renal insufficiency or an implantable cardiac device

---

Note:

Cardiac follow-up should be based on Echocardiogram, Tn, NT-proBNP, clinical exam and symptom

---

Background and Supporting Information

- The following conditions would raise high index of suspicion:
  - left ventricular hypertrophy but low voltage on ECG
  - heart failure with preserved ejection fraction and an increase in left ventricular wall thickness
  - unexplained heart failure with preserved ejection fraction and concomitant right heart failure in an individual over the age of 60

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- individuals, especially elderly males, with signs/symptoms of heart failure and any of the following:
  - lumbar spinal stenosis
  - spontaneous biceps tendon rupture
  - bilateral carpal tunnel syndrome
  - atrial arrhythmia in the absence of usual risk factors
- known or suspected familial amyloidosis
- low flow, low gradient aortic stenosis

Evidence Discussion

Appropriate Use Criteria from major professional societies including the American College of Cardiology and the American Heart Association support the use of myocardial perfusion imaging (MPI) with single photon emission computed tomography (SPECT) for individuals with signs or symptoms consistent with coronary artery disease (CAD) such as typical angina. In addition, they support the use of SPECT perfusion imaging in symptomatic individuals with known CAD and those with prior interventions such as coronary artery bypass surgery, coronary stenting, and preoperative risk stratification. These guidelines balance the appropriate testing of individuals with SPECT versus unnecessary and potentially harmful testing and downstream procedures.

Also, as supported by society guidelines, use of SPECT is medically necessary in detection of cardiac transthyretin amyloidosis (ATTR) after light chain amyloidosis (AL) is ruled out by appropriate blood and urine testing.

Click Here to Return to the Main TOC

Congestive Heart Failure (CD-9)

CD.CS.0009.A
v2.0.2026

CHF – Imaging (CD-9.1)

- Congestive heart failure (CHF), including post-cardiac transplant failure:
  - Echocardiogram is the first study after the clinical evaluation for suspected CHF.
  - MUGA, cardiac MRI, or cardiac CT may be medically necessary if the ECHO is limited or does not completely answer the question.
  - Stress test to assess for CAD may be medically necessary. Follow stress testing guideline: **Stress Testing with Imaging – Indications (CD-1.4).**
- Arteriovenous fistula with "high output" heart failure:
  - CT Chest with contrast (CPT® 71260) and/or CT Abdomen and/or CT Pelvis with contrast (CPT® 74160 or 72193 or 74177) **or**
  - CTA Chest (CPT® 71275) and/or CTA Abdomen and/or CTA Pelvis (CPT® 74175 or CPT® 72191 or CPT® 74174) **or**
  - MRI Chest and/or MRI Abdomen and/or MRI Pelvis without and with contrast (CPT® 71552 and/or 74183 and/or 72197) **or**
  - MRA Chest and/or MRA Abdomen and/or MRA Pelvis (CPT® 71555 and/or CPT® 74185 and/or CPT® 72198)
- Right-sided congestive heart failure can be a manifestation of pulmonary hypertension or serious lung disease.
  - CT Chest (CPT® 71260) or CTA Chest (CPT® 71275) to evaluate for recurrent pulmonary embolism

Evidence Discussion

- Congestive heart failure is a complex clinical syndrome with signs and symptoms that are a result of structural and/or functional impairment of ventricular ejection or filling which results in objective evidence of pulmonary or systemic congestion.
- Identification of the etiology of the cardiac dysfunction is crucial in the diagnosis of heart failure (HF) to determine subsequent management.
- Evaluation of HF usually entails multiple different diagnostic tools incorporating tools such as echocardiogram, stress testing, genetic testing, nuclear imaging, CT/ MRI imaging, endomyocardial biopsy and cardiac catheterization.
- Treatment of HF is targeted towards treating the underlying cause, improving the function and structure of the heart, and reducing mortality and morbidity. This not only includes medications but may also entail the use of cardiac resynchronization

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

devices, monitoring devices, ventricular assist devices, cardiothoracic surgery, and heart transplant.

Myocardial Sympathetic Innervation Imaging in Heart Failure (CD-3.6)

- Nuclear imaging using I-123-meta-iodobenzylguanidine (I-123-mIBG) in an attempt to image increased myocardial sympathetic activity is considered to be experimental and investigational.
- The AMA has established the following set of Category III codes to report these studies:
  - CPT® 0331T Myocardial sympathetic innervation imaging, planar qualitative and quantitative assessment
  - CPT® 0332T Myocardial sympathetic innervation imaging, planar qualitative and quantitative assessment; with tomographic SPECT

Background and Supporting Information

In heart failure, the sympathetic nervous system is activated in order to compensate for the decreased myocardial function. Initially, this is beneficial. However, long-term this compensatory mechanism is detrimental and causes further damage.

Markers have been developed using radioactive iodine in an attempt to image this increased myocardial sympathetic activity. Currently, AdreView™ (Iodine-123 meta-iodobenzylguanidine) is the only FDA-approved imaging agent available for this purpose.

Evidence Discussion

I-123-meta-iodobenzylguanidine (MIBG) imaging of the sympathetic nerve activity of the heart has been proposed and approved for the identification of individuals with heart failure. However, its clinical utility has not found widespread acceptance, and its clinical usefulness remains in question. There are no societal guidelines for its routine use. The guidelines contain many other imaging platforms such as echocardiography, magnetic resonance imaging, perfusion, and metabolic imaging that have proven superior for the diagnosis and management of individuals with heart failure.

Left Ventricular Assist Devices (LVAD) (CD-9.4)

Left ventricular assist devices (LVAD) are implantable devices used in individuals with advanced heart failure refractory to medical therapy as a bridge to transplantation or as a destination therapy.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Pre-LVAD implant

The following imaging studies are medically necessary for preoperative evaluation prior to planned LVAD implant:

- TTE (CPT® 93306)
- 3D rendering for echocardiography (CPT® 76376 or 76377)
- Cardiac MRI (CPT® 75557 or 75561) and CMR velocity flow mapping (CPT® 75565)
- CT Chest (CPT® 71250 or 71260) or CTA Chest (CPT® 71275) or MRI Chest (CPT® 71552) or MRA Chest (CPT® 71555)
- CTA Abdomen and Pelvis (CPT® 74174) or MRA Abdomen and Pelvis (CPT® 74185 and 72198)
- CT Coronary Angiography (CPT® 75574) in individuals post-coronary artery bypass grafting to assess the location and course of the bypass grafts to guide the surgical approach
- Transesophageal echocardiography (CPT® 93312, 93320, 93325)
- Right heart catheterization (CPT® 93451) or Right and left heart catheterization (CPT® 93453)

Post LVAD implant

TTE (CPT® 93306) is medically necessary as follows:

- Post-implant at the following intervals:
  - 2 weeks
  - 1 month
  - 3 months
  - 6 months
  - 12 months
  - Every 6 months thereafter

CT

- CTA Chest (CPT® 71275) or CT Chest with contrast (CPT® 71260) is medically necessary for evaluation of LVAD malfunction.
- CT Chest without contrast (CPT® 71250) or CT Chest with contrast (CPT® 71260) is medically necessary for the evaluation of LVAD-related infections.

FDG PET/CT for LVAD driveline infection (CPT® 78815 orCPT® 78429)

- Early infection detection for LVAD drivelines is desirable, since once the infection extends to the cannula and pump pocket, eradication becomes difficult. CT findings are nonspecific and metal device artifacts of the driveline itself affects sensitivity.
- FDG PET/CT is medically necessary for suspected LVAD infection if other studies and examination remain inconclusive.
- See **FDG PET/CT for Infections (CD-6.5)**.

Cardiac Surgery Imaging (CD-13)

CD.CS.0013.A
v2.0.2026

Pre-surgical Cardiac Testing – General Information (CD-13.1)

- It is important to differentiate requests for preoperative CT imaging before cardiac surgery according to type of procedure planned:
  - Primary cardiac operation – individuals who have not had prior heart surgery
  - Redo procedures – individuals who have had a prior procedure (it is important to determine the type of procedure as this may impact which modality is most appropriate for the pre-operative assessment)
  - Minimally invasive procedures, such as minimally invasive aortic valve operations, minimally invasive or robotic mitral operations, TAVR, MitraClip™ or other percutaneous valve procedures (such as valve in valve aortic or mitral, percutaneous tricuspid and TMVR which will be increasing in the future)
- In re-operative cardiac surgery, the benefit of preoperative CT is to assess for aortic calcifications, to evaluate the anatomic relationships in the mediastinum, such as the location of the various cardiac chambers and great vessels and proximity to the sternum, and to assess for the location of prior bypass grafts. Information can then be used to change the operative strategy including non-midline approach, peripheral vascular exposure, and alternative cannulation sites and for establishing cardiopulmonary bypass before re-sternotomy. These techniques can result in decreased incidence of intraoperative injury to heart, great vessels and prior bypass grafts and lower rates of postoperative stroke. IV contrast is necessary with these studies to delineate the anatomic structures. However, in individuals with renal insufficiency, the provider might choose to forgo the contrast if they do not want to contrast load the individual prior to placing them on the heart-lung machine.
- Aortic atherosclerosis is recognized as the single most important determinant of postoperative stroke. There is evidence to support that preoperative CT is associated with lower postoperative stroke rates and mortality after primary cardiac surgery.
  - CT Chest without contrast (CPT® 71250) can be performed pre-operatively to allow the surgeon to:
    - visualize the extent and location of aortic atherosclerosis
    - change the operative strategy such as those problematic areas are avoided

Click Here to Return to the Main TOC

Primary Cardiac Surgery – No Previous Cardiac Surgery (CD-13.2)

- CT Chest without contrast (CPT® 71250) to evaluate for the presence of ascending aortic calcification may be medically necessary prior to primary cardiac surgery when there is documented high risk for aortic calcification including any of the following:
  - aortic calcification on chest x-ray or other diagnostic test (TEE, fluoroscopy, etc.)
  - calcific aortic stenosis
  - end stage renal disease (dialysis)

Re-operative Cardiac Surgery (CD-13.3)

- Individuals undergoing re-operative cardiac surgery may undergo **one** of the following tests for preoperative assessment:
  - CT Chest with contrast
  - CTA Chest
  - CCTA only if prior CABG (this might be in addition to CT with contrast as CCTA will not show the extent of the thoracic aorta that needs to be visualized)
  - CT Heart usually does not provide the necessary information and is not medically necessary routinely.

Minimally Invasive or Robotic Cardiac Surgery (CD-13.4)

- CTA Chest CPT® 71275 (or CT Chest with contrast CPT® 71260) and CTA Abdomen and Pelvis CPT® 74174 (or CT Abdomen and Pelvis with contrast CPT® 74177) are medically necessary for pre-operative assessment of suitability for the approach and for procedural planning of arterial and venous cannulation and cardiopulmonary bypass for individuals being considered for minimally invasive or robotic cardiac surgical procedures including the following:
  - valve repair or replacement
  - coronary artery bypass graft surgery
  - aortic root or ascending aorta repair
  - resection of intracardiac tumor, or thrombus or vegetation
  - open lead extraction
  - atrial septal defect repair

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Transcatheter Valve Interventions (CD-13.5)

Transcatheter Mitral Valve Repair (mitral valve clip)

- The following imaging may be used to determine if an individual is eligible for the procedure:
  - Transthoracic echo (TTE) (CPT® 93306) with or without 3D rendering
  - Transesophageal echo with or without 3D rendering
  - Heart catheterization, including right heart catheterization if requested
  - CCT (CPT® 75572) is recommended in individuals with radiation-induced valve disease
- CTA/CTV of Chest, Abdomen, and Pelvis is not medically necessary prior to planned transcatheter mitral valve repair.
- Post-procedure transthoracic echo (TTE) can be performed at the following intervals:
  - 1 month
  - 6 months
  - 1 year
  - then annually

Transcatheter Tricuspid Valve Replacement

Pre-procedure imaging

- The following imaging studies are medically necessary to determine eligibility and for procedure planning Pre-Transcatheter Tricuspid Valve Replacement (TTVR):
  - Cardiac CT CPT® 75572
  - CTV Chest CPT® 71275
  - CTV Abdomen and Pelvis CPT® 74174

Note:

Cardiac CT (CPT® 75572) is recommended in individuals with radiation-induced valve disease.

Post-procedure follow up

- TTE (CPT® 93306) is medically necessary post-procedure at the following intervals:
  - 1 month
  - 6 months
  - 1 year
  - then annually

Proprietary Information of UnitedHealthcare.

CT Imaging in Transcatheter Aortic Valve Replacement (TAVR)

Pre-TAVR imaging

Pre-aortic valve replacement

- Once the decision has been made for aortic valve replacement, the following may be used to determine if an individual is a candidate for TAVR:
  - CTA Chest (CPT® 71275), Abdomen and Pelvis (combination code CPT® 74174) are medically necessary; and
  - CT Cardiac (CPT® 75572) is medically necessary to measure the aortic annulus; or
  - Coronary CTA (CCTA CPT® 75574) is medically necessary to both measure the aortic annulus and assess the coronary arteries in lieu of heart catheterization.
- A repeat diagnostic left heart catheterization is **not** medically necessary when the individual is undergoing a transcatheter aortic valve replacement (TAVR).

Transfemoral access not feasible

Alternative imaging can be obtained to evaluate vascular access for TAVR in individuals for whom it is documented either via the office note or prior imaging that transfemoral access would not be feasible due to **any** of the following exclusion criteria:

- small vessels
- highly calcified vessels
- stenosed or occluded vessels
- prior aortoiliac vascular intervention

Imaging is medically necessary based on the documented intended access site (transaxillary or transcarotid) and should be of the involved body areas. The following studies are medically necessary based on the documented planned access site:

- CTA of the Head (CPT® 70496) and/or Neck (CPT® 70498) for transcarotid access
- CTA of the Chest (CPT® 71275) and/or Upper Extremity (CPT® 73206) for transaxillary access

Post-TAVR imaging

CT Cardiac (CPT® 75572) is medically necessary:

- if any of the post-TAVR TTEs are indeterminate or raises a concern about any of the following:
  - valve thrombosis
  - infective endocarditis
  - structural degeneration
- when a Valve-in-Valve implantation or surgical re-do AVR is being contemplated

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Routine CT surveillance or follow up for incidental Hypoattenuated Leaflet Thickening (HALT) with or without restricted leaflet motion, also referred to as Hypoattenuation Affecting Motion (HAM), is NOT medically necessary.

Evidence Discussion

The ability of the cardiac CT technology to provide a tomographic view of the cardiovascular system has resulted in its ubiquitous adoption in the pre-procedure planning for almost all cardiac structural interventions. Specifically, cardiac CT circumvents the image window limitation of echocardiography, allows high definition visualization of the posterior structures, and facilitates pre-procedural planning for pulmonary vein isolation, coronary sinus pacer leads insertion, and left atrial appendage occlusion device implantation, among other trans-catheter structural interventions.

In non-interventional settings, cardiac CT provides an alternative to cardiac MRI when structural information cannot be adequately obtained by an echocardiography. Most notably, the evaluation of a cardiac mass, extent of pericardial disease, complex congenital heart disease and cardiomyopathy, can be performed by a cardiac CT when cardiac MRI is not available or contraindicated.

Trans-catheter Aortic Valve Replacement (TAVR)

The success of a Trans-catheter Aortic Valve Replacement (TAVR) procedure is contingent upon a meticulous pre-TAVR planning imaging study where cardiac CT allows accurate annulus sizing, coronary heights measurement, and calcification distribution evaluation, in addition to access site planning. Post-operatively, clinically suspected complications such as thrombus formation, infective endocarditis, or structural degeneration can be confirmed on a cardiac CT; a routine surveillance strategy, however, is not supported because of unclear or even potentially harmful outcome of treating incidental findings.

Transcatheter Mitral Valve Repair (mitral valve clip)

In non-interventional settings, cardiac CT provides an alternative to cardiac MRI when structural information cannot be adequately obtained by an echocardiography. Most notably, the evaluation of a cardiac mass, extent of pericardial disease, complex congenital heart disease and cardiomyopathy, can be performed by a cardiac CT when cardiac MRI is not available or contraindicated. Percutaneous treatment of mitral regurgitation can be accomplished using venous access to apply a clip device (e.g., MitraClip currently FDA approved) to provide edge-to-edge mitral leaflet coaptation, approximating opposing sections of the anterior and posterior mitral valve leaflets. FDA approved indications include treatment for individuals with symptomatic, moderate to severe, or severe primary mitral regurgitation whose surgical risks are prohibitive, as well as symptomatic moderate to severe or severe secondary mitral

Click Here to Return to the Main TOC

regurgitation who have failed optimal medical therapy. This therapy should include, if medically necessary, cardiac resynchronization therapy.

Transcatheter Mitral & Tricuspid Valve Replacement

Transcatheter Tricuspid Valve Replacement device (EVOQUE) is currently FDA approved. In individuals being considered for transcatheter tricuspid or mitral valve replacement, Cardiac CT (CPT® 75572) provides detailed imaging of the valve annulus including measurement of valve annulus to guide selection of the appropriate-sized valve. CTV Chest (CPT® 71275) and CTV Abdomen and Pelvis (CPT® 74174) provide imaging of the iliac veins and inferior vena cava to exclude stenosis or significant tortuosity and aid in determining eligibility and procedure planning.

Pulmonary Hypertension (PH) (CD-8.1)

CD.CS.0008.1.A
v2.0.2026

Pulmonary Hypertension Imaging indications

Transthoracic echocardiogram (TTE) (CPT® 93306) should be performed initially as it can help determine the probability of pulmonary hypertension.

Screening

A screening echocardiogram (TTE) for PH is medically necessary in individuals with documented history of **any** of the following:

- individuals pre-operatively for planned liver transplant
- individuals evaluated for transjugular portosystemic shunt
- portal hypertension
- liver disease with signs and symptoms of PH
- bronchopulmonary dysplasia

Annual screening echocardiogram (TTE) is medically necessary in individuals with a documented history of any of the following:

- systemic sclerosis (SSc)
- individuals with PH mutations (e.g., BMPR2)
- first-degree relatives of individuals with PH
- connective tissue disorder with symptoms consistent with PH
- individuals with TR velocity ≥2.8m/s, with no other findings on additional testing
- individuals being treated with medications associated with PH
- individuals who have a concern documented for PH and had a negative echocardiogram but still show signs or symptoms of PH

Follow-up testing is not medically necessary in individuals with TR velocity <2.8m/s and no other signs, symptoms, or risk factors of PH.

Initial imaging

Transthoracic echocardiogram (TTE) (CPT® 93306) is medically necessary for symptoms and signs of PH including **any** of the following:

- notes documenting clinical concern for pulmonary hypertension
- EKG findings concerning for PH such as **any** of the following:
  - right ventricular hypertrophy (RVH)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - right axis deviation
  - right atrial enlargement
- right ventricular hypertrophy or pulmonary artery dilation on other images
- history of pulmonary embolism with persistent or new onset DOE, or exercise limitation
- suspected PH in individuals with lung disease
- DOE in individuals with connective tissue disorder, HIV, portal hypertension, SSc.
- Symptoms of PH (**any** of the following):
  - breathlessness
  - SOB
  - decreased exercise tolerance
  - fatigue and rapid exhaustion
  - palpitations
  - dyspnea on bending forward
  - hemoptysis
  - exercise induced abdominal distention and nausea
  - weight gain due to fluid retention
  - syncope during or shortly after physical activity
  - exertional chest pain

Stress echo (CPT® 93350 or 93351) is medically necessary for **any** of the following:

- to assess for treatment in the setting of concomitant valvular disease
- as indicated by **Stress Testing with Imaging-Indications (CD-1.4)** or **Stress Echo-Indications Other than Ruling out CAD (CD-2.7)**
- There is documented concern for chronic thrombo-embolic pulmonary hypertension.

Cardiac MRI (CPT® 75557) is medically necessary when there is documentation of **any** of the following:

- TTE is equivocal or unclear (e.g., for RV function), and the information is needed for management.
- MRI and TTE may both be required for individuals who need RV pressure and function assessed, and prior RV function cannot be assessed by echocardiogram.
- MRI can replace TTE when the issue that makes the imaging by echo unclear is likely to be seen in future echocardiograms.

Other advanced imaging is medically necessary after TTE for the following:

- High-resolution CT Chest (CPT® 71250) is medically necessary in the setting of hypoxemia to rule out restrictive lung disorders such as pulmonary fibrosis.
- CTA Chest (CPT® 71275) or MRA Chest (CPT® 71555) is medically necessary to evaluate for suspected acute and/or chronic pulmonary embolism.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- V/Q scan (CPT® 78580-Pulmonary Perfusion Imaging or CPT® 78582-Pulmonary Ventilation (e.g., Aerosol or Gas) and Perfusion Imaging) is medically necessary to evaluate for any of the following:
  - suspected acute pulmonary embolism
  - to evaluate for chronic thromboembolic pulmonary hypertension at 3 to 6 months post pulmonary embolism if both of the following apply:
    - persistent or new onset dyspnea on exertion or exercise limitation
    - evidence of pulmonary hypertension on follow up echocardiogram
  - to evaluate for chronic thromboembolic pulmonary hypertension in individuals with pulmonary hypertension of uncertain etiology
- SPECT imaging (CPT® 78803) or SPECT/CT imaging (CPT® 78830) can be added to V/Q scan if requested.
- Transesophageal (TEE) contrast echocardiography or other imaging techniques (e.g., CT angiography, cardiac MRI) may be medically necessary, in addition to 2D Doppler and contrast examinations, to identify CHD to detect or exclude **any** of the following:
  - sinus venosus
  - atrial septal defects
  - patent ductus arteriosus
  - anomalous pulmonary venous connections

Indications for initial catheterization

Right heart catheterization (RHC) is medically necessary for **any** of the following:

- Echocardiogram findings
  - TR velocity ≥3.4m/second
  - TR velocity ≥2.9m/second and presence of other PH signs on echo or other testing, or risk factors or associated indications
- individuals with SSc where breathlessness remains unexplained (RHC is recommended despite normal echocardiogram)
- individuals with connective tissue disorder who have symptoms or concerns for PH with a negative or equivocal echocardiogram
- when recommended to determine if shunt closure is recommended due to congenital heart disease
- RHC if **moderate** to **severe** PH on echocardiogram
- RHC is medically necessary prior to starting PH medical therapy.
- Individuals with **low**-risk profile (based on an evidence based PAH Risk Score Calculator such as REVEAL 2.0, ESC/ERS & Compera 2.0) only need catheterization if medically necessary for another reason or equivocal studies.
- RHC is allowed when LHC indicated for separate indication.
- RHC preoperative for surgical intervention treating the cause of PH (MV, TV, AV, PV)
- Eisenmenger syndrome – RHC is medically necessary when requested by provider.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Left heart catheterization (LHC) or Right and left heart catheterization as per the following guidelines:

- **Evaluation of Conditions Other than Coronary Artery Disease (CD-7.7)**
- **Diagnostic Left Heart Catheterization (LHC) (CD-7.3)**

Repeat Testing

Follow-up echocardiogram (TTE) on individuals with PH is medically necessary for any of the following:

- every 6 months for surveillance of stable individuals with moderate or severe pulmonary hypertension (pulmonary artery systolic pressure ≥50mmHg)
- 3 months after any change in PH therapy
- prior to planned intubation (e.g., for elective surgery)
- prior to planned pregnancy
- during pregnancy as often as requested by provider
- anytime, without regard for the number or timing of previous echo studies to evaluate change in clinical signs or symptoms

Pulmonary embolism (PE)

- TTE is medically necessary 3 to 6 months post pulmonary embolism if **any** of the following apply:
  - persistent or new onset dyspnea on exertion, or exercise limitation
  - pulmonary hypertension or right ventricular dysfunction on initial echo at PE diagnosis
  - history of recurrent pulmonary embolism

RHC is medically necessary for known PH as follows:

- at baseline
- then every 6 months
- anytime for clinical changes or with treatment changes

Evidence Discussion

Pulmonary hypertension (PH) is a complex, chronic disease with multiple etiologies that requires extensive evaluation, including ECG (right ventricular hypertrophy with/without strain, right atrial dilatation); chest x-ray; arterial blood gas, pulmonary function testing, CT angiography based on the etiology.

PH can be subdivided into the following 5 groups based on the underlying cause:
- Pulmonary arterial hypertension (PAH)
- PH due to left heart disease
- PH due to lung disease
- Chronic thromboembolic PH (CTEPH)
- PH with unclear and/or multifactorial mechanisms

Probability of PH is assessed at initial evaluation:
- High probability:
  - TR velocity ≥3.4m/s
  - TR velocity between 2.9m/s to 3.4m/s and **one** of the following:
    - Right ventricle or pulmonary artery enlargement
    - Interventricular septum flattening
    - Right ventricular systolic dysfunction
- Intermediate probability:
  - TR velocity between 2.9m/s to 3.4m/s in the absence of other signs of PH
- Low probability:
  - TR velocity <2.8m/s

Peak TR velocity ≥2.8m/s may suggest PH; however, the presence or absence of PH cannot be reliably determined by TR velocity alone.

In addition to the tricuspid regurgitation velocity, other findings on echo can increase the probability of PH. Examples of these findings include:
- abnormal tricuspid annular plane systolic excursion (TAPSE)
- abnormal RV fractional area change (RV-FAC)
- abnormal RV free-wall strain
- abnormal tricuspid annulus velocity (S wave) derived from tissue Doppler imaging
- abnormal RV ejection fraction (RVEF) derived from 3D echocardiography

MRI can be a useful test especially with respect to RV function.

Right heart catheterization is the gold standard for diagnosing PH.

See **Severe Pulmonary Artery Hypertension (PH) and Eisenmenger Syndrome (CD-11.3.12)** for additional information regarding Eisenmenger Syndrome.

Pulmonary Vein Imaging – Indications (CD-8.2)

CD.CS.0008.2.A
v2.0.2026

Indications

- MRI Cardiac (CPT® 75557 or 75561), MRV Chest (CPT® 71555), CTV Chest (CPT® 71275), or CT Cardiac (CPT® 75572) to evaluate anatomy of the pulmonary veins:
  - prior to planned atrial fibrillation ablation/pulmonary vein isolation procedure
  - post-procedure between 3-6 months after ablation because of a 1% to 2% incidence of asymptomatic pulmonary vein stenosis
    - If no pulmonary vein stenosis is present, no further follow-up imaging is required.
    - If pulmonary vein stenosis is present on imaging following ablation and symptoms of pulmonary vein stenosis (usually shortness of breath) are present, imaging is considered medically necessary at 1, 3, 6, and 12 months.

Background and Supporting Information

The majority (81%) of pulmonary vein stenosis remain stable over 1 year. Progression occurs in 8.8%, and regression occurs in a small percentage.

Cardiac Imaging in Transplants (CD-16)

CD.ST.0001.6.A
v2.0.2026

Imaging Criteria

Codes Included

- SPECT MPI (CPT® 78451, 78452)
- Stress echocardiogram (CPT® 93350, 93351)
- Stress MRI (CPT® 75559, 75563)
- PET MPI (CPT® 78430, CPT® 78431, CPT® 78491, 78492)
- CT chest (CPT® 71250 or 71260)
- Ultrasound abdomen (CPT® 76700 or 76705)
- CT abdomen (CPT® 74150 or 74160)
- MRI abdomen (CPT® 74181 or 74183)
- Right heart catheterization (CPT® 93451)
- Right and left heart catheterization (CPT® 93453)
- Left heart catheterization (CPT® 93458)
- Echocardiogram (CPT® 93306)
- 3D echocardiogram (CPT® 93319, 76376, 76377)
- Strain imaging (CPT® 93356)

Non-cardiac transplants

- Stress Testing in Individuals for Non-Cardiac Transplant
  - Imaging stress testing every year (stress echocardiogram, SPECT MPI, stress MRI, or PET MPI per the transplant center's protocol) is medically necessary prior to transplant for candidates for any type of organ, bone marrow, or stem cell transplant. See **Kidney Transplant, Pre-Transplant Imaging Studies (AB-42.5)**.
  - An imaging stress test can be repeated annually after transplant for at least 2 years or within 1 year of a prior cardiac imaging study if there is evidence of progressive vasculopathy.
  - After 2 consecutive normal imaging stress tests, repeated testing is not medically necessary more often than every other year without evidence for progressive vasculopathy or new symptoms.
  - Stress testing after 5 years may proceed according to normal patterns of consideration.

Cardiac transplant

- Pre-Cardiac Transplant evaluation
  - One of the following is medically necessary for candidates being evaluated for heart transplant as suggested by the transplant center protocol:
    - SPECT MPI
    - Stress MRI
    - Stress echocardiogram
    - PET MPI
  - The following modalities are medically necessary for an individual being evaluated for cardiac transplant:
    - CT Chest (CPT® 71250 or 71260) **and**
    - Abdominal imaging with: Ultrasound Abdomen (CPT® 76700 or 76705) or CT Abdomen (CPT® 74150 or 74160) and/or MRI Abdomen (CPT® 74181 or 74183) **and**
    - Right heart catheterization (CPT® 93451) or Right and left heart catheterization (CPT® 93453) or left heart catheterization (CPT® 93458)
- Post-Cardiac transplant assessment of transplant CAD:
  - Echocardiogram, 3D echocardiogram (CPT® 93319, CPT® 76376, CPT® 76377,) and strain imaging (CPT® 93356) may be performed as needed per transplant protocol
  - **One** of the following imaging studies may be performed annually:
    - SPECT MPI (CPT® 78451, CPT® 78452)
    - Stress echocardiogram (CPT® 93350, CPT® 93351)
    - Stress MRI (CPT® 75559, CPT® 75563)
    - PET MPI (CPT® 78430, CPT® 78431, CPT® 78491, CPT® 78492)

Background and Supporting Information

Individuals who have undergone organ transplant are at increased risk for ischemic heart disease secondary to their medication. Risk of vasculopathy is 7% at 1-year, 32% at 5 years, and 53% at 10 years.

For individuals being evaluated for cardiac transplant, MRI may be performed as the initial abdominal imaging modality or for further evaluation after initial abdominal imaging with Ultrasound or CT.

Evidence Discussion

Stress testing with imaging is medically necessary to exclude the presence of significant coronary artery disease as part of evaluating candidacy for any type of organ, bone marrow, or stem cell transplant. While on the transplant waiting list, stress testing with imaging is medically necessary annually to exclude progression of coronary artery

disease. Stress testing with any imaging modality (stress echo, SPECT MPI, stress MRI, or stress cardiac PET perfusion) is supported per the transplant center's protocol. Recommendations regarding stress testing with imaging for pre-transplant evaluation are provided in established evidence-based medical specialty organization guidelines.

Stress testing with imaging also has a role in surveillance following cardiac transplant to evaluate for development of obstructive coronary artery disease due to cardiac allograft vasculopathy. Stress testing with any imaging modality (stress echo, SPECT MPI, stress MRI, or stress cardiac PET perfusion) is medically necessary annually post cardiac transplant. Recommendations regarding stress testing with imaging for post cardiac transplant surveillance are provided in established evidence-based medical specialty organization guidelines.

Hypertrophic Cardiomyopathy (HCM) (CD-14)

CD.CS.0014.A
v2.0.2026

HCM Imaging Indications

Hypertrophic Cardiomyopathy (HCM) is a clinical diagnosis, established by imaging with 2D echocardiography or cardiovascular magnetic resonance (CMR) showing a maximal end-diastolic wall thickness of ≥15 mm anywhere in the left ventricle, in the absence of another cause of hypertrophy in adults. More limited hypertrophy (13-14 mm) can be diagnostic, particularly when present in family members of an individual with HCM or in conjunction with a positive genetic test, and/or associated with typical dynamic outflow obstruction, or distinctly abnormal ECG patterns.

Screening

- For screening for inherited hypertrophic cardiomyopathy, see **Transthoracic Echocardiography (TTE-Indications (CD-2.2)** and **Frequency of Echocardiography Testing (CD-2.3).**

Initial imaging, new or changed symptoms

Transthoracic echocardiography (TTE)

- TTE is medically necessary for the initial evaluation of a genotype positive individual with inherited hypertrophic cardiomyopathy.

Transesophageal echocardiography (TEE) (CPT® 93312, 93320, 93325)

- TEE is medically necessary for the evaluation of individuals with hypertrophic cardiomyopathy if TTE is inconclusive for **any** of the following:
  - mitral regurgitation secondary to structural abnormalities of the mitral valve
  - subaortic membrane or aortic valve stenosis
- TEE is medically necessary for the pre-procedure planning for surgical myectomy or alcohol septal ablation evaluation of individuals with hypertrophic cardiomyopathy.

Stress echocardiogram

- Exercise stress echo (CPT® 93351 or 93350) is medically necessary for the detection and quantification of dynamic left ventricular outflow tract obstruction in symptomatic individuals with HCM who do **not** have a resting or provocable outflow tract gradient ≥50 mm Hg on TTE.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Stress echo can be repeated when there is documentation of **any** of the following:
  - In 1 to 2 years if the resting or provocable outflow tract gradient is <30 mm Hg on prior stress echo
  - Worsening symptoms
  - There has been a therapeutic change (e.g., change in medication, surgical procedure performed).

Cardiac CTA (CPT® 75574)

- Initial imaging study in individuals with hypertrophic cardiomyopathy and stable anginal symptoms
  - Chest discomfort is common in individuals with hypertrophic cardiomyopathy. The incidence of false positive myocardial perfusion imaging abnormalities is higher in these individuals, whereas the incidence of severe coronary artery stenosis is low.

Cardiac MRI (CMR)

- Cardiac MRI (CPT® 75557 or CPT® 75561) for assessment of global ventricular function, myocardial composition, and mass if a specific clinical question is left unanswered by a recent echocardiogram and results will affect patient management.

Left heart catheterization with coronary arteriography

- Left heart catheterization with coronary arteriography (CPT® 93458 or 93454) is medically necessary to rule out coronary artery disease prior to planned surgical myectomy for hypertrophic cardiomyopathy.

Surveillance imaging

- TTE is medically necessary every year when there is no change in clinical status or treatment.

Monitoring treatment

Repeat TTE (CPT® 93306) is medically necessary in individuals with Obstructive Hypertrophic Cardiomyopathy (HCM) for the following:

Mavacamten for obstructive hypertrophic cardiomyopathy

Initiation of treatment

- Baseline-at the beginning of treatment
- 4 weeks after treatment initiation
- 8 weeks after treatment initiation
- 12 weeks after treatment initiation
- Then every 12 weeks while on mavacamten

Changes in treatment

- 4 weeks after any interruption of treatment (any missed dose)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- After any dosage change (including restart of treatment):
  - 4 weeks after dosage change
  - 12 weeks after dosage change
- After initiating a weak CYP2C19 inhibitor (e.g., omeprazole) or moderate CYP3A4 inhibitor (e.g., ciprofloxacin):
  - 4 weeks after start of medication
  - 12 weeks after start of medication
- At any time regardless of timing of prior echo when there are new cardiac signs or symptoms, or worsening of clinical status

Post- Septal Reduction Therapy (SRT)

TTE is medically necessary within 3 to 6 months after SRT (surgical myectomy or alcohol septal ablation) to evaluate the procedural results in individuals with hypertrophic cardiomyopathy

Proprietary Information of UnitedHealthcare.

General Guidelines (CRID-1.0)

CID.AD.101.A
v2.0.2026

Terms used in this guideline

Abbreviations

ACE inhibitor	Angiotensin-converting enzyme inhibitor
AMI	Acute myocardial infarction
ARVC	Arrhythmogenic right ventricular cardiomyopathy
AV	Atrioventricular
CC	Complications/comorbid conditions
CHF	Congestive heart failure
CM	Cardiomyopathy
CRT	Cardiac resynchronization therapy
EP	Electrophysiology
GDMT	Guideline-directed medical therapy
HCM	Hypertrophic cardiomyopathy
HFpEF	Heart Failure with Preserved Ejection Fraction
HFrEF	Heart Failure with Reduced Ejection Fraction
HV Interval	His-ventricular Interval
ICD	Implantable cardioverter defibrillator

Definitions

NYHA Heart Failure Definitions	**class I** - No limitation of physical activity. Ordinary physical activity does not cause undue fatigue, palpitation, or dyspnea. **class II** - Slight limitation of physical activity. Comfortable at rest. Ordinary physical activity results in fatigue, palpitation, or dyspnea. **class III** - Marked limitation of physical activity. Comfortable at rest. Less than ordinary activity causes fatigue, palpitation, or dyspnea. **class IV** - Unable to carry on any physical activity without discomfort. Symptoms of heart failure may be present even at rest. If any physical activity is undertaken, discomfort is increased.
Abnormal blood pressure response to exercise	Flat response/failure to augment; rise then fall during exercise; vasoactive cardiovascular drugs may result in an abnormal blood pressure response to exercise
Ambulatory class IV CHF	Class IV heart failure with: 1) no active acute coronary syndrome; 2) no inotropes; and 3) on OMT
Cardiomyopathy	A disease that affects the heart muscle, making it harder for the heart to pump blood to the rest of the body. It is further defined based on the type of change in the heart muscle including: • hypertrophic - muscle becomes thicker • dilated -muscle becomes weaker and stretched out • nondilated - muscle develops scarring or abnormal tissue • restrictive - muscle becomes stiff and less flexible

Click Here to Return to the Main TOC

Hypertrophic cardiomyopathy	Hypertrophic Cardiomyopathy (HCM) is a clinical diagnosis, established by imaging with 2D echocardiography or cardiovascular magnetic resonance (CMR) showing a maximal end-diastolic wall thickness of ≥15 mm anywhere in the left ventricle, in the absence of another cause of hypertrophy in adults. More limited hypertrophy (13–14 mm) can be diagnostic, particularly when present in family members of a patient with HCM or in conjunction with a positive genetic test, and/or associated with typical dynamic outflow obstruction, or distinctly abnormal ECG patterns.
Incessant VT	Frequent recurrences of ongoing hemodynamically stable VT
Ischemic Cardiomyopathy	Decreased ability of the heart to pump blood properly caused by damage or scarring of the heart muscle from reduced blood supply to the heart (i.e., myocardial infarction or coronary artery disease)
Long QT Syndrome (LQTS)	A congenital disorder characterized by a prolongation of the QT interval on ECG and a propensity to ventricular tachyarrhythmias, which may lead to syncope, cardiac arrest, or sudden death. The QT interval on the ECG, measured from the beginning of the QRS complex to the end of the T wave, represents the duration of activation and recovery of the ventricular myocardium. QT intervals corrected for heart rate (QTc) longer than 0.44 seconds are generally considered abnormal, though a normal QTc can be more prolonged in females (up to 0.46 sec).The Bazett formula is the formula most commonly used to calculate the QTc, as follows: QTc = AT/square root of the R-R interval (in seconds).
Non-Compaction Cardiomyopathy	A rare congenital cardiomyopathy that affects children and adults. It results from the failure of myocardial development during embryogenesis. It is also called spongiform cardiomyopathy. Symptoms are often a result of a poor pumping performance by the heart. The disease can be associated with other problems with the heart and the body.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Non-Sustained Ventricular Tachycardia (NSVT)	Three or more consecutive ventricular beats at a rate of greater than 120 beats/min with a duration of less than 30 seconds
Nonischemic Cardiomyopathy	Decreased ability of the heart to pump blood properly not caused by coronary artery disease or ischemic injury
Optimal Medical Therapy (OMT)	Optimal medical therapy for heart failure includes 3 months of **all** of the following: • Beta-blocker • Mineralocorticoid antagonist (MRA) • One of the following: ◦ ACE inhibitor ◦ angiotensin II receptor blocker ◦ angiotensin receptor-neprilysin inhibitor **Note:** SGLT2i treatment improves prognosis in heart failure. Due to concerns over patient access, cost, and patient tolerance, although recommended for heart failure, the use is not mandatory to meet OMT. If OMT is not tolerated due to documented adverse effects (hypotension, renal dysfunction, or electrolyte imbalances) this does not preclude ICD eligibility.
Structural Heart Disease	A structural or functional abnormality of the heart, or of the blood vessels supplying the heart, that impairs its normal functioning.
Sudden Cardiac Arrest (SCA)	The abrupt loss of all heart activity
TAVR (TAVI)	A minimally invasive procedure to treat aortic valve stenosis
Wolff-Parkinson-White (WPW) syndrome	A cardiac condition where an accessory pathway allows electrical conduction between the heart chambers outside of the normal AV node route and creates a re-entry circuit, which can lead to supraventricular tachycardia (SVT), atrial fibrillation (AF), ventricular fibrillation (VF), and sudden cardiac death.

Health Equity Consideration

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

General requirements

Current clinical information, which may include history, physical examination, symptoms, laboratory results, and imaging reports, are necessary for determining the medical necessity of implantable cardiac devices.

- The information provided should have clinical relevance to the request.
- If the information provided makes no reference to the potential indication for the request, then the medical necessity for the procedure(s) cannot be supported.
- Requests for a device when a same or similar device has already been placed is not supported without clear documentation that fulfills guideline criteria.

Procedures should be requested after initial consultation and physician treatment planning that includes full counseling of the individual with shared decision-making.

Removal and replacement (CRID-1.2)

- Generator replacement (CPT® 33212, 33213, 33221, 33227, 33228, 33229, 33230, 33231, 33240, 33262, 33263, 33264, 0614T, 0801T, 0802T, 0803T) with a same or similar device is medically necessary when:
  - Interrogation shows device is nearing Elective Replacement Indicator (ERI) or End of Life (EOL).
  - Interrogation report documents the device is not functioning correctly and requires replacement.

Evidence Discussion

The decision to replace a cardiac implantable device at elective replacement indicator is shared between the individual with the implanted device and the treating physician. Because clinical situations may change, indications should be reconsidered based on the most recent guidelines to evaluate for continuance of therapy or changing the type of device. For example, currently, there insufficient data regarding ICD replacement in

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

individuals who have received a primary prevention ICD, but have not experienced a clinically relevant arrhythmia since the device was placed (Russo et al. 2023). Clinical situations and an individuals understanding of their options may change. It is essential in the shared-decision process to ensure the individual is aware of any change in clinical status or change in evidence that may impact the decision to replace a cardiac device.References

Permanent Pacemaker Implantation (CRID-7)

CID.PM.107.A
v2.0.2026

Codes included

Description	CPT®
Insertion of new or replacement of permanent pacemaker with transvenous electrode(s); atrial	33206
Insertion of new or replacement of permanent pacemaker with transvenous electrode(s); ventricular	33207
Insertion of new or replacement of permanent pacemaker with transvenous electrode(s); atrial and ventricular	33208
Upgrade of implanted pacemaker system, conversion of single chamber system to dual chamber system (includes removal of previously placed pulse generator, testing of existing lead, insertion of new lead, insertion of new pulse generator)	33214

Indications for Permanent Pacemaker (CRID-7.1)

Sinus node dysfunction

Permanent pacemaker implantation is medically necessary for any of the following:

- Symptomatic non-reversible sinus node dysfunction as evidenced by **both** of the following:
  - Documented sinus node dysfunction including one of the below:
    - Sinus bradycardia at rate less than 50 beats per minute
    - Sinus pauses greater than 3 seconds
  - Symptoms attributable to non-reversible sinus node dysfunction including **one** of the below:
    - Syncope or pre-syncope
    - Heart failure symptoms
    - Exertional fatigue and impaired exercise tolerance

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Sinus bradycardia at rate less than 40 beats per minute and symptoms possibly related to bradycardia
- Symptomatic sinus bradycardia (as defined above) is a consequence of essential medical management and continued treatment is clinically necessary
- Symptoms attributable to bradycardia as listed above and evidence of tachy-brady syndrome (sinus bradycardia, ectopic atrial bradycardia, or sinus pause alternating with periods of atrial flutter or atrial fibrillation)
- Symptomatic chronotropic incompetence defined as limitations in activity due to the inability of the heart to increase its rate during exercise to achieve 80% of maximum predicted heart rate (220-age).

Atrioventricular block (AVB)

Permanent pacemaker implantation is medically necessary for any of the following:

- AVB including one of the below, with or without symptoms:
  - Second-degree Mobitz type II
  - High-grade (greater than or equal to 2 consecutive P waves at a constant physiologic rate that do not conduct to the ventricles)
  - Third-degree (complete heart block)
- Any degree of AVB with one of the following symptoms that are clearly attributable to the AVB:
  - Syncope or pre-syncope
  - Heart failure symptoms
  - Exertional fatigue and impaired exercise tolerance
- Third-degree and advanced second-degree AV block at any anatomic level associated with sustained or non-sustained ventricular tachycardia (ventricular rhythm at rate greater than 100 bpm lasting greater than or equal to 3 consecutive beats) presumed due to AV block
- Marked first-degree AVB (PR interval greater than or equal to 0.3 seconds) or second-degree AVB with symptoms similar to those of pacemaker syndrome
- Symptomatic AVB as a consequence of guideline directed management and continued treatment is clinically necessary
- Persistent or permanent atrial fibrillation and symptomatic bradycardia including one of the following:
  - Rate less than 50 beats per minute
  - Regular QRS intervals indicating complete atrioventricular block (AVB)
- Second degree AV block with a documented pause of greater than or equal to 5 seconds during waking in the presence of atrial fibrillation, with or without symptoms
- Second degree AV block with documented periods of asystole greater than or equal to 3.0 seconds in the presence of sinus rhythm, with or without symptoms

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Second-degree AVB noted to be located at intra-His or infra-His levels at electrophysiology study (EPS), with or without symptoms
- Any AVB indication listed above occurring after acute myocardial infarction that does not resolve within 5 days
- Congenital complete or high-degree AVB in the presence of any of the following:
  - Symptoms related to bradycardia such as syncope, pre-syncope, heart failure symptoms, exertional fatigue, or impaired exercise tolerance
  - Wide QRS escape rhythm
  - Mean daytime heart rate below 50 bpm
  - Pauses greater than 3 times the cycle length of the ventricular escape rhythm
  - Complex ventricular ectopy
  - Prolonged QT interval
  - Ventricular dysfunction, ventricular dilatation or significant mitral regurgitation

Conduction Disorders with 1:1 Atrioventricular Conduction

Permanent pacemaker implantation is medically necessary for any of the following:

- Individuals with syncope and bundle branch block and one of the following at electrophysiology study (EPS):
  - Baseline HV interval greater than or equal to 70 ms
  - Second- or third-degree intra- or infra-Hisian block during incremental atrial pacing
- Alternating bundle branch block, with or without symptoms
- HV interval greater than or equal to 100 milliseconds noted at EPS, with or without symptoms
- Intra-Hisian- or infra-Hisian block noted at EPS, with or without symptoms

Recurrent syncope

Permanent pacemaker implantation is medically necessary for individuals with recurrent syncope and any of the following:

- Spontaneous documented symptomatic asystolic pause greater than 3 seconds due to sinus arrest or atrioventricular block (AVB)
- Spontaneous documented asymptomatic asystolic pause greater than 6 seconds due to sinus arrest or AVB
- Cardioinhibitory carotid sinus syndrome as documented by one of the below:
  - Syncope caused by spontaneously occurring carotid sinus stimulation
  - Carotid sinus pressure that induces syncope and/or ventricular asystole of greater than or equal to 3 seconds
- Syncope associated with asystole of greater than or equal to 3 seconds during tilt testing

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Bundle branch block and one of the following at electrophysiology study (EPS):
  - Baseline HV interval greater than or equal to 70 ms
  - Second- or third-degree intra- or infra-Hisian block during incremental atrial pacing
- Syncope after cardiac transplantation with or without documentation of bradyarrhythmia
- Recurrent Adam-Stokes syndrome

Peri-procedural and post-operative indications

Permanent pacemaker implantation is medically necessary for any of the following:

- Prior to a planned catheter ablation of the atrioventricular (AV) junction for one of the following:
  - Rate control strategy for management of atrial fibrillation
  - Supraventricular tachycardia resulting in tachycardia induced cardiomyopathy that is not controlled with ablation or medical therapy
- Post Transcatheter Aortic Valve Implantation (TAVI) for any of the following:
  - Complete or high-degree atrioventricular block (AVB) that persists for 24 to 48 hours after TAVI
  - New-onset alternating bundle branch block after TAVI
  - Pre-existing right bundle branch block (RBBB) and new conduction abnormality onset during or after (TAVI) such as:
    - Transient high-degree AVB
    - PR prolongation
    - QRS axis change
- Sinus node dysfunction or AVB associated with symptoms or hemodynamic instability occurring after cardiac surgery that does not resolve within 5 days
- Post cardiac transplant for any of the following:
  - Relative bradycardia that is prolonged or recurrent, which limits rehabilitation or discharge after postoperative recovery
  - Syncope with or without documentation of bradyarrhythmia

Neuromuscular diseases known to involve the heart

Permanent pacemaker implantation is considered medically necessary for progressive neuromuscular diseases known to involve the heart with any degree of atrioventricular (AV) block including first degree AV block or any fascicular block, with or without symptoms, because there may be unpredictable progression of AV conduction disease. Progressive neuromuscular diseases known to involve the heart include:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Myotonic muscular dystrophy
- Kearns-Sayre syndrome
- Erb dystrophy (limb-girdle muscular dystrophy)
- Peroneal muscular atrophy

Single Chamber Pacemaker Upgrade to Dual Chamber Pacemaker

Upgrade of a single-chamber ventricular pacemaker (VVI) to dual-chamber pacemaker (DDD) is medically necessary when **any** of the following conditions are present:

- Sinus node dysfunction, where atrial pacing is required to maintain chronotropic competence
- Atrioventricular (AV) conduction abnormalities, including first-degree, second-degree (Mobitz I or II), high-grade AV block, or complete heart block, where synchronized atrioventricular pacing is anticipated to improve hemodynamic performance
- Symptoms consistent with pacemaker syndrome (fatigue, hypotension, or syncope resulting from the loss of AV synchrony)

Permanent Pacemaker Implantation - Non-indications (CRID-7.2)

- Permanent pacemaker implantation is **not** medically necessary in any of the following settings:
  - Sinus node dysfunction when there is documentation of any of the following
    - Individual is asymptomatic
    - The symptoms suggestive of bradycardia have been clearly documented to occur in the absence of bradycardia
    - Sinus node dysfunction is due to nonessential drug therapy
  - Fascicular block without AV block or without symptoms concerning for AV block
  - Incidentally noted hypersensitive cardioinhibitory response to carotid sinus stimulation when the individual remains asymptomatic or has vague symptoms
  - Asymptomatic first-degree AV block
  - Asymptomatic type-1 second-degree AV block at the supra-His (AV node) level or that which is not known to be intra- or infra-Hisian
  - Asymptomatic transient AV block in the absence of intraventricular conduction defects or in isolated single fascicular block
  - Situational vasovagal syncope when avoidance behavior is effectively preventing syncopal episodes
  - Prior to Transcatheter Aortic Valve Replacement (TAVR) as a prophylactic measure in individuals with right bundle branch block (RBBB) when there is no indication for permanent pacing
  - For the purpose of cardiac contractility modulation (CCM)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Upgrade of a single chamber pacemaker (VVI) to a dual chamber pacemaker (DDD) is **not** medically necessary for the indication of persistent atrial fibrillation when it is **not** part of a planned rhythm control strategy.

Leadless Pacemaker (CRID-11.1)

CID.PM.111.A
v2.0.2026

Codes included

Description	CPT®
Transcatheter insertion of permanent dual-chamber leadless pacemaker, including imaging guidance (e.g., fluoroscopy, venous ultrasound, right atrial angiography, right ventriculography, femoral venography) and device evaluation (e.g., interrogation or programming), when performed; complete system (i.e., right atrial and right ventricular pacemaker components)	0795T
Transcatheter insertion of right atrial pacemaker component (when an existing right ventricular single leadless pacemaker exists to create a dual-chamber leadless pacemaker system)	0796T
Transcatheter insertion of right ventricular pacemaker component (when part of a dual-chamber leadless pacemaker system)	0797T
Transcatheter insertion of permanent single-chamber leadless pacemaker, right atrial, including imaging guidance (e.g., fluoroscopy, venous ultrasound, right atrial angiography and/or right ventriculography, femoral venography, cavography) and device evaluation (e.g., interrogation or programming), when performed	0823T
Transcatheter insertion or replacement of permanent leadless pacemaker, right ventricular, including imaging guidance (e.g., fluoroscopy, venous ultrasound, ventriculography, femoral venography) and device evaluation (e.g., interrogation or programming), when performed	33274

Indications for Leadless Pacemaker

Leadless right ventricular pacemaker (CRID-11.1.1)

CPT® 33274

Permanent right ventricular leadless pacemaker implant is medically necessary when **both** of the following are met:

- The individual meets **any** of the following indications for leadless right ventricular pacemaker:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Symptomatic paroxysmal or permanent high-grade AV block in the presence of Atrial Fibrillation (AF)
  - Symptomatic paroxysmal or permanent high-grade AV block in the absence of AF, as an alternative to dual chamber pacing, when atrial lead placement is considered difficult, high risk, or not deemed necessary for effective therapy
  - Symptomatic bradycardia-tachycardia syndrome or sinus node dysfunction (sinus bradycardia or sinus pauses), as an alternative to atrial or dual chamber pacing, when atrial lead placement is considered difficult, high risk, or not deemed necessary for effective therapy
- The following contraindications for leadless pacemaker are **not** present:
  - An implanted inferior vena cava filter
  - A mechanical tricuspid valve

Leadless dual chamber pacemaker system (CRID-11.1.2)

CPT® 0795T

A leadless dual chamber pacemaker is considered not medically necessary when either of the following **contraindications** is present:
- An implanted inferior vena cava filter
- A mechanical tricuspid valve

Permanent dual chamber leadless pacemaker implant is medically necessary in an individual with no contraindications to a leadless pacemaker, when one of the following indications for a permanent dual chamber pacemaker is documented:

Sinus node dysfunction

Permanent pacemaker implantation is medically necessary for any of the following:
- Symptomatic non-reversible sinus node dysfunction as evidenced by **both** of the following:
  - Documented sinus node dysfunction including one of the below:
    - Sinus bradycardia at rate less than 50 beats per minute
    - Sinus pauses greater than 3 seconds
  - Symptoms attributable to non-reversible sinus node dysfunction including **one** of the below:
    - Syncope or pre-syncope
    - Heart failure symptoms
    - Exertional fatigue and impaired exercise tolerance
- Sinus bradycardia at rate less than 40 beats per minute and symptoms possibly related to bradycardia
- Symptomatic sinus bradycardia (as defined above) is a consequence of essential medical management and continued treatment is clinically necessary

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Symptoms attributable to bradycardia as listed above and evidence of tachy-brady syndrome (sinus bradycardia, ectopic atrial bradycardia, or sinus pause alternating with periods of atrial flutter or atrial fibrillation)
- Symptomatic chronotropic incompetence defined as limitations in activity due to the inability of the heart to increase its rate during exercise to achieve 80% of maximum predicted heart rate (220-age).

Atrioventricular block (AVB)

Permanent pacemaker implantation is medically necessary for any of the following:

- AVB including one of the below, with or without symptoms:
  - Second-degree Mobitz type II
  - High-grade (greater than or equal to 2 consecutive P waves at a constant physiologic rate that do not conduct to the ventricles)
  - Third-degree (complete heart block)
- Any degree of AVB with one of the following symptoms that are clearly attributable to the AVB:
  - Syncope or pre-syncope
  - Heart failure symptoms
  - Exertional fatigue and impaired exercise tolerance
- Third-degree and advanced second-degree AV block at any anatomic level associated with sustained or non-sustained ventricular tachycardia (ventricular rhythm at rate greater than 100 bpm lasting greater than or equal to 3 consecutive beats) presumed due to AV block
- Marked first-degree AVB (PR interval greater than or equal to 0.3 seconds) or second-degree AVB with symptoms similar to those of pacemaker syndrome
- Symptomatic AVB as a consequence of guideline directed management and continued treatment is clinically necessary
- When part of a planned rhythm control strategy, persistent atrial fibrillation with symptomatic bradycardia including **either** of the following:
  - Rate less than 50 beats per minute
  - Regular QRS intervals indicating complete atrioventricular block (AVB)
- Second degree AV block with a documented pause of greater than or equal to 5 seconds during waking in the presence of atrial fibrillation, with or without symptoms
- Second degree AV block with documented periods of asystole greater than or equal to 3.0 seconds in the presence of sinus rhythm, with or without symptoms
- Second-degree AVB noted to be located at intra- or infra-His levels at electrophysiology study (EPS), with or without symptoms
- Any AVB indication listed above occurring after acute myocardial infarction that does not resolve within 5 days

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Congenital complete or high-degree AVB in the presence of any of the following:
  - Symptoms related to bradycardia such as syncope, pre-syncope, heart failure symptoms, exertional fatigue, or impaired exercise tolerance
  - Wide QRS escape rhythm
  - Mean daytime heart rate below 50 bpm
  - Pauses greater than 3 times the cycle length of the ventricular escape rhythm
  - Complex ventricular ectopy
  - Prolonged QT interval
  - Ventricular dysfunction, ventricular dilatation or significant mitral regurgitation

Conduction Disorders with 1:1 Atrioventricular Conduction

Permanent pacemaker implantation is medically necessary for any of the following:

- Individuals with syncope and bundle branch block and one of the following at electrophysiology study (EPS):
  - Baseline HV interval greater than or equal to 70 ms
  - Second- or third-degree intra- or infra-Hisian block during incremental atrial pacing
- Alternating bundle branch block, with or without symptoms
- HV interval greater than or equal to 100 milliseconds noted at EPS, with or without symptoms
- Intra-Hisian- or infra-Hisian block noted at EPS, with or without symptoms

Recurrent syncope

Permanent pacemaker implantation is medically necessary for individuals with recurrent syncope and any of the following:

- Spontaneous documented symptomatic asystolic pause greater than 3 seconds due to sinus arrest or atrioventricular block (AVB)
- Spontaneous documented asymptomatic asystolic pause greater than 6 seconds due to sinus arrest or AVB
- Cardioinhibitory carotid sinus syndrome as documented by one of the below:
  - Syncope caused by spontaneously occurring carotid sinus stimulation
  - Carotid sinus pressure that induces syncope and/or ventricular asystole of greater than or equal to 3 seconds
- Syncope associated with asystole of greater than or equal to 3 seconds during tilt testing
- Bundle branch block and one of the following at electrophysiology study (EPS):
  - Baseline HV interval greater than or equal to 70 ms

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - Second- or third-degree intra- or infra-Hisian block during incremental atrial pacing
- Syncope after cardiac transplantation with or without documentation of bradyarrhythmia
- Recurrent Adam-Stokes syndrome

Peri-procedural and post-operative indications

Permanent pacemaker implantation is medically necessary for any of the following:

- Prior to a planned catheter ablation of the atrioventricular (AV) junction for supraventricular tachycardia resulting in tachycardia induced cardiomyopathy that is not controlled with ablation or medical therapy
- Post Transcatheter Aortic Valve Implantation (TAVI) for any of the following:
  - Complete or high-degree atrioventricular block (AVB) that persists for 24 to 48 hours after TAVI
  - New-onset alternating bundle branch block after TAVI
  - Pre-existing right bundle branch block (RBBB) and new conduction abnormality onset during or after (TAVI) such as:
    - Transient high-degree AVB
    - PR prolongation
    - QRS axis change
- Sinus node dysfunction or AVB associated with symptoms or hemodynamic instability occurring after cardiac surgery that does not resolve within 5 days
- Post cardiac transplant for any of the following:
  - Relative bradycardia that is prolonged or recurrent, which limits rehabilitation or discharge after postoperative recovery
  - Syncope with or without documentation of bradyarrhythmia

Neuromuscular diseases known to involve the heart

Permanent pacemaker implantation is considered medically necessary for progressive neuromuscular diseases known to involve the heart with any degree of atrioventricular (AV) block including first degree AV block or any fascicular block, with or without symptoms, because there may be unpredictable progression of AV conduction disease. Progressive neuromuscular diseases known to involve the heart include:

- Myotonic muscular dystrophy
- Kearns-Sayre syndrome
- Erb dystrophy (limb-girdle muscular dystrophy)
- Peroneal muscular atrophy

Proprietary Information of UnitedHealthcare.

Leadless right atrial pacemaker (CRID-11.1.3)

CPT® 0823T

Permanent leadless right atrial pacemaker implant is medically necessary when **both** of the following are met:

- Symptomatic sinus node dysfunction (dizziness, syncope, shortness of breath) with normal AV and intraventricular conduction systems
- The following contraindications for leadless pacemaker are not present:
  - An implanted inferior vena cava filter
  - A mechanical tricuspid valve

General information

Right ventricular leadless pacemaker

The permanent right ventricular leadless pacemakers (CPT® 33274) consist of a single leadless device implanted directly into the right ventricle. The Medtronic Micra™ VR and Abbott Aveir™ VR right ventricular leadless pacemakers are capable only of VVI and VVIR pacing. The Medtronic Micra™ AV right ventricular leadless pacemaker is also capable of VDD pacing. The right ventricular leadless pacemakers do not have capability for atrial pacing. The estimated battery life is about 10 years

Dual chamber leadless pacemaker

In contrast to the right ventricular leadless pacemakers referred to above, the dual chamber leadless pacemaker (i.e., Abbott Aveir™ DR leadless pacemaker system) has dual-chamber sensing and pacing functionality. The Abbott Aveir™ DR leadless pacemaker system consists of two separate components: one implanted in the right atrium and the other in the right ventricle.

Indications for ICD implantation (CRID-2)

CID.ICD.002.A
v2.0.2026

Codes included

Description	CPT®
Insertion or replacement of permanent pacing cardioverter-defibrillator system with transvenous lead(s), single or dual chamber	33249
Insertion or replacement of permanent subcutaneous implantable defibrillator system, with subcutaneous electrode, including defibrillation threshold evaluation, induction of arrhythmia, evaluation of sensing for arrhythmia termination, and programming or reprogramming of sensing or therapeutic parameters when performed	33270

Secondary Prevention ICD indications (CRID-2.1)

Cardiac Arrest Survivors (CRID-2.1.1)

ICD implantation is medically necessary in a survivor of cardiac arrest in the setting of any of the following conditions:

- Cardiac arrest from hemodynamically unstable or sustained VT, polymorphic VT, or VF associated with an acute (less than 48 Hours) MI with **both** of the following conditions:
  - Obstructive CAD with coronary anatomy not amenable to revascularization
  - Ejection fraction less than or equal to 35%
- Cardiac arrest from hemodynamically unstable or sustained VT, polymorphic VT, or VF associated with acute (<48 hours) post-coronary revascularization when **both** of the following conditions exist:
  - No evidence for acute coronary occlusion, restenosis, acute infarct, or other clearly reversible cause
  - Ejection fraction is less than or equal to 35%
- Cardiac arrest from hemodynamically unstable or sustained VT, polymorphic VT, or VF associated with coronary artery disease with **both** of the following conditions:
  - No recent MI (less than or equal to 40 days) prior to arrest
  - No recent coronary revascularization (less than or equal to 3 months) prior to arrest

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Cardiac arrest from hemodynamically unstable or sustained VT, polymorphic VT, or VF during exercise testing when cardiac catheterization performed after the arrest results in **any** of the following:
  - Significant CAD not amenable to revascularization
  - Significant CAD identified and complete revascularization performed
  - Significant CAD identified and incomplete revascularization performed
- Cardiac arrest from hemodynamically unstable or sustained VT, polymorphic VT, or VF not associated with coronary artery disease in the setting of **any** of the following conditions:
  - Non-ischemic dilated cardiomyopathy
  - Myocardial sarcoidosis
  - Giant-cell myocarditis
- Cardiac arrest with idiopathic VF and a normal Ejection Fraction (greater than or equal to 50%) when no reversible causes have been identified including **all** of the following:
  - Pharmacologically induced sustained VT/VF
  - Sustained VT/VF with hypokalemia
  - Wolff-Parkinson-White (WPW) syndrome with VT/VF and successfully ablated pathway

Sustained VT/VF (CRID-2.1.2)

ICD implantation is medically necessary to treat an individual with sustained VT or VF in the setting of any of the following conditions:

- Sustained VT/VF with any of the following genetic diseases:
  - Congenital long QT syndrome
  - Short QT syndrome
  - Catecholaminergic polymorphic VT
  - Brugada syndrome
  - Arrhythmogenic Right Ventricular Cardiomyopathy (ARVC)
  - Hypertrophic cardiomyopathy
- Sustained hemodynamically stable monomorphic VT associated with **non-ischemic** dilated cardiomyopathy when **any** of the following conditions apply:
  - No ablation was performed
  - Ablation did not result in successful termination of all inducible VTs
  - All inducible VTs were successfully ablated and LVEF is less than or equal to 50%
  - Identified bundle branch re-entry was successfully ablated and LVEF is less than or equal to 35%

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Sustained hemodynamically stable monomorphic VT associated with **ischemic** structural heart disease (coronary artery disease with prior MI) when **any** of the following apply:
  - No ablation was performed
  - Ablation did not result in successful termination of all inducible VTs
  - All inducible VTs are successfully ablated and LVEF is less than or equal to 35%
  - Ejection fraction is less than or equal to 35%

Syncope (CRID-2.1.3)

ICD implantation is medically necessary to treat unexplained syncope in an individual with any of the following conditions:

- Long QT syndrome in an individual on beta blocker therapy
- Brugada pattern on ECG
- Catecholaminergic polymorphic VT in an individual on a beta blocker
- Coronary artery disease with a prior MI in the setting of **either** of the following:
  - LVEF 36%-49% and both of the following:
    - No Acute MI (less than or equal to 40 days)
    - Inducible sustained VT/VF on EP study
  - Ejection fraction less than or equal to 35%
- Non-ischemic structural heart disease and any of the following:
  - Left ventricular hypertrophy (LVH) with EF less than or equal to 35%
  - Non-ischemic dilated cardiomyopathy with ejection fraction less than or equal to 35%
  - Left ventricular non-compaction with ejection fraction less than 50%
  - Tetralogy of Fallot with prior corrective surgery
  - Hypertrophic cardiomyopathy
  - Arrhythmogenic Right Ventricular Cardiomyopathy (ARVC)

Evidence Discussion

Secondary prevention refers to an indication for an ICD exclusively for patients who have survived >1 cardiac arrest(s) or episode(s) of sustained VT or VF. A ventricular arrhythmia is considered sustained if it lasts >30 seconds or result in hemodynamically significant symptoms prior to that time (i.e., requiring cardioversion or defibrillation). Patients with cardiac conditions associated with a high risk of sudden cardiac death (SCD) who have unexplained syncope presumed to be the result of a self-terminating ventricular arrhythmia are also considered to have a secondary prevention indication.

Primary Prevention ICD Indications (CRID-2.2)

Ischemic Cardiomyopathy (CRID-2.2.1)

Primary prevention is an indication for an ICD to prevent SCD. It refers to use of ICDs in individuals who are at risk for, but have not yet had, an episode of sustained VT, VF, or cardiac arrest.

ICD implantation is medically necessary for primary prevention of sudden cardiac death (SCD) associated with ischemic cardiomyopathy in the setting of **any** of the following:

- Post-acute MI (less than or equal to 40 Days) with LVEF less than or equal to 30% in the setting of either of the following:
  - Complete revascularization after recent MI with PCI or CABG and **all** of the following:
    - Asymptomatic NSVT (greater than or equal to 4 days post-MI)
    - EPS with inducible VT
    - EPS performed after revascularization and less than 40 day post MI
  - Obstructive CAD not amenable to revascularization with **both** of the following:
    - Asymptomatic NSVT (greater than or equal to 4 days post-MI)
    - EPS with inducible sustained VT (EPS performed within 40 days of MI)
- Post-acute MI (less than or equal to 40 Days) LVEF 31% to 40% when all of the following apply:
  - Asymptomatic NSVT (greater than or equal to 4 days post-MI)
  - EPS with inducible sustained VT (if revascularized, EPS performed after revascularization, within 40 days of MI)
- Post-acute MI (less than or equal to 40 Days) and Pre-Existing Chronic Cardiomyopathy (greater than or equal to 3 Months) with any of the following:
  - LVEF less than or equal to 30% due to old infarction with functional class I-III
  - LVEF less than or equal to 35% with NYHA functional class II-III
- Post MI (greater than 40 Days) with any of the following conditions:
  - LVEF less than or equal to 35% and both:
    - NYHA functional class I, II, or III
    - No PCI/CABG within 3 months
  - LVEF 36%-40% with all of the following:
    - No PCI/CABG within 3 months
    - Asymptomatic NSVT
    - EPS with inducible sustained VT
  - PCI or CABG (less than or equal to 3 Months) with LVEF less than or equal to 35% on OMT for greater than or equal to 3 months prior to PCI/CABG

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Ischemic cardiomyopathy with LVEF less than or equal to 35% and either of the following:
  - Individual has completed greater than or equal to 3 months of **OMT**
  - Individual has completed less than 3 months of **OMT** with either of the following findings:
    - NSVT
    - EPS with inducible sustained VT

Post Myocardial Infarction (MI) Need for Pacemaker Therapy (CRID-2.2.2)

ICD implantation is considered medically necessary in individuals with ischemic cardiomyopathy and a need for post-MI pacemaker therapy when **both** of the following clinical conditions exist:

- LVEF less than or equal to 35% in the setting of **either** of the following:
  - Individual is post-acute MI (less than or equal to 40 Days)
  - Individual is post MI (greater than 40 Days) with PCI or CABG (greater than or equal to 3 Months)
- **Any** of the following indications for pacemaker exist:

Sinus node dysfunction

Permanent pacemaker implantation is medically necessary for any of the following:

- Symptomatic non-reversible sinus node dysfunction as evidenced by **both** of the following:
  - Documented sinus node dysfunction including one of the below:
    - Sinus bradycardia at rate less than 50 beats per minute
    - Sinus pauses greater than 3 seconds
  - Symptoms attributable to non-reversible sinus node dysfunction including **one** of the below:
    - Syncope or pre-syncope
    - Heart failure symptoms
    - Exertional fatigue and impaired exercise tolerance
- Sinus bradycardia at rate less than 40 beats per minute and symptoms possibly related to bradycardia
- Symptomatic sinus bradycardia (as defined above) is a consequence of essential medical management and continued treatment is clinically necessary
- Symptoms attributable to bradycardia as listed above and evidence of tachy-brady syndrome (sinus bradycardia, ectopic atrial bradycardia, or sinus pause alternating with periods of atrial flutter or atrial fibrillation)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Symptomatic chronotropic incompetence defined as limitations in activity due to the inability of the heart to increase its rate during exercise to achieve 80% of maximum predicted heart rate (220-age).

Atrioventricular block (AVB)

Permanent pacemaker implantation is medically necessary for any of the following:

- AVB including one of the below, with or without symptoms:
  - Second-degree Mobitz type II
  - High-grade (greater than or equal to 2 consecutive P waves at a constant physiologic rate that do not conduct to the ventricles)
  - Third-degree (complete heart block)
- Any degree of AVB with one of the following symptoms that are clearly attributable to the AVB:
  - Syncope or pre-syncope
  - Heart failure symptoms
  - Exertional fatigue and impaired exercise tolerance
- Third-degree and advanced second-degree AV block at any anatomic level associated with sustained or non-sustained ventricular tachycardia (ventricular rhythm at rate greater than 100 bpm lasting greater than or equal to 3 consecutive beats) presumed due to AV block
- Marked first-degree AVB (PR interval greater than or equal to 0.3 seconds) or second-degree AVB with symptoms similar to those of pacemaker syndrome
- Symptomatic AVB as a consequence of guideline directed management and continued treatment is clinically necessary
- Persistent or permanent atrial fibrillation and symptomatic bradycardia including one of the following:
  - Rate less than 50 beats per minute
  - Regular QRS intervals indicating complete atrioventricular block (AVB)
- Second degree AV block with a documented pause of greater than or equal to 5 seconds during waking in the presence of atrial fibrillation, with or without symptoms
- Second degree AV block with documented periods of asystole greater than or equal to 3.0 seconds in the presence of sinus rhythm, with or without symptoms
- Second-degree AVB noted to be located at intra-His or infra-His levels at electrophysiology study (EPS), with or without symptoms
- Any AVB indication listed above occurring after acute myocardial infarction that does not resolve within 5 days
- Congenital complete or high-degree AVB in the presence of any of the following:
  - Symptoms related to bradycardia such as syncope, pre-syncope, heart failure symptoms, exertional fatigue, or impaired exercise tolerance

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Wide QRS escape rhythm
- Mean daytime heart rate below 50 bpm
- Pauses greater than 3 times the cycle length of the ventricular escape rhythm
- Complex ventricular ectopy
- Prolonged QT interval
- Ventricular dysfunction, ventricular dilatation or significant mitral regurgitation

Conduction Disorders with 1:1 Atrioventricular Conduction

Permanent pacemaker implantation is medically necessary for any of the following:

- Individuals with syncope and bundle branch block and one of the following at electrophysiology study (EPS):
  - Baseline HV interval greater than or equal to 70 ms
  - Second- or third-degree intra- or infra-Hisian block during incremental atrial pacing
- Alternating bundle branch block, with or without symptoms
- HV interval greater than or equal to 100 milliseconds noted at EPS, with or without symptoms
- Intra-Hisian- or infra-Hisian block noted at EPS, with or without symptoms

Recurrent syncope

Permanent pacemaker implantation is medically necessary for individuals with recurrent syncope and any of the following:

- Spontaneous documented symptomatic asystolic pause greater than 3 seconds due to sinus arrest or atrioventricular block (AVB)
- Spontaneous documented asymptomatic asystolic pause greater than 6 seconds due to sinus arrest or AVB
- Cardioinhibitory carotid sinus syndrome as documented by one of the below:
  - Syncope caused by spontaneously occurring carotid sinus stimulation
  - Carotid sinus pressure that induces syncope and/or ventricular asystole of greater than or equal to 3 seconds
- Syncope associated with asystole of greater than or equal to 3 seconds during tilt testing
- Bundle branch block and one of the following at electrophysiology study (EPS):
  - Baseline HV interval greater than or equal to 70 ms
  - Second- or third-degree intra- or infra-Hisian block during incremental atrial pacing
- Syncope after cardiac transplantation with or without documentation of bradyarrhythmia

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Recurrent Adam-Stokes syndrome

Peri-procedural and post-operative indications

Permanent pacemaker implantation is medically necessary for any of the following:

- Prior to a planned catheter ablation of the atrioventricular (AV) junction for one of the following:
  - Rate control strategy for management of atrial fibrillation
  - Supraventricular tachycardia resulting in tachycardia induced cardiomyopathy that is not controlled with ablation or medical therapy
- Post Transcatheter Aortic Valve Implantation (TAVI) for any of the following:
  - Complete or high-degree atrioventricular block (AVB) that persists for 24 to 48 hours after TAVI
  - New-onset alternating bundle branch block after TAVI
  - Pre-existing right bundle branch block (RBBB) and new conduction abnormality onset during or after (TAVI) such as:
    - Transient high-degree AVB
    - PR prolongation
    - QRS axis change
- Sinus node dysfunction or AVB associated with symptoms or hemodynamic instability occurring after cardiac surgery that does not resolve within 5 days
- Post cardiac transplant for any of the following:
  - Relative bradycardia that is prolonged or recurrent, which limits rehabilitation or discharge after postoperative recovery
  - Syncope with or without documentation of bradyarrhythmia

Neuromuscular diseases known to involve the heart

Permanent pacemaker implantation is considered medically necessary for progressive neuromuscular diseases known to involve the heart with any degree of atrioventricular (AV) block including first degree AV block or any fascicular block, with or without symptoms, because there may be unpredictable progression of AV conduction disease. Progressive neuromuscular diseases known to involve the heart include:

- Myotonic muscular dystrophy
- Kearns-Sayre syndrome
- Erb dystrophy (limb-girdle muscular dystrophy)
- Peroneal muscular atrophy

Non-ischemic Cardiomyopathy (CRID-2.2.3)

ICD implantation is medically necessary for primary prevention of SCD associated with non-ischemic cardiomyopathy in the setting of **any** of the following conditions:

- Idiopathic non-ischemic cardiomyopathy when **all** of the following apply:
  - LVEF less than or equal to 35% after greater than or equal to 3 months of **OMT**
  - Age less than or equal to 85 years
  - Functional NYHA class I-III
- Non-ischemic cardiomyopathy with recent valve surgery or TAVR with **all** of the following:
  - Recent Valve surgery or TAVR (within 3 months)
  - LVEF less than or equal to 35%
  - Need for pacemaker and LV function felt not likely to improve
- Non-ischemic cardiomyopathy from other specific etiologies in the setting of **any** of the following conditions:
  - Giant-cell myocarditis regardless of the LVEF
  - Sarcoid heart disease when LVEF is less than or equal to 35%
  - Myotonic dystrophy when LVEF is less than or equal to 35%
  - Chagas disease when LVEF is less than or equal to 35%
- Peripartum cardiomyopathy when **both** of the following apply:
  - Individual has completed 3 or more months of OMT
  - LVEF of 35% or less is persistent for 3 or more months post-partum
- **Any** of the following genetic conditions with structural heart disease:
  - Hypertrophic cardiomyopathy with **1 or more** of the following risk factor(s):
    - LV wall thickness greater than or equal to 30mm
    - SCD in 1 or more first-degree relatives presumably caused by HCM
    - 1 or more episodes of unexplained syncope within the preceding 6 months
    - Spontaneous NSVT
    - Abnormal blood pressure response with exercise
  - Arrhythmogenic right ventricular dysplasia/CM
  - Evidence of structural cardiac disease with Lamin A/C mutation or other genetic ACM with LVEF less than or equal to 45%
- **Either** of the following genetic conditions without structural heart disease:
  - Catecholaminergic Polymorphic VT with **both** of the following:
    - Non-sustained VT
    - one of the following:
      - Not tolerating medical therapy (beta-blockers, flecainide, or propafenone)
      - Breakthrough non-sustained ventricular arrhythmia on medical therapy (beta-blockers, flecainide, or propafenone)
  - Brugada by ECG (Type I ECG Pattern) with inducible VT or VF at EPS

Proprietary Information of UnitedHealthcare.

Pre or Post Heart Transplant (CRID-2.2.4)

ICD implantation is medically necessary for primary prevention of SCD for **either** of the following indications:

- Individual is on waiting list for heart transplant (outpatient status)
- Individual is post heart transplant with multiple episodes of cellular or antibody-mediated rejection

ICD Non-indications (CRID-2.7)

Non-indications

ICD implantation is considered **not medically necessary** in any of the following settings:

- Incessant VT or VF (hemodynamically stable VT or VF continuing for hours)
- VF or VT is due to a reversible cause such as:
  - Severe electrolyte disturbance
  - Drug-induced Torsades de Pointes (TdP)
  - Acute, reperfused myocardial infarction with preserved ejection fraction
- In an ablation candidate without structural heart disease

Substernal implantable cardioverter-defibrillator (CRID-2.8)

CPT® 0571T

- Substernal implantable cardioverter-defibrillator systems involve inserting a defibrillator lead directly beneath the sternum anterior to the heart and is intended to provide anti-tachycardia pacing as well as post-shock pacing without intravenous leads.
- At this time, substernal implantable cardioverter-defibrillator systems are considered experimental, investigational, and unproven.

Evidence Discussion

ICD implantation is **not** medically necessary for individuals who do not have a reasonable expectation of survival with an acceptable functional status for at least one year, even if they meet ICD implantation criteria listed in this guideline.

Pediatric Implantable Cardioverter Defibrillator

CID.ICD.12.A
v2.0.2026

Pediatric ICD Indications (CRID-12)

General Information

The decision to manage a pediatric condition with an implantable cardioverter defibrillator should be shared between a pediatric electrophysiologist and an informed individual/guardian/parent. This includes education of the individual/guardian/parent on all available options/potential side-effects, including inaction. This is of particular importance in individuals with limited health literacy at risk for poor health outcomes. These guidelines have been developed based on the 2021 PACES Expert Consensus Statement on the Indications and Management of Cardiovascular Implantable Electronic Devices in Pediatric individuals and the 2024 AHA/ACC/AMSSM/HRS/PACES/SCMR Guideline for the Management of Hypertrophic Cardiomyopathy.

These guidelines are not considered to be all-inclusive but to provide a path to the current indications supported by the societies and evidence.

Coding

Description	CPT®
Insertion or replacement of permanent pacing cardioverter-defibrillator system with transvenous lead(s), single or dual chamber	33249
Insertion or replacement of permanent subcutaneous implantable defibrillator system, with subcutaneous electrode, including defibrillation threshold evaluation, induction of arrhythmia, evaluation of sensing for arrhythmia termination, and programming or reprogramming of sensing or therapeutic parameters when performed	33270

Implantable Cardioverter-defibrillator General Indications (CRID-12.0)

ICD implantation is considered medically necessary for survivors of pediatric sudden cardiac arrest (SCA) from ventricular tachycardia (VT) or ventricular fibrillation (VF) when both of the following have been addressed:

- completely reversible causes have been excluded

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- ICD is decided in consultation with an informed individual/guardian/parent to be more beneficial than alternative treatments that may significantly reduce the risk of SCA

ICD implantation is considered medically necessary for sustained VT that cannot be adequately controlled with medication and/or catheter ablation.

ICD therapy is considered medically necessary for primary prevention of SCA when all of the following conditions exist:

- decision has been made in consultation with an informed individual/guardian/parent
- the individual has a history of either of the following:
  - a genetic cardiovascular disease and risk factors for SCA
  - a pathogenic mutation and a family history of recurrent SCA

ICD replacement is considered medically necessary in a pediatric individual when indications have been reconsidered based on the most recent guidelines to evaluate for discontinuance of therapy.

Long QT Syndrome (LQTS) (CRID-12.1)

ICD implantation is considered medically necessary in individuals with LQTS in any of the following settings:

- survivors of SCA along with the use of beta-blockade
- individuals with symptoms (arrhythmic syncope or VT) when beta-blockade is either ineffective or not tolerated and cardiac sympathetic denervation or other medications are not considered effective alternatives
- primary prevention in individuals with established clinical risk factors and/or pathogenic mutation

Catecholaminergic Polymorphic Ventricular Tachycardia (CRID-12.2)

ICD implantation is considered medically necessary in individuals with a diagnosis of CPVT in any of the following settings:

- persistent cardiac arrest or arrhythmic syncope despite treatment with beta-blocker and flecainide or cardiac sympathetic denervation
- in combination with pharmacologic therapy with or without cardiac sympathetic denervation when aborted SCA is the initial presentation of CPVT
- documented polymorphic or bidirectional VT despite pharmacologic therapy with or without cardiac sympathetic denervation

Brugada Syndrome (BrS) (CRID-12.3)

ICD implantation is considered medically necessary in individuals with a diagnosis of BrS when there is a history of any of the following conditions:

- survivors of SCA

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- documented spontaneous sustained VT
- a spontaneous type I Brugada ECG pattern with a history of recent syncope presumed due to a ventricular arrhythmia
- syncope presumed due to a ventricular arrhythmia with a type I Brugada ECG pattern only with provocative medications

Hypertrophic Cardiomyopathy (HCM) (CRID-12.4)

ICD implantation is considered medically necessary in individuals with HCM in the setting of any of the following conditions:

- survivors of SCA
- spontaneous sustained VT
- ICD is decided after considering the potential complications of long-term ICD placement in consultation with an informed individual/guardian/parent to be more beneficial than alternative treatments in an individual with ≥1 primary risk factors including any of the following:
  - unexplained syncope
  - massive left ventricular hypertrophy
  - non-sustained VT
  - family history of early HCM-related SCD
- in individuals with HCM without the above risk factors but with secondary risk factors for SCA such as extensive LGE on cardiac MRI or systolic dysfunction

Arrhythmogenic Cardiomyopathies (ACM) (CRID-12.5)

ICD implantation is considered medically necessary in individuals in any of the following settings:

- individual has been resuscitated from SCA or sustained VT that is not hemodynamically tolerated
- in individuals with hemodynamically tolerated sustained VT, syncope presumed due to ventricular arrhythmia, or an LVEF less than or equal to 35%.
- in individuals with inherited ACM associated with increased risk of SCD based on an assessment of additional risk factors

Non-ischemic Dilated Cardiomyopathy (NIDCM) (CRID-12.6)

ICD implantation is considered medically necessary in individuals with NIDCM who either survive SCA or experience sustained VT not due to completely reversible causes.

ICD implantation is considered medically necessary in individuals with NIDCM and syncope or an LVEF ≤35% after less than or equal to 3 months of **OMT**.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Congenital Heart Disease (CHD) (CRID-12.7)

ICD implantation is considered medically necessary for individuals with CHD for any of the following reasons:

- survivors of SCA when evaluation to define the cause of the event does not reveal any completely reversible causes
- individuals with hemodynamically unstable sustained VT who have undergone hemodynamic and electrophysiologic evaluation
- individuals with systemic LVEF ≤35% and sustained VT or presumed arrhythmogenic syncope
- individuals with spontaneous hemodynamically stable sustained VT who have undergone hemodynamic and electrophysiologic evaluation
- individuals with a single or systemic right ventricular ejection fraction less than or equal to 35%, particularly in the presence of additional risk factors such as VT, arrhythmic syncope, or severe systemic AV valve insufficiency.

Click Here to Return to the Main TOC

Indications for Cardiac Resynchronization Therapy (CRT-D) Implantation (CRID-5)

CID.CRT.005.A
v2.0.2026

Procedures included

CPT® 33224, 33225, 33208, 33229, 33249, 33264

Ischemic Cardiomyopathy (CRID-5.1)

CRT-D implantation is medically necessary for the treatment of ischemic cardiomyopathy when LVEF is less than or equal to 35% after greater than or equal to 3 month **OMT** with **any** of the following conditions:

- Sinus Rhythm with LBBB and **both** of the following:
  - QRS from 120 msec to 149 msec
  - NYHA Functional Class II, III, or ambulatory IV
- Sinus Rhythm with LBBB and **both** of the following:
  - QRS greater than or equal to 150 msec
  - NYHA functional class I, II, III, or ambulatory IV
- Sinus rhythm with non-LBBB and **both** of the following:
  - QRS greater than or equal to 150 msec
  - NYHA functional class III, or ambulatory IV
- Persistent or permanent atrial fibrillation and LBBB with QRS greater than or equal to 150 msec

CRT-P is considered medically necessary when all of the requirements of CRT-D have been met and the individual in consultation with the providing physician declines the ICD function.

Non-ischemic Cardiomyopathy (CRID-5.3)

CRT-D is medically necessary for the treatment of non-ischemic cardiomyopathy when LVEF is less than or equal to 35% after greater than or equal to 3 months of **OMT** with **any** of the following conditions:

- Sinus rhythm with LBBB and **both** of the following:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - QRS 120 msec to 149 msec
  - NYHA Functional Class II, III, or ambulatory IV
- Sinus rhythm with LBBB and **both** of the following:
  - QRS greater than or equal to 150 msec
  - NYHA Functional Class I, II, III, or ambulatory IV
- Sinus rhythm with Non-LBBB and **both** of the following:
  - QRS greater than or equal to 150 msec
  - NYHA Functional class III, or ambulatory class IV
- Persistent or Permanent atrial fibrillation and **both** of the following:
  - QRS greater than or equal to 150 msec
  - LBBB

CRT-P is considered medically necessary when all of the requirements of CRT-D have been met and the individual in consultation with the providing physician declines the ICD function.

Current or Anticipated RV Pacing with an Indication for an ICD (CRID-5.6)

CRT-D implantation is considered medically necessary for treatment of individuals who meet **all** of the following conditions:

- Current or anticipated RV pacing over 40%
- LVEF less than or equal to 35% after greater than or equal to 3 months of **OMT**
- NYHA Functional Class I, II, III, or ambulatory IV

CRT-P is considered medically necessary when all of the requirements of CRT-D have been met and the individual in consultation with the providing physician declines the ICD function.

Indications for upgrade to CRT-D (CRID-5.7)

Upgrade to CRT-D is medically necessary in individuals who have an implanted non-CRT-D ICD when **either** of the following conditions are documented:

- LVEF greater than or equal to 50% prior to ICD implant and **both** of the following are documented:
  - RV pacing burden greater than or equal to 40%
  - **One** of the following changes has occurred after implantation of non-CRT ICD:
    - Decline in LVEF greater than or equal to 10%
    - New or worsening heart failure symptoms (NYHA Class II or III)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- LV ejection fraction less than or equal to 35% after greater than or equal to 3 months of **OMT** and **both** of the following are documented:
  - New or worsening symptomatic heart failure (NYHA functional Class II, III, or ambulatory class IV) following implantation of a non-CRT pacemaker or cardioverter-defibrillator (ICD)
  - Ventricular pacing greater than or equal to 40%

CRT-P is considered medically necessary in an individual with a non CRT pacemaker when all of the other requirements of CRT-D have been met and the individual in consultation with the providing physician declines the ICD function.

Indications for CRT-P (CRID-5.8)

Procedures included

CPT® 33224, 33225, 33208, 33229

CRT-P is medically necessary for any of the following:

- High grade AV block and NYHA Class I, II or III Congestive Heart Failure:
  - Initial CRT-P implantation is medically necessary in individuals who have **all** of the following:
    - LV ejection fraction less than 50%
    - NYHA Class I, II, or III heart failure
    - High grade AV block, including AV nodal ablation, requiring more than 40% ventricular pacing CRT-P
- Pacing-induced cardiomyopathy
  - Upgrade from non-CRT pacemaker to CRT-P is medically necessary in individuals who have **all** of the following:
    - LVEF greater than or equal to 50% prior to implantation of non-CRT pacemaker
    - Right ventricular pacing burden greater than or equal to 40%
    - One of the following occurring after implantation of non-CRT pacemaker:
      - Decline in LVEF greater than or equal to 10%
      - New or worsening heart failure symptoms NYHA Class II or III
- See also **Indications for Cardiac Resynchronization Therapy (CRT)-D Implantation** for individuals who have met requirements for CRT-D, but decline the ICD function

Indications for conduction system pacing

His bundle pacing or left bundle branch area pacing (CPT® 33207 or CPT® 33208) is considered medically necessary when **Indications for CRT)** are met and one of the following applies:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- LV lead placement was attempted and was unsuccessful or suboptimal
- His bundle pacing or left bundle branch area pacing is planned in place of biventricular pacing

CRT Implantation - Non-indications (CRID-5.9)

Ischemic cardiomyopathy

CRT-D or CRT-P implantation is **not** medically necessary in individuals with ischemic cardiomyopathy who have had a myocardial infarction within the past 40 days or who have had coronary revascularization within the past 90 days **unless** a separate indication for permanent pacemaker or ICD implantation exists (thus preventing a likely repeat procedure for an upgraded device in the near future)

Reversible causes of cardiomyopathy

CRT-D implantation is **not** medically necessary in the setting of a reversible cardiomyopathy such as: toxic, metabolic, or tachycardia induced cardiomyopathy

Note: Once the reversible aberration is corrected, clinical reassessment is indicated

Wireless cardiac resynchronization - Criteria (CRID-5.10)

- Permanent LV leadless pacemakers (CPT® 0515T) are implanted directly in the left ventricle for synchronization with RV leads in the setting of cardiac resynchronization therapy. At this time, they are considered experimental, investigational, or unproven.

Evidence Discussion CRT

Evidence Discussion

Cardiac Resynchronization Pacing Therapy (CRT-P)

Asynchrony of electrical activation of different portions of the ventricles results in dyssynchrony of mechanical contraction leading to decreased efficiency of pump function. The cardiac resynchronization pacing device synchronizes electrical activation through a right ventricular lead and a lead inserted into a branch of the coronary venous system for left ventricular activation. Clinical decision-making for cardiac resynchronization pacing therapy includes consideration of an individual's risk of worsening symptomatic heart failure and the anticipated likelihood of favorable clinical response to cardiac resynchronization therapy balanced against short-term procedural risks (e.g., cardiac tamponade and contrast-mediated acute kidney injury) as well as

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

long-term device-related risks (e.g., thrombosis and infection). Randomized controlled clinical trials and systematic reviews of these trials provide valuable information to guide optimal selection of candidates for cardiac resynchronization pacing therapy. For instance, the benefit-risk assessment for cardiac resynchronization pacing therapy is favorable for individuals with left ventricular ejection fraction less than 50% who require frequent ventricular pacing greater than 40% of the time. Conversely, the benefit-risk assessment for cardiac resynchronization pacing therapy is NOT favorable for individuals who have better left ventricular ejection fraction or who do not require ventricular pacing or require ventricular pacing only infrequently. Indications for cardiac resynchronization pacing therapy are based on well-established clinical medical specialty organization evidence-based guideline recommendations and Appropriate Use Criteria.

Cardiac Devices for Other Conditions

CID.OD.011.A
v2.0.2026

Wireless pulmonary artery pressure sensor - Criteria (CRID-13)

Codes addressed

Description	CPT®
Transcatheter implantation of wireless pulmonary artery pressure sensor for long-term hemodynamic monitoring, including deployment and calibration of the sensor, right heart catheterization, selective pulmonary catheterization, radiological supervision and interpretation, and pulmonary artery angiography, when performed	33289

Indications

Although FDA approved, the wireless pulmonary artery pressure sensor device (e.g., CardioMEMS™ HF System) has yet to be incorporated into the standard of care and is considered experimental, investigational, or unproven at this time.

Evidence Discussion

Wireless Pulmonary Artery Pressure Sensor devices (CPT® 33289) such as CardioMEMS™ HF System, are implanted into a branch of the pulmonary artery during right heart catheterization and require a specialized delivery system. These devices monitor constant pulmonary artery pressures over time, utilizing the concept that as pulmonary artery pressures increase, outpatient medical therapy can be adjusted. This can potentially reduce inpatient admissions and treatment.

- Although FDA approved, these devices have yet to be incorporated into the standard of care and remain investigational and experimental at this time.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Wireless Left Atrial Pressure Sensor (CID-14)

Codes included

Description	CPT®
Transcatheter implantation of wireless left atrial pressure sensor for long-term left atrial pressure monitoring, including sensor calibration and deployment, right heart catheterization, transseptal puncture, imaging guidance, and radiological supervision and interpretation	0933T

Indications

Further studies are needed to evaluate the safety, clinical efficacy, and long-term stability of the wireless left atrial pressure sensor device. Wireless left atrial pressure sensor is considered experimental, investigational, or unproven at this time.

Evidence Discussion

Wireless left atrial pressure sensor (e.g., V-LAP™ system) implantation is performed percutaneously via femoral vein access and trans-atrial septal approach. It is proposed that the availability of hemodynamic parameters might allow clinicians to tailor heart failure treatment.

Cardiac Contractility Modulation (CRID-15)

Codes included

Description	CPT®
Insertion or replacement of permanent cardiac contractility modulation system, including contractility evaluation when performed, and programming of sensing and therapeutic parameters; pulse generator with transvenous electrodes	0408T
Insertion of permanent cardiac contractility modulation-defibrillation system component(s), including fluoroscopic guidance, and evaluation and programming of sensing and therapeutic parameters; pulse generator and dual transvenous electrodes/leads (pacing and defibrillation)	0915T

Proprietary Information of UnitedHealthcare.

Cardiac contractility modulation (CCM)

CPT® 0408T

Currently, there is insufficient evidence of benefit of cardiac contractility modulation (CCM) on clinical outcomes. CCM devices (e.g.,Optimizer Smart®) are considered experimental, investigational, or unproven at this time.

Combined Cardiac Contractility Modulation and Implantable Cardioverter-Defibrillator Device (CCM-D)

CPT® 0915T

Currently there is insufficient evidence of safety, efficacy, and benefit of combined cardiac contractility modulation and implantable cardioverter defibrillator devices (CCM-D) devices on clinical outcomes. CCM-D devices (e.g., Optimizer® Integra™ CCM-D System) are considered experimental, investigational, or unproven at this time.

Evidence Discussion

Cardiac contractility modulation (CCM) delivers electrical signals during the ventricular absolute refractory period. This does not generate an action potential or mechanical contraction but is proposed to enhance ventricular contractile strength. CCM has been proposed as a potential treatment option for individuals with symptomatic heart failure with reduced left ventricular ejection fraction who are not candidates for cardiac resynchronization therapy.

CCM has previously been used along with a separate implantable cardioverter-defibrillator device (ICD). The Combined Cardiac Contractility Modulation and Implantable Cardioverter-Defibrillator Device (CCM-D) combines CCM and ICD functionality in one device.

Baroreflex Activation Therapy (CRID-16)

Description	CPT®
Initial open implantation of baroreflex activation therapy (BAT) modulation system, including lead placement onto the carotid sinus, lead tunneling, connection to a pulse generator placed in a distant subcutaneous pocket (ie, total system), and intraoperative interrogation and programming	64654

Currently there is insufficient evidence of benefit of baroreflex activation therapy on clinical outcomes. Carotid baroreflex activation therapy (e.g., Barostim™ device) is considered experimental, investigational, or unproven at this time.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Evidence Discussion

Carotid baroreflex activation therapy (e.g., Barostim™ device) uses a subcutaneously implanted pulse generator and electrode system to deliver electrical impulses to the carotid artery baroreceptors. Carotid baroreflex activation is aimed at decreasing sympathetic activity and increasing parasympathetic activity and has been proposed as a potential treatment option for individuals with symptomatic heart failure with reduced left ventricular ejection fraction.

General Guidelines (CH-1.0)

CH.GG.0001.0.A

v1.0.2026

- A pertinent clinical evaluation since the onset or change in symptoms is required prior to considering advanced imaging.
  - A pertinent clinical evaluation should include the following:
    - a detailed history and physical examination
    - appropriate laboratory studies and basic imaging, such as plain radiography or ultrasound
      - A chest x-ray since the onset or change in symptoms that has been over read by a radiologist would be performed in many of these cases prior to considering advanced imaging.
        - Identify and compare with previous chest films to determine presence and stability.
  - For an established individual a meaningful technological contact (telehealth visit, telephone call, electronic mail or messaging) since the onset or change in symptoms can serve as a pertinent clinical evaluation.

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

General Guidelines – Chest X-Ray (CH-1.1)

CH.GG.0001.1.A
v1.0.2026

- Chest x-ray can help identify previously unidentified disease and direct proper advanced imaging for such conditions as:
  - mediastinal lymphadenopathy (See **Mediastinal Lymphadenopathy (CH-2.3)**)
  - cough (See **Cough (CH-3.1)**)
  - non-cardiac chest pain (See **Non-Cardiac Chest Pain - Imaging (CH-4.1)**)
  - dyspnea (See **Dyspnea/Shortness of Breath (CH-5.1)**)
  - suspected post endobronchial valve complication (See **Post Endobronchial Valve (EBV) Placement (CH-5.3)**)
  - hemoptysis (See **Hemoptysis (CH-6.1)**)
  - bronchitis (See **Bronchitis (CH-8.1)**)
  - asbestos exposure (See **Asbestos Exposure (CH-9.1)**)
  - chronic obstructive pulmonary disease (See **COPD (CH-10.1)**)
  - e-cigarette or vaping product use-associated lung injury (See **E-cigarette, or Vaping, Product-Use Associated Lung Injury (EVALI) (CH-11.2)**)
  - pleural effusion (See **Pleural Effusion (CH-18.1)**)
  - pneumothorax or hemothorax (See **Pneumothorax/Hemothorax (CH-19.1)**)
  - pneumomediastinum (See **Pneumomediastinum; Subcutaneous Emphysema (CH-19.2)**)
  - fractured ribs, sternum, or clavicle (See **Chest Trauma (CH-21.1)**)
  - chest wall mass (See **Chest Wall Mass (CH-22.1)**)
  - acute and chronic infections (See **Pneumonia and Coronavirus Disease 2019 (COVID-19) (CH-13)** and **Other Chest Infections (CH-14)**)
  - malignancies
- Exceptions to preliminary chest x-ray may include such conditions as:
  - supraclavicular lymphadenopathy (See **Supraclavicular Region (CH-2.1)**)
  - axillary lymphadenopathy (See **Axillary Lymphadenopathy (and Mass) (CH-2.2)**)
  - costochondritis (See **Costochondritis/Other Musculoskeletal Chest Wall Syndrome (CH-4.2)**)
  - pre-operative assessment (See **Pre-Operative Assessment CH-5.2)**)
  - known bronchiectasis (See **Bronchiectasis (CH-7.1)**)
  - cystic fibrosis (See **Adult Cystic Fibrosis (CH-7.2)**)
  - suspected interstitial lung disease (See **Interstitial Lung Disease (ILD)/Diffuse Lung Disease (DLD) (CH-11.1)**)

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- positive PPD or tuberculosis (See **Other Chest Infections (CH-14)**)
- sarcoidosis (See **Sarcoid (CH-15.1)**)
- pulmonary nodules (See **Solitary Pulmonary Nodule (SPN) (CH-16)** and **Pleural-Based Nodules and Other Abnormalities (CH-17.1)**)
- mediastinal mass (See **Mediastinal Mass (CH-20.1)**)
- pectus excavatum and carinatum (See **Pectus Excavatum and Carinatum (CH-23.1)**)
- pulmonary arteriovenous fistula (See **Pulmonary AVM (CH-24.1)**)
- pulmonary embolism (See **Pulmonary Embolism (CH-25.1)**)
- elevated hemidiaphragm (See **Elevated Hemidiaphragm (CH-30.1)**)
- pre- or post-lung transplant (See **Lung Transplantation (CH-32)**)
- lung cancer screening (See **Lung Cancer Screening (CH-33)**)

Proprietary Information of UnitedHealthcare.

General Guidelines – Chest Ultrasound (CH-1.2)

CH.GG.0001.2.A

v1.0.2026

- Chest ultrasound (CPT® 76604) includes transverse, longitudinal, and oblique images of the chest wall with measurements of chest wall thickness, and also includes imaging of the mediastinum. It may be helpful in identifying pleural effusions (See **Pleural Effusion (CH-18)**).
  - Chest ultrasound:
    - CPT® 76604
  - Breast ultrasound:
    - CPT® 76641: unilateral, complete
    - CPT® 76642: unilateral, limited
    - CPT® 76641 and CPT® 76642 be reported only once per breast, per imaging session
  - Axillary ultrasound:
    - CPT® 76882 (unilateral); if bilateral, can be reported as CPT® 76882 x 2

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

General Guidelines – CT Chest (CH-1.3)

CH.GG.0001.3.A
v1.0.2026

- Intrathoracic abnormalities as covered in these guidelines found on chest x-ray, fluoroscopy, CT Abdomen, or other imaging modalities can be further evaluated with CT Chest with contrast (CPT® 71260).
- CT Chest without contrast (CPT® 71250) can be used for the following:
  - individual has contraindication to contrast
  - follow-up of pulmonary nodule(s)
  - High Resolution CT (HRCT)
- For low-dose CT Chest (CPT® 71271 OR CPT® 71250): See **Lung Cancer Screening (CH-33).**
- CT Chest without and with contrast (CPT® 71270) does not add significant diagnostic information above and beyond that provided by CT Chest with contrast, unless a question regarding calcification, most often within a lung nodule, needs to be resolved.

CT Chest Coding Notes:

- High-resolution CT Chest should be reported only with an appropriate code from the set CPT® 71250-CPT® 71270.
  - No additional CPT® codes should be reported for the “high-resolution” portion of the scan. The “high-resolution” involves additional slices which are not separately billable.
- Low-dose CT chest does not have a specific, separate CPT® code associated with it. It should be reported with the standard CT chest CPT code (CPT® 71250).
  - An exception to this is the low-dose CT used specifically for the annual lung cancer screening scans, for which CPT® 71271 is used.

Proprietary Information of UnitedHealthcare.

General Guidelines – CTA Chest (CPT® 71275) (CH-1.4)

CH.GG.0001.4.A
v1.0.2026

- CTA Chest (CPT® 71275) is medically necessary for:
  - non-cardiac chest pain (See **Non-Cardiac Chest Pain - Imaging (CH-4.1)**)
  - hemoptysis (See **Hemoptysis (CH-6.1)**)
  - pulmonary arteriovenous fistula (See **Pulmonary AVM (CH-24.1)**)
  - pulmonary embolism (See **Pulmonary Embolism (CH-25.1)**)
  - pre-lung transplantation (See **Pre-Transplant Imaging Studies (CH-32.1)**)
  - prior to minimally invasive or robotic surgery (See **Transcatheter Aortic Valve Replacement (TAVR) (CD-4.8)** in the Cardiac Imaging Guidelines)

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

General Guidelines – MRI Chest without and with Contrast (CPT® 71552) (CH-1.5)

CH.GG.0001.5.A
v1.0.2026

- Indications for MRI Chest are infrequent and may relate to concerns about CT contrast such as renal insufficiency or contrast allergy. MRI is medically necessary for:
  - Clarification of equivocal findings on previous imaging studies (often in the thymic mediastinal region).
    - Certain conditions include:
      - mediastinal lymphadenopathy (See **Mediastinal Lymphadenopathy (CH-2.3)**)
      - chest wall mass (See **Chest Wall Mass (CH-22.1)**)
      - mediastinal mass (See **Mediastinal Mass (CH-20.1)**)
      - chest muscle tendon injuries (See **Muscle/Tendon Unit Injuries/Diseases (MS-11.0)** in the Musculoskeletal Imaging Guidelines)
      - pectoralis tendon rupture (See **Muscle/Tendon Unit Injuries/Diseases (MS-11.0)** in the Musculoskeletal Imaging Guidelines)
      - brachial plexopathy (See **Brachial Plexus (PN-4.1)** in the Peripheral Nerve Disorders Imaging Guidelines)
      - thymoma (See **Thymoma and Thymic Carcinoma - Suspected/Diagnosis (ONC-10.5)** in the Oncology Imaging Guidelines)

General Guidelines – Nuclear Medicine (CH-1.6)

CH.GG.0001.6.A
v1.0.2026

CPT	Description
78580	Pulmonary perfusion imaging (eg, particulate)
78582	Pulmonary ventilation (eg, aerosol or gas) and perfusion imaging
78597	Quantitative differential pulmonary perfusion, including imaging when performed
78598	Quantitative differential pulmonary perfusion and ventilation (e.g., aerosol or gas), including imaging when performed

- For pulmonary perfusion imaging (eg, particulate) (CPT® 78580) and pulmonary ventilation (eg, aerosol or gas) and perfusion imaging (CPT® 78582): See **Pulmonary Embolism (CH-25.1).**
- For quantitative differential pulmonary perfusion, including imaging when performed (CPT® 78597) and quantitative differential pulmonary perfusion and ventilation (e.g., aerosol or gas), including imaging when performed (CPT® 78598): See **Pre-Operative Assessment (CH-5.2).**

Navigational Bronchoscopy and Biopsy (CH-1.7)

CH.GG.0001.7.A
v1.0.2026

- CPT® 76497 (Unlisted CT procedure) if:
  - A CT Chest has been performed within the last 6 weeks and study is needed for navigational bronchoscopy.
- CT Chest without contrast (CPT® 71250) if:
  - Previous diagnostic scan was ≥6 weeks ago and study is needed for navigational bronchoscopy.
- Bronchoscopy with computer-assisted, image-guided navigation, includes three-dimensional reconstruction. Do not report in conjunction with 3-D rendering CPT codes (CPT® 76376) or (CPT® 76377).
- Core needle biopsy (CPT® 32408) for:
  - Biopsy of the lung or mediastinum to diagnose malignancy.
- For robotic-assisted lung resection, see **Pre-Operative Assessment (CH-5.2)**.

Background and Supporting Information

- Navigational bronchoscopy: This is a form of guided bronchoscopy. A special sensor inside a bronchoscopy is used to navigate to the desired location within the lung. Computer software generates a virtual bronchial tree which provides a road map to the target lesion. A thin-cut CT Chest with optimized reconstruction parameters is required to generate the virtual map of the lungs. A previous CT Chest may not be usable for navigation if it was not formatted correctly, even if done just a few days prior.
- Names for navigational bronchoscopy systems can include:
  - superDimension or super-D
  - Spin Thoracic Navigation System
  - Archimedes
  - Monarch Platform - robotic
  - Ion - endoluminal robotic bronchoscopy platform
- The diagnostic accuracy of navigational bronchoscopy is 70.9-79%. It has an excellent safety profile, with an adverse event rate (e.g., pneumothorax) of 3.3-5.6%.
- Cone-Beam CT, (CBCT) is a newer technique that helps locate the nodule in real time. Studies have shown comparable results and diagnostic yields to other guided bronchoscopy strategies. CBCT combined with other navigational techniques often reaches a higher navigational success rate and diagnostic rate. However, a recent

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

study found no statistically significant differences in diagnostic sensitivity, specificity, and accuracy between those who received CBCT and other methods. Additionally, CBCT can expose the individual and operator to radiation through the repeated acquisition of images. The mean radiation dose was determined to be 48.4 Gy cm^2 per case; this excessive and unnecessary radiation can cause radioactive damage to the individual and the operator. Another study concluded that, "Additional studies are warranted to confirm the safety and efficacy of this technique". Efforts are required to improve diagnostic accuracy and standardized practices before CBCT can be considered mainstream. Large-scale randomized controlled trials that compare CBCT with other navigational techniques are necessary to determine the most optimal navigational strategy, clinical criteria for CBCT usage, and the best way to diagnose peripheral pulmonary lesions.

Supraclavicular Region (CH-2.1)

CH.LA.0002.1.A
v1.0.2026

- Ultrasound (CPT® 76536) is the initial study for palpable or suspected lymphadenopathy.
  - Allows simultaneous ultrasound-guided core needle biopsy (CPT® 76942)
  - CT Neck with contrast (CPT® 70491) or CT Chest with contrast (CPT® 71260) if ultrasound is indeterminate
    - See **General Guidelines (Neck-1.0)** in the Neck Imaging Guidelines

Evidence Discussion

For suspected or palpable supraclavicular lymphadenopathy, ultrasound (US) has an excellent sensitivity rate, up to 100% for the detection of metastases. CT Neck had a lower sensitivity rate of 83% for the same lesion.[6] Ultrasound avoids the ionizing radiation exposure of CT, is readily available, and allows for the use of US-guided fine-needle aspiration cytology for diagnosis.

Axillary Lymphadenopathy (and Mass) (CH-2.2)

CH.LA.0002.2.A

v1.0.2026

- There is no evidence-based support for advanced imaging of clinically evidenced axillary lymphadenopathy prior to a biopsy. If axillary node biopsy reveals benign findings, advanced imaging is not medically necessary. If axillary node biopsy reveals findings concerning for malignancy, pathology results will determine the need for further advanced imaging. See **Carcinoma of Unknown Primary Site (ONC-31.7)** in the Oncology Imaging Guidelines for imaging recommendations for carcinoma found in an axillary lymph node.
- Localized axillary lymphadenopathy:
  - Axillary US (CPT® 76882)
    - Initial evaluation of any axillary mass or enlarged node
  - Search for adjacent hand or arm injury or infection, and
  - 3-4 week observation if benign clinical picture (for ipsilateral COVID vaccination-related adenopathy, observation for 12 or more weeks is recommended). Follow-up imaging with ultrasound is medically necessary if there is a significant risk of metastatic adenopathy (e.g., breast, head and neck, upper extremity/trunk melanoma or lymphoma)
    - If axillary adenopathy is unchanged, then consider additional follow up 6 months after initial presentation.
  - Ultrasound directed core needle biopsy or surgical excisional biopsy of the most abnormal lymph node if:
    - Condition persists.
    - Malignancy is suspected.
  - Surgical excisional biopsy if core needle biopsy results are non-diagnostic.
  - Advanced imaging is not medically necessary.
- Generalized axillary lymphadenopathy:
  - Axillary US (CPT® 76882)
    - Initial evaluation of any axillary mass or enlarged node
  - Ultrasound directed core needle biopsy or surgical excisional biopsy of the most abnormal lymph node if condition persists, if malignancy is suspected, or surgical excisional biopsy if core needle biopsy results are non-diagnostic.
  - Diagnostic work-up, including serological tests, for systemic diseases
  - Advanced imaging is not medically necessary.
  - See **Non-Hodgkin Lymphomas (ONC-27)** in the Oncology Imaging Guidelines.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Occult primary cancer in axillary lymph node(s):
  - See **Metastatic Cancer, Carcinoma of Unknown Primary Site, and Other Types of Cancer (ONC-31)** in the Oncology Imaging Guidelines.
- For unexplained axillary lymphadenopathy in individuals with silicone breast implants, see **Breast Implant Evaluation (BR-5.2)**

Evidence Discussion

Initial evaluation of an axillary mass or axillary lymphadenopathy (LAN) should be ultrasound (US). US allows for real-time evaluation and immediate image-directed biopsy.[11] CT Chest is usually not appropriate in the evaluation of axillary LAN, especially in the female population with concern for breast cancer.[10]

Ultrasound is a very important initial imaging modality which is easy to obtain, universally available and portable, exposes individuals to no radiation, and is cost effective. It is also excellent in helping to determine next best advanced imaging study including appropriate protocol and contrast level. US not only provides excellent soft tissue resolution, but also provides characterization of cystic lesions (Bosniak classification) whether complex or simple to help guide follow up imaging interval or biopsy.

Background and Supporting Information

- Adenocarcinoma is the most common histology, with breast cancer seen most often; non-palpable breast cancer and axillary metastases accounts for less than 0.5% of all breast cancers. Carcinomas of the lung, thyroid, stomach, colon, rectum, and pancreas have the potential to spread to axillary lymph nodes, but these metastases are rarely the first manifestations of disease.
- COVID-19 vaccine-related unilateral axillary adenopathy has been well documented to occur in 12% of recipients after the first dose and up to 16% after the second dose. In some series the incidence has been as high as 53%. Adenopathy usually develops within the first few days after vaccination and lasts a mean of 10 days. However, 29% had lymphadenopathy which persisted >6 weeks. PET-CT can provide false positive results of unilateral axillary adenopathy up to 7-10 weeks post vaccination. Due to these concerns, in individuals with cancer history, it is recommended that the vaccination be provided in the contralateral arm, especially in case of unilateral breast cancer.
- The Society for Breast Imaging (SBI) recommends that for unilateral axillary adenopathy on screening exams who received a recent COVID-19 vaccination in the ipsilateral upper extremity, a follow up interval of 12 or more weeks is recommended. If axillary adenopathy persists after short term follow up, then consider lymph node sampling to exclude breast and non-breast malignancy. Imaging for urgent cancer related clinical indication should not be delayed in relationship to COVID vaccine timing. For routine surveillance, screening and similar non-urgent

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

indications, postponement of imaging for at least 6 weeks after vaccinations should be considered. However, the SBI no longer recommends delaying screening mammograms around COVID-19 vaccinations.

Mediastinal Lymphadenopathy (CH-2.3)

CH.LA.0002.3.A

v1.0.2026

- CT Chest with contrast (CPT® 71260) if mediastinal abnormalities are detected on a chest x-ray (over read by a radiologist), other non-dedicated advanced chest imaging, or clarification of mediastinal abnormalities on a non-contrast CT Chest.
  - If contrast cannot be tolerated due to allergy or renal dysfunction, MRI chest without and with contrast (CPT® 71552) OR MRI chest without contrast (CPT® 71550) is medically necessary.
  - Follow-up CT Chest (CPT® 71260) after 3-6 months if:
    - enlarged lymph nodes, ≥15 mm, are in the mediastinum with no other thoracic abnormalities; and
    - thereafter, stability or decreasing size, further advanced imaging is not medically necessary.
  - Further evaluations:
    - Lymph node biopsy (see methods below) is medically necessary for:
      - persistent or increasing lymphadenopathy on follow-up CT Chest; or
      - suspected malignancy.
      - See **Non-Hodgkin Lymphomas (ONC-27)** and/or **Hodgkin Lymphoma (ONC-28)** in the Oncology Imaging Guidelines for suspicion of Lymphoma.
- PET/CT (CPT® 78815) is medically necessary for enlarged lymph nodes, ≥15 mm with no explainable disease or increasing lymph node size on follow-up CT Chest

Evidence Discussion

- CT Chest is medically necessary for mediastinal abnormalities detected on chest x-ray or other non-dedicated advanced imaging. CT allows for further tissue characterization and can distinguish between calcium, macroscopic fat and water attenuation fluid.[1] CT has higher contrast resolution than plain chest radiography. CT does carry with it the risk of both iodinated contrast exposure and ionizing radiation exposure.
- Asymptomatic, incidental mediastinal lymph nodes less than 15mm (in the short axis) do not require follow up. Evison et al found that size was the greatest predictor of lymph node etiology with those less than 15mm always found to be reactive.[8]
- For mediastinal lymph nodes greater than or equal to 15mm, follow-up should be directed by suspected etiology. For those with low or no clinical suspicion for malignancy and no other thoracic abnormalities, follow up CT chest in 3-6 months is medically necessary.[8] If the lymph nodes have increased in size on follow-up imaging, PET/CT or tissue biopsy is medically necessary.[8]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- For those with no explainable disease and mediastinal lymph nodes greater than or equal to 15mm, PET/CT is medically necessary. However, PET/CT has well-documented false positive results in this setting given the overlap of increased FDG uptake in both oncologic and infection or inflammatory disease processes.[8]

Background and Supporting Information

- Incidentally detected lymph nodes <15mm (in short axis) in individuals with no other findings do not require further evaluation.
- Most benign nodes have smooth and well-defined borders, show uniform and homogeneous attenuation, and demonstrate a central fatty hilum.
- Explainable disease such as emphysema, interstitial lung disease, sarcoidosis, cardiac disease.
- Unexplained causes, consider lymphoma, undiagnosed metastatic disease, including testicular carcinoma in young male, and infection.
- Lymphadenopathy from neoplasms as well as from benign sources of inflammation can result in a positive PET scan. Therefore, the use of PET may not be helpful prior to histologic diagnosis.
- Less invasive methods of mediastinal biopsies are CT or ultrasound directed percutaneous biopsy, transbronchial biopsy, transbronchial biopsy using endobronchial ultrasound, and endoscopic ultrasound-guided FNA.
- More invasive and traditional methods are mediastinoscopy or thoracoscopy/ thoracotomy.

Cough (CH-3.1)

CH.CH.0003.1.A
v1.0.2026

- Initial evaluation should include a chest x-ray after the current episode of cough started or changed.
  - In addition all medications known to cause coughing (e.g., ACE inhibitors, Sitagliptin) should be discontinued.
- CT Chest (either with contrast [CPT® 71260] or without contrast [CPT® 71250]), if the initial chest x-ray is without abnormalities and all medications known to cause coughing have been discontinued, for the following:
  - Non-smoker cough after the following sequence for a total 3-week trial and investigation after ALL of the following:
    - Antihistamine and decongestant or intranasal glucocorticoid treatment.
    - Spirometry and/or pulmonary function tests (PFT's).
    - Empiric trial of corticosteroids (oral or inhaled) and/or leukotriene receptor antagonist (e.g., Montelukast).
    - Treatment of gastroesophageal reflux disease (GERD).
      - See **Sinus and Facial Imaging (HD-29.1)** in the Head Imaging Guidelines.
  - Current or past cigarette smokers with either:
    - new cough lasting greater than 2 weeks
    - changed chronic cough in worsening frequency or character
      - See **Hemoptysis (CH-6.1)**
  - See the relevant Chest Imaging Guideline section for advanced chest imaging to evaluate any abnormalities present on the initial chest x-ray.
  - For individuals with high suspicion for lung cancer despite normal chest x-ray:
    - See **Non-Small Cell Lung Cancer Suspected/Diagnosis (ONC-8.2)**
- CT Maxillofacial without contrast (CPT® 70486) or CT Sinus, limited without contrast (CPT® 76380) is medically necessary in those with suspicion of Upper Airway Cough Syndrome (UACS) in the following:
  - Clinical criteria for chronic rhinosinusitis (CRS) or acute/recurrent rhinosinusitis are met, as per **Sinus and Facial Imaging (HD 29.1)**; **OR** ALL of the following:
    - at least a one week trial of daily antihistamine/decongestant
    - initial evaluation with a chest x-ray and/or CT Chest after the current episode of cough started or changed
    - all medications known to cause cough have been discontinued

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Evidence Discussion

CT chest is not recommended routinely in people with a chronic cough, normal chest x-ray, and normal physical exam. There is concern regarding potential cancer risk from CT radiation exposure, especially in women and children.[7] For individuals with cough of unknown etiology or a chronic cough refractory to therapy, a CT chest may identify changes not seen on chest x-ray, such as interstitial lung disease or bronchiectasis.[7,9,12]

Current or former smokers with a new cough or change in chronic cough do not need a trial of therapy for UACS, asthma or GERD prior to a chest CT if an initial chest x-ray is abnormal or non-diagnostic.[3]

CT maxillofacial may be considered for suspected chronic rhinosinusitis (CRS) as the cause of chronic cough after clinical examination and chest x-ray if there is no response to empiric therapy or if the history and nasal endoscopy findings are concerning for CRS.[3,5,9]

Background and Supporting Information

- The resolution of cough usually will occur at a median time of 26 days of stopping use of the angiotensin-converting enzyme (ACE) inhibitor drug. Smoking cessation is “almost always effective” in resolving cough in smoker.
- Cough after URI (Upper Respiratory Infection) can typically last beyond 2-3 weeks.
- Objective evidence of classic asthmatic cough conventionally requires some evidence of variable airflow obstruction such as peak flow variability, or reversibility to bronchodilator of >12%-15%.
- In adults with chronic cough suspected to be due to reflux-cough syndrome, it is recommended that treatment include (1) diet modification to promote weight loss in overweight or obese individuals; (2) head of bed elevation and avoiding meals within 3 hours of bedtime; and (3) in individuals who report heartburn or regurgitation, PPI's, H-2 receptor antagonists, alginate or antacid therapy sufficient to control these symptoms.
- When cough remains refractory to treatment, high-resolution CT scanning of the thorax is recommended to rule out parenchymal lung disease that is not visible on plain chest x-ray.

Cough Health Equity Considerations

Health Equity Considerations for Cough

- Chronic cough is more prevalent in older adults. Younger adults with chronic cough are more likely to be men, and older adults are more likely to be women.

Non-Cardiac Chest Pain – Imaging (CH-4.1)

CH.CP.0004.1.A
v1.0.2026

- Initial evaluation should include a chest x-ray.
  - CT Chest with contrast (CPT® 71260) or CTA Chest (CPT® 71275) if x-ray is abnormal. See **Pneumonia (CH-13.1)**
- Sub-Sternal Non-Cardiac Chest Pain:
  - If x-ray is normal and the chest pain is substernal, the individual should undergo evaluation of other possible causes of pain prior to advanced imaging (CT Chest with contrast or CTA Chest) including:
    - Cardiac evaluation (See General Guidelines (CD-1) in the Cardiac Imaging Guidelines)
    - GI treatment with any ONE of the following:
      - Trial of anti-reflux medication, or pH probe, or esophageal manometry or
      - Barium swallow or endoscopy
    - Pulmonary Function Test (PFT's) in those with known or suspected respiratory disease
  - CT Chest with contrast (CPT® 71260) if persistent:
    - The initial chest x-ray reveals no abnormalities with known Sickle cell disease
- Non-Cardiac Chest Pain, other than Sub-Sternal:
  - If x-ray is normal and the chest pain is in a location other than substernal:
    - CT Chest with (CPT® 71260) or without (CPT® 71250) contrast and/or bone scan for:
      - known or suspected malignancy, including individuals with chest pain associated with cough and weight loss
    - CT Chest with (CPT® 71260) or without (CPT® 71250) contrast for:
      - suspected infectious or inflammatory condition
      - history of prior chest intervention (surgery, Radiation Therapy)
    - MRI Chest without and with contrast (CPT® 71552) for:
      - necrotizing fasciitis
      - surgical planning prior to debridement procedure
  - For suspected migration of implantable contraceptive devices, see Implantable Contraceptive Devices (PV-10.3)

Evidence Discussion

It is important to rule out potentially life-threatening causes of acute chest pain, such as an acute coronary syndrome, aortic dissection, and pulmonary embolus. These topics are discussed in other guideline summaries (CD 1.0, CD 1.4, PVD 6.2 and PVD 6.3, CH 25.1). A specialized imaging protocol called the "triple rule-out" is sometimes used to evaluate the pulmonary arteries, aorta and coronary arteries. However, it is associated with higher non-diagnostic imaging quality, radiation and contrast doses.[8] The population for which it may be useful is unknown. It is yet to be proven useful in large clinical trials, and its appropriate use needs to be further defined.[8,9,10]

An evaluation for the cause of non-cardiac "angina-like" chest pain should be done if it persists or recurs despite a negative stress test or anatomic cardiac evaluation, or a low risk designation by a clinical decision pathway.[11] The differential diagnosis of non-cardiac chest pain is broad. The most common causes in a primary care setting are chest wall pain, reflux esophagitis, and costochondritis.[6] Respiratory causes include pneumonia, pleuritis , and pneumothorax. People with COPD or acute asthma exacerbations may experience chest pain.[5,12] A thorough history and physical exam are important to help narrow the differential diagnosis and direct imaging. Musculoskeletal causes are usually diagnosed based on history and physical exam (point tenderness, reproducibility with palpation) without the need for diagnostic imaging. Most individuals should have an ECG and chest x-ray (CR).[11] CR is rapid, non-invasive and is medically necessary in the initial evaluation of acute non-specific chest pain with a low probability of coronary artery disease (CAD).[1,11] In individuals without evidence of cardiac or pulmonary disease, evaluation for a GI cause is reasonable. An empiric trial of acid suppression may be merited. If this is ineffective or there are alarm symptoms, an EGD, pH probe and/or motility study should be considered.[11,13,14]

Individuals with sickle cell disease and acute chest pain should have a CR initially.[11] Acute chest syndrome is defined by a new infiltrate on CR with fever and/or respiratory symptoms. In the presence of unexplained hypoxemia and an unremarkable CR, CT chest may be obtained to evaluate the pulmonary vasculature and lung parenchyma.[15]

CR is medically necessary for non-traumatic chest wall pain and no history of malignancy to evaluate for a specific etiology, such as rib fracture, pneumonia, or pneumothorax.[4,17] Following a normal CR, CT chest is medically necessary to evaluate chest pain in the setting of known or suspected malignancy, suspected infectious or inflammatory condition, or a history of prior chest intervention.[4] CT is more sensitive than CR for characterizing chest wall neoplasms, chest wall infections, and subtle osseous and soft tissue lesions. Chest MRI is useful if there is a high suspicion for necrotizing fasciitis and for surgical planning prior to debridement.[4]

Costochondritis/Other Musculoskeletal Chest Wall Syndrome (CH-4.2)

CH.CP.0004.2.A
v1.0.2026

- Initial evaluation should include a chest x-ray.
- CT chest (CPT® 71250 or CPT® 71260) is medically necessary for inconclusive or nondiagnostic findings on chest x-ray AND one of the following:
  - concern for infectious or neoplastic processes
  - persistent symptoms >3 weeks (despite treatment)
- For MRI requests, see the applicable section:
  - **Infection (MS-9.0)**
  - **Muscle and Tendon Injuries (MS-11)**
  - **Joint Instability and Dysfunction (MS-30)**
  - **Chest Wall Mass (CH-22.1)**
- For slipping rib syndrome, dynamic chest ultrasound (CPT® 76604) is medically necessary.
  - CT chest (CPT® 71250 or CPT® 71260) is medically necessary for pre-surgical planning
- For other conditions not mentioned, see **Non-Cardiac Chest Pain - Imaging (CH-4.1)**

Evidence Discussion

Costochondritis is a common cause of chest wall pain in adults presenting to the emergency department and physician's office.[3,16] It is defined as inflammation of costochondral junctions of ribs or costosternal joints, usually at multiple levels and without any swelling or induration.[3] It is a self-limited condition. The diagnosis is largely based on history and physical examination, which reproduces pain on palpation of the chest wall. Upper body movement, deep breathing, and exertional activities often exacerbate the pain.[3,16] Tietze syndrome presents similarly to costochondritis but includes visible edema at the involved joint(s), typically is unilateral involving the second rib, and is often incited by infection or trauma.[16]

There are no laboratory tests or imaging tests findings specifically for the diagnosis of costochondritis.[22] If an individual relates a history of dyspnea or chest wall trauma, a chest radiograph or rib series is medically necessary.[4,16] Chest radiographs can help identify potential sources of previously undifferentiated chest pain such as pneumothorax, pneumomediastinum, fractured ribs, acute and chronic infections, pneumonia, lung mass, and malignancies.[1] A large observational study found that 91%

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

of individuals with new-onset costochondritis had resolution of pain after three weeks of treatment with rest and nonsteroidal anti-inflammatory drugs.[18] Thus, chest CT should be reserved for individuals who have persistent symptoms greater than 3-4 weeks, or where there is high suspicion for infection or neoplastic processes.[3] Scintigraphy has been studied to determine its usefulness to diagnose costochondritis, but it is not specific for the diagnosis.[3]

Most treatment recommendations are conservative in nature and have been traditionally accepted, perhaps because of the self-limited nature of the condition.[3,16]

Recalcitrant cases may respond to corticosteroid injections.[16]

Background and Supporting Information

- Chest x-ray could identify pneumothorax, pneumomediastinum, fractured ribs, acute and chronic infections, and malignancies.
- Costochondritis can be readily diagnosed with palpation tenderness and/or hooking maneuver and imaging is non-specific.
- Chest CT, chest MRI, and bone scans are not helpful for the diagnosis of slipping rib syndrome. However, they may be helpful in delineating rib anatomy, which would aid in surgical planning.
- Dynamic chest ultrasound accurately diagnoses slipping rib syndrome in 89% of cases and has a 100% negative predictive value.
- Intercostal nerve blocks could be used for diagnostic and therapeutic purposes.

Dyspnea/Shortness of Breath (CH-5.1)

CH.SB.0005.1.A
v1.0.2026

- Initial evaluation should include a chest x-ray since onset or change in symptoms.
  - CT Chest without contrast (CPT® 71250) OR CT Chest with contrast (CPT® 71260) if x-ray is abnormal.
  - CT Chest without contrast (CPT® 71250, including HRCT), or CT Chest with contrast (CPT® 71260) if the initial chest x-ray is indeterminate and the following evaluations have been conducted, since onset or change in symptoms, and are indeterminate:
    - ECG, echocardiogram or stress testing, and
    - Pulse oximetry and pulmonary function studies (PFT's)
- If pulmonary embolus (PE) is suspected, See **Pulmonary Embolism (PE) (CH-25)**.
- For persistent dyspnea post-COVID-19 infection, see Coronavirus Disease 2019 (COVID-19) (CH-13.2).

Evidence Discussion

There is no standard approach for the evaluation of chronic dyspnea, and data that test diagnostic algorithms against standard clinical care are limited; however, clinical practice algorithms have been proposed and found to be effective.[13-16] If the diagnosis is not evident after a history and physical exam, initial diagnostic testing with pulse oximetry, spirometry, chest radiography (CR), ECG, and labs is recommended.[14,15,17] While the individual utility of these tests varies for a specific diagnosis, they are commonly available and easy to perform.[17]

Spirometry can identify obstructive lung disease or suggest restrictive lung disease. The flow-volume loop may suggest intra- or extra-thoracic airway obstruction. Some authors recommend full pulmonary function tests as part of the initial investigation, while others consider spirometry an appropriate initial test.[13,15] Diagnostic accuracy is improved when spirometry is done in addition to a clinical assessment.[17]

ECG has a high negative predictive value for cardiac disease but low specificity. Thus, further testing such as echo is often necessary.[17] The recommended timing of echocardiography differs between algorithms but echo is an important test for cardiac causes of dyspnea.[14,17] The American College of Radiology (ACR) states that for dyspnea of suspected cardiac origin, the initial diagnostic imaging should usually be CR followed by transthoracic echo.[2]

CR remains a valuable first line investigation of dyspnea.[14]The ACR states that CR should generally be the first imaging study.[1] It may reveal abnormalities or guide further imaging decisions. Data on the diagnostic utility of chest CT for chronic dyspnea

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

are limited. It is often used following an abnormal CR or if other initial testing is negative. The ACR states that CT may be useful when CR abnormalities require further characterization or clinical findings necessitate additional imaging despite a normal CR.[1] CT without intravenous contrast is usually sufficient unless there is a suspicion for vascular abnormalities. The disadvantage is exposure to ionizing radiation; therefore, CT "requires careful patient selection with consideration given to patient age, risk of diagnostic radiation exposure and estimated diagnostic yield."[17]

Background and Supporting Information

- Dyspnea is the subjective experience of breathing discomfort.

Dyspnea/Shortness of Breath Health Equity Considerations

- Dyspnea disproportionately affects individuals with a low socioeconomic status.

Pre-Operative Assessment (CH-5.2)

CH.SB.0005.2.A

v1.0.2026

- For pre-operative assessment prior to a planned segmental, lobar, or lung removal, as well as for pre-interventional assessment prior to a planned endobronchial valve (e.g., Zephyr valve) placement, the following are medically necessary:
  - "Split Function Studies" (CPT® 78597-Quantitative Differential Pulmonary Perfusion, Including Imaging When Performed or CPT® 78598-Quantitative Differential Pulmonary Perfusion and Ventilation (e.g., Aerosol or Gas), Including Imaging When Performed) or SPECT/CT (CPT® 78830)

    AND/OR
  - CT Chest (CPT® 71250, CPT® 71260 or CPT® 71270) for pre-interventional procedure assessment prior to a planned endobronchial valve (e.g., Zephyr Valve) placement.
  - For robotic assisted lung resection, CT chest (CPT® 71250 OR CPT® 71260) is medically necessary if:
    - Previous diagnostic scan was ≥6 weeks ago
    - CPT® 76497 (Unlisted CT procedure) if a CT Chest has been performed < 6 weeks ago

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Post Endobronchial Valve (EBV) Placement (CH-5.3)

CH.SB.0005.3.A
v1.0.2026

- Suspected Post EBV Complication:
  - Initial evaluation should include a chest x-ray
    - CT Chest without contrast (CPT® 71250) or CT Chest with contrast (CPT® 71260) is medically necessary for:
      - acute loss of benefit, lack of initial benefit, increased dyspnea, sudden chest pain, increased cough, suspected valve malposition/migration, or to evaluate target lobe volume reduction

Evidence Discussion

The most common acute complications following EBV placement are pneumothorax, pneumonia, COPD exacerbation and valve migration.[10] Pneumothorax occurs in 20-30% of individuals, the majority within the first 48 hours after the procedure. Individuals who have an acute increase in dyspnea, cough or chest pain, or an acute perceived loss of benefit, should have a chest X-ray (CR) to rule out pneumothorax. If the CR is non-diagnostic, a CT chest should be done to evaluate the valve position, the target lobe and volume reduction more precisely.[9]

Following EBV placement, it may take several days to one month for significant volume reduction and atelectasis of the target lobe to occur. If no significant lung volume reduction is seen on CR at one month, a CT should be done to evaluate valve position.[10] A CT chest is performed routinely at some centers 6-8 weeks after EBV placement.[9] If there has been no clinical benefit and no lobar atelectasis is evident on CT at 6 weeks, a revision bronchoscopy may be necessary.[11] The two most common causes of lack of benefit are the presence of interlobar collateral ventilation or valve misplacement/migration.

Hemoptysis (CH-6.1)

CH.HS.0006.1.A

v1.0.2026

- Following a chest x-ray performed after hemoptysis started or worsened the following is medically necessary:
  - CT Chest with contrast (CPT® 71260) or CTA Chest (CPT® 71275)
- For recurrent hemoptysis (hemoptysis occurring after medical therapy or embolization), or related to pre-bronchial artery embolization planning, the following is medically necessary:
  - CTA Chest (CPT® 71275) (preferred) or CT chest with contrast (CPT® 71260) if requested

NOTE:

- CT Chest without contrast, (CPT® 71250), is only warranted in individuals with poor renal function or life-threatening contrast allergy.
- There is no data to support the use of CT Chest without and with contrast, (CPT® 71270) in the diagnosis of hemoptysis.

Background and Supporting Information

- The most common causes of hemoptysis are acute respiratory tract infections, respiratory tract neoplasm, bronchiectasis, and tuberculosis. Chest x-ray is the most common initial test because it is easy to obtain, can help lateralize the site of bleeding in 32-80% of cases, and may demonstrate underlying parenchymal abnormalities. If no cause is found on chest x-ray, further evaluation is necessary with CT chest with contrast, CTA chest, and/or bronchoscopy. Angiographic localization of the site of bleeding can be challenging, time-consuming, and requires a significant contrast load; therefore, pre-procedural chest CT and/or bronchoscopy to help localize the bleeding site is valuable. Determination of which arteries to embolize is based on a combination of CT, bronchoscopic localization of bleeding when applicable, and angiographic findings.

Bronchiectasis (CH-7.1)

CH.BR.0007.1.A
v1.0.2026

- High resolution CT Chest (HRCT) without contrast (CPT® 71250) for ANY of the following:
  - To confirm suspected diagnosis of bronchiectasis after an initial x-ray.
  - For known bronchiectasis with worsening symptoms or worsening PFT's.
  - For hemoptysis with known or suspected bronchiectasis.

Evidence Discussion

The British Thoracic Society (BTS) recommends performing a baseline chest x ray (CR) in people with suspected bronchiectasis followed by a thin section (< or equal to 1 mm slice thickness) CT scan to confirm the diagnosis.[7] According to the American College of Radiology (ACR), CR is relatively insensitive but is medically necessary and often performed as initial imaging for evaluation of associated conditions and exclusion of diseases that cause similar symptoms.[9] High resolution CT chest (HRCT) is considered the most accurate imaging modality for the diagnosis of bronchiectasis.[8] The ACR states that CT chest without contrast is medically necessary for suspected bronchiectasis to identify and characterize the severity and distribution of bronchiectasis and to evaluate any associated parenchymal lung diseases.[9] CT chest can help identify an etiology, such as allergic bronchopulmonary aspergillosis, Primary Ciliary Dyskinesia, tracheobronchomegaly, or a foreign body.[7,8]

MRI chest for suspected bronchiectasis is not medically necessary because it is inferior to CT for evaluating lung parenchyma, and its use is mainly limited to research settings.[9]

CR is often the initial chest imaging exam to evaluate acute conditions in people with bronchiectasis, such as pneumonia or hemoptysis. CT chest without contrast is medically necessary for the evaluation of complications and assessing changes in clinical status.[9] CT chest with contrast is medically necessary in the setting of a suspected acute infection and associated complication, such as abscess.[9] The BTS recommends a CT chest for people with a deteriorating clinical status, such as worsening symptoms, increased frequency or severity of acute exacerbations, or decreasing lung function.[7] They recommend a CT chest with contrast if PE is suspected. CTA chest with contrast is medically necessary in the setting of hemoptysis to identify dilated bronchial arteries or systemic collateral vessels and for pre-procedure planning.[8,9]

High quality evidence in favor of repeated imaging is lacking.[8]CR may not show structural changes. Repeat HRCT carries the risk of increased radiation. Individuals with diseases associated with bronchiectasis may be evaluated with CT to help guide

therapy and provide prognostic information.[9]The current indication for repeat HRCT is clinical deterioration.[7])

Bronchiectasis Health Equity Considerations

- Bronchiectasis is more prevalent among females. The most aggressive disease occurs among post-menopausal females.

Adult Cystic Fibrosis (CH-7.2)

CH.BR.0007.2.A
v1.0.2026

- CT Chest without contrast (CPT® 71250) or with contrast (CPT® 71260) is medically necessary for the following (without initial chest x-ray):
  - Suspected or initial diagnosis of Cystic Fibrosis
  - Biennially, (every 2 years), for routine surveillance
  - Persistent respiratory symptoms with reduced lung function despite therapy
  - Exacerbations when chest x-ray is indeterminate
  - Hemoptysis
  - Suspected fungal pneumonia
  - Pre and post-lung transplant evaluation
- See **Bronchiectasis (CH-7.1)**

Evidence Discussion

Imaging is an important method of evaluating the lungs in people with cystic fibrosis (CF). It has a stronger correlation with disease severity than pulmonary function tests and facilitates prompt therapy which may help limit irreversible lung damage.[10] Chest x- ray (CR) is less sensitive than CT chest at detecting early structural changes and disease progression.[4] However, CR is still most commonly used as the first line imaging examination for the assessment of acute complications due to its low cost, availability, low radiation and speed of acquisition.[11] CT is increasingly being used to monitor disease progression and make treatment decisions, but the routine use of CT for short term follow up during pulmonary exacerbations is not recommended due to the risk of a high cumulative radiation dose. Low dose chest CT (LDCT) is useful in individuals with persistent respiratory symptoms and decreased lung function despite appropriate therapy.[4] There is little evidence regarding the optimal timing of CT monitoring. The current best clinical practice in several European CF centers is a CT every two years with a radiation dose as low as reasonably achievable (ALARA). Follow up imaging is determined by individual-dependent clinical factors.[4] The CF Foundation guidelines for adult CF clinical care recommend CR every 2-4 years in those with a stable clinical status and state that imaging should be considered if there are symptoms or signs of an acute pulmonary exacerbation, pneumothorax, lobar atelectasis or hemoptysis.[12,13]

Several emerging techniques offer promising means of pulmonary imaging using less ionizing radiation, including ultra-low dose CT (ULDCT) and MRI.[10,14,18,20] The radiation dose with CR is 0.02mSv, 5.4 mSv for standard dose CT, 1 to 2 mSv for LDCT, and 0.05-0.08mSv for ULDCT. While pulmonary MRI has promise as a means of routinely monitoring CF lung disease, it is currently limited by a lack of availability, high cost, lack

Proprietary Information of UnitedHealthcare.

of validation and standardized protocols, and the need for sedation or anesthesia in some individuals.[4,10]

Adult Cystic Fibrosis Health Equity Considerations

- There are disparities in cystic fibrosis outcomes related to race, ethnicity, socioeconomic status, geographic location, sexuality, and gender identity.
  - People with disadvantaged backgrounds have worse cystic fibrosis health outcomes and tend to die younger than those without.
  - Women tend to have worse cystic fibrosis outcomes than men.

Bronchitis (CH-8.1)

CH.BH.0008.1.A
v1.0.2026

- Chest x-ray is medically necessary as initial imaging if symptoms persist or worsen. Advanced imaging is not medically necessary for bronchitis unless directed by condition specific guideline.
  - See the following guidelines for additional information:
    - For Pneumonia, see: Pneumonia (CH-13.1).
    - For Cough, see: Cough (CH-3.1).
    - For Pleural Effusion, see: Pleural Effusion (CH-18.1).
    - For pulmonary mass, see: Pulmonary Nodule (CH-16.1), Pulmonary Nodule (CH-16.1).

Evidence Discussion

Acute bronchitis is a self-limited respiratory infection characterized by cough due to acute inflammation of the trachea and large airways without evidence of pneumonia.[1, 2.] This syndrome should be distinguished from the common cold, an acute exacerbation of chronic bronchitis and acute asthma.[1]

Cough associated with acute bronchitis typically lasts about two to three weeks. Other diagnoses must be considered when cough persists for more than three weeks.[1] Acute bronchitis is mainly caused by viruses, and antibiotics are not typically indicated in individuals without chronic lung disease[1, 2]. Imaging is primarily used to rule out pneumonia. Evidence-based guidelines from the American College of Chest Physicians state that imaging is not needed in individuals with acute bronchitis symptoms who have normal vital signs and normal lung examination findings.[2]

Asbestos Exposure (CH-9.1)

CH.AE.0009.1.A
v1.0.2026

- Chest x-ray as radiographic screening for asbestos exposure.
  - Stable calcified pleural plaques on chest x-ray do not require advanced imaging of the chest.
- CT Chest is not medically necessary to screen populations at risk for asbestos-related diseases.
- High resolution CT Chest (HRCT) (CPT® 71250) for ANY of the following:
  - Any change seen on chest x-ray
  - Progressive respiratory symptoms that may indicate the development or progression of asbestos related interstitial fibrosis

Evidence Discussion

Several well-conducted epidemiologic studies of occupationally exposed workers, family contacts of workers, and persons living near asbestos mines have demonstrated that exposure to asbestos is associated with an increased incidence of asbestosis, lung cancer, mesothelioma, as well as other neoplasms. Asbestosis is a fibrotic lung disease caused by accumulation of asbestos fibers in the lungs. The diagnosis of asbestosis is most commonly made based on a history of exposure to asbestos, the presence of characteristic radiologic abnormalities, end-inspiratory rales, and other clinical features.[1-3]

A chest x-ray of an individual exposed to asbestos may show pleural plaques, pleural calcifications, pleural fibrosis, or small irregular parenchymal opacities. Lung cancer risk is not elevated among individuals with asbestos-related pleural plaques in the absence of asbestosis.[1-3]

Chest x-ray is currently medically necessary to screen for lung changes resulting from asbestos exposure and is recommended for those who have had relatively heavy exposure to asbestos. However, chest x-rays lack specificity. When a chest x-ray abnormality is indeterminate, High Resolution CT Chest (HRCT) is useful in revealing characteristic parenchymal abnormalities. There is a lack of consensus among experts regarding the value of HRCT for screening of asbestos-related pulmonary disease.[1-3]

Background and Supporting Information

- Asbestosis and asbestos-related diseases include: pleural effusion, pleural plaques, lung cancer, and malignant mesothelioma. The risk of developing mesothelioma increases with increasing intensity and duration of exposure.

COPD (CH-10.1)

CH.PD.0010.1.A
v1.0.2026

- Chest x-ray should be performed initially.
  - CT Chest without contrast (CPT® 71250) or CT Chest with contrast (CPT® 71260) can be performed if:
    - Emphysema is known or suspected and a pre-operative study for Lung Volume Reduction Surgery (LVRS) is being requested. OR
    - For known COPD:
      - individuals with persistent exacerbation OR
      - symptoms out of proportion to disease severity OR
      - FEV1 <45% of predicted
    - PFT's, appropriate laboratory studies, and chest x-ray do not reveal a definitive diagnosis and there is suspicion of an additional diagnosis including, but not limited to:
      - Bronchiectasis
      - Sarcoidosis
      - Emphysema
      - Pneumoconiosis
      - Idiopathic pulmonary fibrosis
      - Langerhans cell histiocytosis
      - Hypersensitivity pneumonitis
      - Bronchiolitis obliterans
      - Lipoid pneumonia
      - Drug toxicity
      - Lymphangitic cancer
      - Alpha-1-Antitrypsin Deficiency
- Lung cancer screening is discussed in the following guideline:
  - See "Screening Indications" in **Lung Cancer Screening (CH-33)**
- Pre-interventional lung procedure assessment prior to a planned endobronchial valve (e.g., Zephyr valve) placement
  - See **Pre-Operative Assessment (CH-5.2)**

Evidence Discussion

Chest x-ray (CR) is usually the appropriate initial imaging study for suspected COPD to exclude alternative diagnoses and evaluate for comorbidities and complications.[1-3] CR, pulmonary function tests (PFT's) and selected blood tests lead to a specific diagnosis

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

in a significant proportion of people with chronic dyspnea.[3] CT has increased sensitivity and specificity for determining the type, severity, and distribution of emphysema and bronchial abnormalities.[1,3] It is an important part of the pre-procedure evaluation process for lung volume reduction surgery, endobronchial valve placement, and lung transplantation.[3] The GOLD 2023 report recommends that CT be considered for individuals with COPD with persistent exacerbations and concern for another diagnosis, such as bronchiectasis or an atypical infection, or symptoms out of proportion to the disease severity suggested by PFT's.[2] Some authors have proposed broadening the definition of COPD to include CT-detected emphysema, air trapping or airway wall thickening, even in the absence of airflow obstruction on spirometry.[5,6]

CT is helpful if a smoking-related interstitial lung disease, such as pulmonary Langerhans cell histiocytosis or Combined Pulmonary Fibrosis and Emphysema, is suspected.[7,8] It is recommended following a diagnosis of alpha-1 antitrypsin deficiency.[9] CT is also used in the evaluation of central airway abnormalities associated with COPD, such as tracheobronchomalacia and excessive dynamic airways collapse.[3] Annual lung cancer screening CT's should be performed in current or former smokers who meet the USPSTF criteria, but screening CT's are not recommended for those with COPD not due to smoking because there is insufficient evidence to establish benefit over harm.[3]

COPD exacerbations are characterized by dyspnea, cough and/or sputum which worsen over a period of less than two weeks.[3] They are mainly caused by respiratory viral infections. CR is often performed to rule out alternative diagnoses, such as pneumonia, pneumothorax or pulmonary edema.

Background and Supporting Information

- COPD includes asthmatic bronchitis, chronic bronchitis, and emphysema. COPD is airflow reduction (FEV1/FVC ratio <0.7 or FEV1 <80% predicted) in the presence of respiratory symptoms, such as dyspnea. Advanced chest imaging is not typically indicated in COPD exacerbation, which is an acute change in baseline dyspnea, cough, and/or sputum beyond normal day-to-day variations.

Interstitial Lung Disease (ILD)/Diffuse Lung Disease (DLD) (CH-11.1)

CH.ID.0011.1.A

v1.0.2026

- EITHER high resolution CT Chest (HRCT) without contrast (CPT® 71250) (the diagnostic modality of choice) OR CT Chest with contrast (CPT® 71260) to evaluate for the following:
  - Interstitial changes or diffuse parenchymal changes identified on other imaging (including chest x-ray) (See **Dyspnea/Shortness of Breath (CH-5.1)**
  - In individuals that have pulmonary symptoms with abnormal pulmonary function studies (PFT's) and a normal chest x-ray and there is high clinical suspicion for ILD or DLD, including but not limited to, the following entities: Hypersensitivity Pneumonitis, Cryptogenic Organizing Pneumonia (COP, formally known as BOOP), and Eosinophilic Pneumonia.
  - Initial imaging to identify ILD/DLD in individuals with a high suspicion for connective tissue disease or diagnosis of connective tissue disease (based upon autoantibody testing, serology, etc.), including, but not limited to:
    - rheumatoid arthritis
    - scleroderma
    - idiopathic inflammatory myopathies (polymyositis, dermatomyositis, inclusion body myositis)
    - systemic lupus erythematosus
    - Sjögren's syndrome
    - mixed connective tissue disease
  - Significant exposure to a substance or medication (linked to ILD/DLD) and concern for:
    - Abstestosis
    - Silicosis
    - Coal miner's lung disease
    - Drug induced pulmonary toxicity
      - Follow-up CT chest (CPT® 71250 or CPT® 71260) for worsening symptoms or PFT's, guide for steroid taper, or baseline prior to re-exposure to offending agent
      - Timing at the discretion of the treating provider
  - At any time for detection of Progressive Pulmonary Fibrosis (PPF), in individuals with ILD of known or unknown etiology, defined by at least one of the following:
    - New or worsening respiratory symptoms

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

        - Worsening PFT's, defined as decline of either:
            - FVC of 5% or greater within the past year
            - DLCO of 10% or greater within the past year
    - Annually in individuals with known pulmonary fibrosis if needed for:
        - serial examination for improvements in diagnostic accuracy, or
        - evaluation of disease reversibility, stability, or progression.
- Concern for interstitial lung disease post-COVID, See **Coronavirus Disease 2019 (COVID-19) (CH-13.2)**
- HRCT can be done even if a regular CT Chest has been done previously. HRCT is done with a thinner-slice protocol that can provide additional details to help determine ILD subtype.
- HRCT can also be done with inspiratory/expiratory and supine/prone views.

Evidence Discussion

ILD is often suspected in those with chronic dyspnea or non-productive cough, especially in the setting of an inhalational exposure or systemic disease known to be associated with lung involvement.[1,7,11] Chest x-ray (CR) and CT chest without contrast are medically necessary for suspected ILD and provide complementary information.[1,7] A normal CR does not rule out ILD, as CR can be normal in up to 10% of individuals with ILD. Its primary function is to evaluate for an alternative diagnosis. CR remains an important imaging modality to screen for occupational lung disease.[1] High resolution CT (HRCT) has higher sensitivity and specificity for ILD. HRCT may help guide a biopsy site or provide a definitive diagnosis, making a biopsy unnecessary.[1,7] CT can provide prognostic information: individuals with honeycombing or a usual interstitial pneumonia (UIP) pattern on CT have increased mortality.[12]

CR and CT chest without contrast are medically necessary for evaluation of an acute exacerbation of ILD.[7] They can help exclude alternative causes for worsening clinical symptoms and confirm abnormalities consistent with progression of ILD. There are no data to support routine surveillance imaging of ILD, but serial CT's can improve diagnostic accuracy and evaluate disease stability, reversibility or progression.[7] The optimal interval for follow up HRCT to determine disease progression in idiopathic pulmonary fibrosis (IPF) is unknown. Raghu et al recommend consideration of an annual HRCT in people with IPF if there is clinical suspicion of worsening fibrosis or to screen for complications such as lung cancer.[7] In people with an ILD other than IPF and radiologic evidence of fibrosis, disease progression on HRCT is one of three criteria used to define progressive pulmonary fibrosis.[7,13]

Interstitial lung abnormalities (ILA) are abnormalities on CT suggestive of ILD in people without a prior clinical diagnosis.[10,14] They are common incidental findings, especially in older people. ILA are a radiologic observation. Differentiation between ILA and clinical or subclinical ILD must be on the basis of a clinical evaluation. When respiratory

Copyright ©2025 United HealthCare Services, Inc.

signs/symptoms or functional impairment is present, ILA likely represent mild ILD. The morphology and distribution of ILA are important: subpleural fibrotic ILA are most likely to progress. There is minimal evidence to support a specific management plan for ILA. Hatabu et al recommend that when ILA are detected, a dedicated HRCT chest can help confirm and characterize the abnormalities, especially if the initial scan was incomplete (i.e., a CT abdomen) or not performed with thin sections.[14] Hunninghake et al recommend that a HRCT should be done in those with ILA.[10] If clinically significant ILD is ruled out, Hatabu et al recommend a repeat CT at 12-24 months for those with subpleural fibrotic ILA or other risk factors for progression to ILD.[14] However, participants in a consensus survey disagreed about repeating a HRCT at the follow up evaluation.[10] People with nonfibrotic nonsubpleural ILA and no symptoms or physiologic impairment do not need reimaging.[14,15]

Background and Supporting Information

- DLD refers to diffuse parenchymal lung diseases or interstitial lung diseases. There are a multitude of pathologies that demonstrate involvement of the alveoli, airways, or both, in addition to the pulmonary interstitium. A single term of ILD would not fully address the entities that are mostly parenchymal in nature, hence the term Diffuse Lung Disease is more technically correct. Both terms are included here for convenience and recognition.
- There is no relevant literature to support the use of CT with IV contrast for initial or follow-up imaging of ILD; however, IV contrast may be of use in evaluation of alternative diagnoses with overlapping clinical features or conditions that also involve the pleura, mediastinum, and pulmonary vessels.
- Progression of fibrosis is typically assessed visually, relying on the percentage of lung volume containing fibrotic features in the upper, mid, and lower lung zones. An increased extent of fibrotic features denotes progression. These may include increased traction bronchiectasis and bronchiolectasis, new ground-glass opacity with traction bronchiectasis, new fine reticulation, increased coarseness of reticular abnormality, new or increased honeycombing, and increased lobar volume loss.

E-cigarette, or Vaping, Product Use–Associated Lung Injury (EVALI) (CH-11.2)

CH.ID.0011.2.A

v1.0.2026

- Chest x-ray is medically necessary as first line imaging for suspected EVALI.
- CT Chest with or without contrast (CPT® 71250 or CPT® 71260) is medically necessary if:
  - Clinical suspicion for EVALI but negative chest x-ray
  - To identify extent of pulmonary involvement identified on chest x-ray
  - Severe (e.g., tachycardia, tachypnea, or hypoxia (O_2 95% or less)) or worsening disease (does not require a repeat chest x-ray)
  - To rule out other diagnoses (infection, pulmonary edema, etc.)
  - Clinical suspicion of pneumothorax or pneumomediastinum (See **Pneumothorax/ Hemothorax (CH-19.1**))

Evidence Discussion

EVALI is a toxic inhalational acute lung injury with imaging and histopathologic patterns of organizing pneumonia and/or diffuse alveolar damage.[16,17] Individuals with EVALI mainly present with respiratory symptoms (e.g., shortness of breath, cough, chest pain), gastrointestinal symptoms (e.g., abdominal pain, diarrhea, nausea, vomiting), and systemic symptoms (e.g., fever, weight loss, fatigue).[22] The diagnostic criteria for EVALI, as defined by the CDC for a "confirmed EVALI" case, is as follows: i) individuals must have vaped within 90 days before the onset of symptoms, ii) bilateral pulmonary opacities on chest imaging, iii) a negative evaluation for infection, iv) no other plausible alternative diagnoses.[22] Chest x-ray (CR) can exclude other diagnoses and is often the first imaging study. CR is not abnormal at initial assessment in all individuals with EVALI. When pulmonary abnormalities are not identified on CR or when further characterization of CR findings are needed to evaluate for another potential cause of symptoms, CT chest can be obtained.[16,17]

Pneumonia (CH-13.1)

CH.PN.0013.1.A
v1.0.2026

- Chest x-ray should be performed initially in all individuals with suspected pneumonia, prior to considering advanced imaging.
  - CT Chest without or with contrast (CPT® 71250 or CPT® 71260) if initial or repeat chest x-ray findings reveal:
    - complication of pneumonia (e.g., abscess, effusion, necrotizing pneumonia, pneumothorax)
    - possible lung mass associated with the infiltrate or persistent radiographic abnormalities on repeat chest x-ray after 6-8 weeks
  - CT Chest without or with contrast (CPT® 71250 or CPT® 71260) for hypoxia and/ or respiratory distress
  - CT Chest without or with contrast (CPT® 71250 or CPT®71260) after initial chest radiograph is negative or equivocal and one of the following:
    - Abnormal vital signs (including hypoxemia, pulse > 100, respiratory rate > 24, fever > 100)
    - Abnormal exam (including respiratory distress, dyspnea and or abnormal lung auscultation)
    - Advanced age (age >75), or other significant comorbidities
- If pulmonary emboli suspected, see **Pulmonary Embolism (CH-25.1).**
- CT Chest without or with contrast (CPT® 71250 or CPT® 71260) for immunocompromised individuals with any of the following:
  - High suspicion for pneumonia despite equivocal or negative chest x-ray
  - Persistent radiographic abnormalities on repeat imaging after 6-12 weeks
  - Multiple or diffuse opacities or nodules

Evidence Discussion

Chest radiography (CR) is the appropriate first imaging modality in the evaluation of suspected pneumonia.[16] The American Thoracic Society (ATS) and the Infectious Diseases Society of America (IDSA) define a clinical diagnosis of pneumonia as symptoms and signs of pneumonia with radiographic confirmation.[1] Chest radiographs should be performed for individuals with symptoms of dyspnea, tachycardia, tachypnea and fever more than 100°F or lung findings suggestive of pneumonia.[28]

CT is more accurate/sensitive than CR and may be medically necessary when there is a high clinical suspicion for pneumonia (typical or atypical) and a delay in diagnosis could be life threatening.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

CT chest without contrast is medically necessary and CT chest with contrast may be medically necessary in immunocompromised people with an acute respiratory illness and a normal/equivocal/nonspecific CR or a CR that demonstrates multiple, diffuse or confluent opacities.[15]

MRI is not medically necessary for the imaging of pneumonia.[2,15] MRI has a potential role for follow up imaging of parenchymal (Chest wall/mediastinal) disease, but CT is more sensitive and is preferred.[15]

Ultrasound chest may be appropriate for the evaluation of parapneumonic effusions. It can also be used to guide pneumonia-related interventions.[2,29-31]

Routine use of follow up chest imaging in adults who are improving and whose symptoms have resolved within 5-7 days is not recommended by the ATS/IDSA.[1] Repeat CR or CT after the completion of therapy is generally reserved for high risk individuals, suspected complications, disease progression or when the clinical course differs from CR interpretation.[16,27] High risk individuals include individuals over the age of 50, smokers, and those with persistent symptoms.[32,33] For immunocompetent individuals with suspected pneumonia, follow-up imaging within 6-12 weeks is medically necessary to confirm resolution. The follow-up imaging modality should be the same modality in which pneumonia was detected.[2]

Pneumonia Health Equity Considerations

Mortality from pneumonia is higher in non-Hispanic Black individuals than non-Hispanic White individuals. These disparities are the greatest in major metropolitan areas.

Click Here to Return to the Main TOC

Coronavirus Disease 2019 (COVID-19) (CH-13.2)

CH.PN.0013.2.A

v1.0.2026

- CT Chest without contrast (CPT®71250), or with contrast (CPT®71260) is medically necessary in the following clinical situations:
  - Imaging for initial diagnosis:
    - Symptomatic COVID-19 positive individuals with underlying comorbidities (including, but not limited to, age > 65 years, chronic lung disease, current or former smoker, chronic kidney disease, chronic liver disease, dementia, diabetes, Down's syndrome, HIV or other primary, secondary or acquired immunodeficiency, mood disorders, BMI ≥30, pregnancy, solid organ or blood stem cell transplant, cerebrovascular disease, substance use disorder, tuberculosis, cardiovascular disease, malignancy, bronchopulmonary dysplasia, chronic infections, or immunocompromised state).
    - Moderate to severe symptomatic individuals with evidence of significant pulmonary dysfunction or damage (e.g., hypoxemia, moderate-to-severe dyspnea), suspected of having COVID-19, regardless of COVID-19 test results or when viral testing is not available, even with a normal chest x-ray (if done).
    - Thromboembolic complications including pulmonary embolism, stroke and mesenteric ischemia are recognized complications of COVID-19. See **Pulmonary Embolism (CH-25.1)**, **Mesenteric Ischemia (AB-6.1)** in the Abdomen Imaging Guidelines, and **Stroke/TIA (HD-21.1)** in the Head Imaging Guidelines for appropriate imaging guidance.
    - Other systemic complications are being recognized as medical knowledge about this condition evolves. Imaging for possible COVID-19 complications should be managed by the appropriate condition based guidelines.
  - Imaging after initial diagnosis:
    - Imaging in the following clinical circumstances:
      - If there is significant worsening of symptoms in a COVID-19 positive individual and imaging will be used to modify individual management.
      - A recovered COVID-19 positive individual with significant residual functional impairment and/or persistence hypoxemia.
        - Symptomatic post-COVID individuals with concern for interstitial lung disease including organizing pneumonia imaging can be considered pre and post treatment.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Evidence Discussion

Chest imaging is not medically necessary as a screening test for COVID-19 in asymptomatic people or in people with suspected COVID-19 and mild clinical features unless they are at risk for disease progression.[7]

The American College of Radiology (ACR) states that CT chest should not be used as a screen or first-line test to diagnose COVID-19.[3] Viral testing is the only specific method of diagnosis and confirmation with a viral test is required even if radiologic findings on chest radiography (CR) or CT are suggestive of COVID-19.

Imaging is medically necessary in people with COVID-19 and a worsening respiratory status or in people who have suspected COVID-19, a high pretest probability of disease, and moderate to severe clinical features.[7] Although less sensitive than CT, chest radiography (CR) is typically the first line imaging modality.[2,7,18]

Johnston et al have proposed a management algorithm for individuals with COVID-19 pneumonia which recommends a clinical assessment with CR and PFT's 3-6 months after discharge.[23] Performance of a high resolution CT chest (HRCT) is based on risk factors (ICU admission, noninvasive or mechanical ventilation; male sex; age > 60) and serial assessment of lung function and symptoms.

There is an increased risk of pulmonary embolus (PE) in people with COVID-19, including both microvascular/ in situ thrombosis and macrothrombotic events.[25] It is currently recommended that the same diagnostic strategy and the same D-dimer threshold be used for people with COVID-19 and suspected PE as in those without COVID-19.[25,26]

Background and Supporting Information

- The role of advanced imaging in the diagnosis and management of COVID-19 is very dynamic in this rapidly evolving condition.
- Comorbidities may include: chronic heart, lung, liver, or renal disease; diabetes mellitus; alcoholism; malignancy; asplenia; organic brain disease (dementia, CVA, delirium).
- Findings on both Chest x-ray and CT Chest are non-specific. Chest x-rays may show patchy opacities with lower lung predominance. CT may show peripheral multifocal ground glass opacities with lower lung predominance. However, a significant portion of cases have opacities without a clear or specific distribution. A reverse halo sign or other findings of organizing pneumonia may be seen later during the course of illness. Atypical findings include isolated lobar or segmental consolidation without ground glass opacities, discrete small centrilobular ("tree-in-bud") nodules, pleural effusion.
  - Pediatric individuals may have less pronounced imaging findings than adults.
- CT Chest abnormalities are common 3 months after discharge in adults who have been hospitalized for COVID-19 and are associated with more severe acute disease.

Click Here to Return to the Main TOC

Fibrosis was seen in a minority of people. Most people re-imaged at one year showed radiologic improvement.

- Major professional society guidelines to date:
  - The American College of Radiology (ACR) recommends that CT Chest should not be used for screening or as a first-line test to diagnose COVID-19.
  - The Centers for Disease Control and Prevention (CDC) recommends viral testing as the only specific method of diagnosis.
  - The CDC has stated that symptoms may appear 2-14 days after exposure to the virus. These symptoms may include:
    - fever or chills
    - cough
    - shortness of breath or difficulty breathing
    - fatigue
    - muscle or body aches
    - headache
    - new loss of taste or smell
    - sore throat
    - congestion or runny nose
    - nausea or vomiting
    - diarrhea
  - The Fleischner Society consensus statement published on April 7, 2020, recommends against the use of imaging in individuals with suspected COVID-19 who are either asymptomatic or have only mild symptoms without evidence of significant pulmonary dysfunction or damage (e.g., absence of hypoxemia, no or mild dyspnea).
  - According to The American Society of Transplantation, screening donors is based on methods below. Screening donors encompasses three different methods.
    - Epidemiologic screening for travel and potential exposures
    - Screening for symptoms suggestive of COVID-19
    - Viral testing (nucleic acid testing of specimens)
    - Screening asymptomatic donors with advanced imaging is not medically necessary.

PPD or TB (Mycobacterium tuberculosis and Nontuberculous Mycobacterial Pulmonary Disease (NTM-PD)) (CH-14.1)

CH.CI.0014.1.A

v1.0.2026

- CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) with ANY of the following:
  - Normal or equivocal chest x-ray with ONE of the following:
    - Positive PPD skin test or other positive tuberculin skin tests OR
    - Positive QuantiFERON-TB Gold OR
    - Suspected active (or reactivated) tuberculosis
  - Suspected NTM-PD (i.e., atypical mycobacterium infection, Mycobacterium avium complex (MAC))
  - If CT Chest is unremarkable, there is insufficient data to support performing subsequent CT Chest unless symptoms develop or chest x-ray shows a new abnormality.
  - Suspected complications or progression of tuberculosis (e.g., pleural tuberculosis, empyema, and mediastinitis)
  - For those with known TB, follow-up CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250) with frequency at the discretion of or in consultation with the pulmonary or infectious disease specialist (not to exceed 3 studies in 3 months).
  - Re-evaluate individuals undergoing active treatment who had abnormalities seen only on CT Chest.

Evidence Discussion

Nontuberculous mycobacterial pulmonary disease (NTM-PD) can be caused by a wide array of pathogens, with the most common including Mycobacterium avium complex (MAC), Mycobacterium kansasii, Mycobacterium xenopi, and Mycobacterium abscessus.

Chest radiography (CR) should be the initial imaging for suspected active M. tuberculosis (MTB) infection based on clinical symptoms and demographics, a newly positive tuberculin skin test (TST), or interferon-gamma release assay (IGRA). CT is medically necessary if CR is equivocal and there is clinical suspicion of active MTB, especially in those with impaired cell-mediated immunity.[11,26] CT may be performed to evaluate suspected complications and monitor response to therapy.[10,12]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

CR is medically necessary to distinguish latent from active MTB in people with evidence of new exposure (a newly positive TST/IGRA or a positive TST/IGRA with unknown prior status) but no clinical symptoms.[1] The yield of CR for active MTB in the absence of clinical symptoms is low. CT is more sensitive than CR for the detection of latent TB.[13,26] CT is recommended when CR is equivocal for active MTB or when a diagnosis of latent MTB may affect future care.[1,14]

When a TST is not available for people who are going to live in a group home, correctional institution or nursing facility, CR is medically necessary as a surrogate screening measure.

Imaging (CR and CT) is an important component in the diagnosis and follow up of nontuberculous mycobacterial pulmonary disease (NTM-PD).[16] The diagnosis and determination of response to therapy are based upon radiologic, clinical, and microbiologic criteria.[17,18] Serial CT imaging is important for monitoring disease progression and response to therapy. Radiologic findings provide prognostic information and may affect treatment recommendations.[18]

Fungal Infections (Suspected or Known) (CH-14.2)

CH.CI.0014.2.A

v1.0.2026

- CT Chest with contrast (CPT® 71260) or High resolution CT Chest (HRCT) without contrast (CPT® 71250):
  - Initial diagnosis of any fungal pneumonia or chest infection
  - Suspected complications or progression of the fungal chest infection (e.g., worsening pneumonitis; pleural effusion, empyema, mediastinitis)
  - Suspected Allergic Bronchopulmonary Aspergillosis (ABPA) in asthmatics with atypical presentation or poor response to conventional therapy
- Follow-up CT Chest with contrast (CPT® 71260) or High Resolution CT Chest (HRCT) without contrast (CPT® 71250) with frequency at the discretion of or in consultation with the pulmonary or infectious disease specialist.
- For suspected fibrosing mediastinitis:
  - CT chest with contrast (CPT® 71260) (preferred imaging) OR
  - MRI Chest without and with contrast (CPT® 71552)
  - CTA chest (CPT® 71275) for:
    - Procedural planning
    - Evaluation of vascular stents

Evidence Discussion

Pulmonary fungal infections can be caused by a wide array of pathogens, including the endemic mycoses (Histoplasma species, Blastomyces species, and Coccidioides species), Cryptococcus species, and Aspergillus species.

CT chest is the imaging method of choice for suspected or known pulmonary fungal infections, especially in immunocompromised hosts.[19,20,30] Imaging findings are not specific but can lead to early detection of infection, help direct further diagnostic procedures and narrow the differential diagnosis.[3,20] CT is also used to monitor response to therapy and identify complications.[19] The diagnosis of certain pulmonary fungal infections and determination of response to treatment require a combination of clinical, microbiologic and radiologic criteria.[21-23] Denning et al recommend follow up imaging 3-6 months after starting anti-fungal therapy for chronic pulmonary aspergillosis, then less frequently, or with any major change of clinical status based on the fact that radiologic change is slow and little change is visible on chest X-ray (CR) or CT in less than 3 months.[23]

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

CT is not medically necessary in the routine evaluation of suspected asthma without a specific indication but may be of value to identify acute complications following a nondiagnostic CR with suspected alternative diagnoses or associated conditions, such as allergic bronchopulmonary aspergillosis.[7,8,28,29] Serological assays can also play a role in the diagnosis of invasive pulmonary aspergillosis, including the galactomannan and beta-d glucan (Fungitell) assays.

Fibrosing mediastinitis (FM) is a rare benign but potentially life threatening process characterized by progressive proliferation of dense infiltrative fibrous tissue in the mediastinum and/or hila. Granulomatous FM is the more common subtype in the US and is typically associated with prior infection with histoplasmosis. Nongranulomatous FM is less common and is usually associated with an autoimmune disorder, drug exposure, or prior radiation. The most common symptoms are cough, dyspnea, hemoptysis, and pleuritic chest pain. Individuals may develop SVC syndrome or post-obstructive pneumonia. Widening of the mediastinum and mediastinal/hilar lymphadenopathy are the most common abnormal findings on chest x-ray. CT chest with contrast is the modality of choice for suspected FM. MRI is equivalent to CT for evaluating extent of disease, but CT is superior for evaluation of airways and calcification. PET CT is nonspecific and not routinely used. Nonsurgical and surgical procedures for individuals with clinical symptoms are related to compression or obstruction of mediastinal structures. CTA chest may be used for procedural planning or to evaluate the patency of vascular stents. There are no consensus guidelines for follow up imaging. No routine imaging is medically necessary for the granulomatous subtype unless there are progressive symptoms or clinical decompensation. Regular surveillance with CT is recommended for the nongranulomatous subtype to rule out malignancy which may not have been sampled in a biopsy.[32]

Suspected Sternal Dehiscence (CH-14.4)

CH.CI.0014.4.A
v1.0.2026

- Sternal wound dehiscence is primarily a clinical determination.
- Chest x-ray is performed prior to advanced imaging to identify abnormalities in the sternal wire integrity and/or a midsternal stripe. Other findings include rotated, shifted, or ruptured wires.
- CT Chest without contrast (CPT® 71250) or CT Chest with contrast (CPT® 71260) for:
  - differentiating sternal wire migration from sternal dehiscence
  - planned debridement and/or repair

See **Infection (MS-9.0)** for concerns for osteomyelitis or soft tissue infection.

Evidence Discussion

Sternal dehiscence is defined as sternal separation with intact sternal wires migrating with a displaced sternal fragment.[24] The diagnosis is often made clinically; however, early signs may be subtle, and it may be clinically occult.. Early detection of sternal dehiscence on chest x-ray (CR) is important.[24] CT may be used in equivocal cases to assess for sternal separation or for preoperative planning.[24,25,31]

CT provides the best evaluation of sternal non-union when suspected based on pain, clicking and clinical evidence of sternal instability for > 3 months in the absence of infection.[24]

Sarcoid (CH-15.1)

CH.SA.0015.1.A
v1.0.2026

- CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250) is medically necessary to:
  - Establish or rule out the diagnosis when suspected
- Subsequent CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250), in known sarcoidosis, for ANY of the following:
  - Development of worsening symptoms
  - New symptoms appear after a period of being asymptomatic
  - Treatment change is being considered
- If CT is equivocal, definitive diagnosis can only be made by biopsy.
- PET/CT should not be used in the standard work-up of all sarcoidosis individuals. There is currently no evidence to support the use of PET/CT for screening.
- PET/CT (CPT® 78815) is medically necessary under the following conditions:
  - Help guide biopsy location if:
    - known lesion on CT Chest is difficult to access, to help identify alternative biopsy location
    - no apparent lung involvement and to identify an extrapulmonary biopsy site
  - Differentiation of reversible granulomatous disease from irreversible pulmonary fibrosis and will affect treatment options
  - Help identify treatment failure where either current treatment will be modified or new treatment will be introduced

Evidence Discussion

Sarcoidosis is a multisystem disease of unknown etiology characterized by the formation of noncaseating granulomas in various organs.[4] The diagnosis is based on three major criteria: a compatible clinical presentation, the finding of nonnecrotizing granulomatous inflammation in a tissue sample, and the exclusion of alternative causes of granulomatous disease.[5] Imaging plays an important role in the diagnosis. Although chest x-ray (CR) is often the first imaging test used, high resolution chest CT (HRCT) is more sensitive than CR for the detection of nodules and subtle fibrosis.[4] Histologic examination of tissue remains the gold standard for reaching a definitive diagnosis.[6] However, in the appropriate clinical context, certain patterns of mediastinal and parenchymal involvement on HRCT are virtually diagnostic of sarcoidosis.[6] The American Thoracic Society (ATS) states that if asymptomatic bilateral hilar lymphadenopathy is found on chest imaging, histologic confirmation is not always required.[5]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

The monitoring of individuals with pulmonary sarcoidosis is not standardized. Changes in imaging along with clinical features have been used to assess changes in disease activity.[7] If spirometry and pulmonary symptoms are worsening, additional chest imaging may be useful to detect progression of pulmonary disease or an alternative diagnosis.[8] HRCT can also provide prognostic information by differentiating reversible from irreversible (i.e., fibrotic) lesions and show complications, such as mycetomas or evidence of pulmonary hypertension.[6]

There is interest in the use of FDG PET CT for the diagnosis and monitoring of sarcoidosis. PET CT may reveal a more easily accessible biopsy site which is not clinically evident.[4,7] It may detect multi-organ and/or extra-thoracic involvement and demonstrate active inflammation not easily recognized by physical exam or other methods.[7,9] Studies have shown that FDG uptake in sarcoidosis represents active granulomatous inflammation.[7] The evaluation of disease activity is valuable when there is doubt regarding the activity of lesions and a change in therapy is being considered.[6] Positive scans should be interpreted with caution, however, because FDG uptake can be present in other inflammatory processes and malignancy. A significant correlation between decreased metabolic activity in the lungs, increased pulmonary function tests and improved symptoms in response to immunosuppressive medication has been demonstrated.[7,9] Most of the data regarding PET CT and sarcoidosis come from retrospective studies. Prospective trials are needed to determine the role of PET CT in monitoring the efficacy of therapy and the importance of abnormal PET CT's in asymptomatic individuals.[9] The threshold SUV that distinguishes active disease from fibrosis has not been determined. Few studies have compared the value of HRCT vs PET CT for diagnosis. Data on appropriate time intervals for follow up assessments and the role of PET-guided therapy are scarce.[9]

Sarcoid Health Equity Considerations

- Sarcoidosis occurs 2.5 times more often in Black individuals and females.
- Individuals who are Black, female, and/or have a low socioeconomic status report lower health-related quality of life, as well as increased rates of symptoms, mortality, and hospitalizations related to sarcoidosis.
- The unequal distribution of care and resources between rural/urban locations and different states may impact the quality of care and health outcomes related to sarcoidosis.

Solitary Pulmonary Nodule – Imaging (CH-16.1)

CH.SN.0016.1.A

v1.0.2026

- For these guidelines, manual nodule measurements should be based on the average of long- and short-axis diameters. The size threshold (<6mm) corresponds to a rounded measurement of 5mm or less in these guidelines. Measurements should be rounded to the nearest millimeter. Prediction models used to estimate malignancy yield better results with the average diameter than with the maximum transverse diameter. The dimension of small pulmonary nodules (<10mm) should be expressed as the average of the maximal long-axis and perpendicular maximal short-axis measurements in the same plane. For larger nodules and for masses larger than 10mm, it is generally appropriate to record both long- and short-axis dimensions, with the long-axis dimension being used to determine the T factor in lung cancer staging and being a criterion for tumor response to treatment.
- A pulmonary nodule can be determined to have changed in size when its average diameter has increased or decreased by at least 2mm (rounded to the nearest millimeter). Smaller changes do not reliably indicate change.
- Maximum intensity projection (MIP), and Minimum intensity projection (MinIP) are 2D projections of the volumetric (3D) acquisition data. These projections may be of use in evaluation of pulmonary nodules, but these projections are included in the cross sectional imaging base codes, and is not separately reimbursable.
- EITHER CT Chest with contrast (CPT® 71260) OR CT Chest without contrast (CPT® 71250) is medically necessary initially for discrete nodule(s) in the following scenarios:[1,2,3]
  - Lung nodule(s) seen on an imaging study other than a “dedicated” CT or MRI Chest. Examples of other studies:
    - Chest x-ray
    - CT abdomen
    - MRI spine
    - Coronary CTA (unless full lung field are noted to be included)
  - But NOT in the following which are considered initial dedicated advanced chest imaging:
    - CT Chest without and with contrast (CPT® 71270)
    - CTA Chest (CPT® 71275)
    - MRI Chest without contrast (CPT® 71550)
    - MRI Chest without and with contrast (CPT® 71552)
    - MRA Chest without and with contrast (CPT® 71555)

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Comparisons should include the earliest available study and the more recent previous CT Chest scans to determine if nodule was present and stable.
  - Similar-sized pleural nodule(s) is treated as a pulmonary nodule(s)
- The size of the lung or pleural nodule(s) is crucial information for decisions making regarding follow-up. The largest of multiple lung and/or pleural nodules will guide the surveillance interval. (See **Incidental Pulmonary Nodules Detected on CT Images (CH-16.2)**, and **Pleural-Based Nodules and Other Abnormalities (CH-17.1)**
- A lung nodule is defined as an approximately rounded opacity (more or less well-defined) measuring up to 3cm in diameter.
- Rounded lesions measuring more than 3cm in diameter are termed lung masses and should be considered indicative of lung cancer until histologically proven otherwise. Approach to lung masses differ from that of nodules and these guidelines are specifically for those abnormalities, occurring within the chest, that meet the definition of a pulmonary nodule(s).

Evidence Discussion

A pulmonary nodule is defined as a well or poorly defined rounded opacity < 3cm in diameter. Focal pulmonary lesions > 3cm are considered masses. Nodule measurement is currently determined by standard linear measurement with electronic calipers. Measurements and averages should be expressed to the nearest whole millimeter. The dimension of small pulmonary nodules (<10mm) should be expressed as the average of the maximal long-axis and perpendicular maximal short-axis measurements in the same plane. For larger nodules and masses, both long- and short-axis dimensions should be recorded.[10] Semi-automated nodule volumetry has superior sensitivity for detecting growth and is recommended as the preferred method by the British Thoracic Society (BTS), but it requires dedicated software and is currently not widely used in clinical practice.[10,12] Nodule growth is defined as an increase of > 1.5mm (> 2 mm^3) by the Lung-RADS criteria, greater than or equal to 2mm change in average diameter by the Fleischner criteria or an increase of at least 25% in volume by the BTS.[1,12,14] A number of studies have established the advantage of post-processing 3D CT techniques, such as maximum intensity projection (MIP), minimum intensity projection (MinIP) and volume rendering (VR) in the detection and assessment of pulmonary nodules.[9,12,15]

If an indeterminate nodule is seen on a CR or CT, prior studies should be reviewed to determine possible growth or stability, including comparison with the earliest available study and more recent ones.[1-3] If stability of a nodule seen on CR cannot be determined, CT chest is appropriate.[2,3] CT is the modality of choice to evaluate pulmonary nodules.[3] Intravenous contrast is not required to identify or characterize nodules.[18] The size of the nodule is crucial for determining the appropriate timing of follow up surveillance imaging.[1]

Click Here to Return to the Main TOC

For nodules which are detected incidentally on incomplete thoracic CT scans (e.g., cardiac, neck, spine or abdominal CT), the Fleischner society recommends no follow up for most nodules < 6mm based on the estimated low risk of malignancy. The ACR states that an optional follow up CT may be done at 12 months for nodules < 6mm with a suspicious morphology and/or upper lobe location.[3] For nodules 6-8mm, Fleischner and ACR guidelines recommend a CT chest after the appropriate interval (3-12 months, depending on clinical risk). For a nodule > 8mm or a very suspicious nodule, an immediate CT chest is recommended.[1,3]

Background and Supporting Information

Abnormality examples include: mass, opacity, lesion, density, nodule, and calcification.

Incidental Pulmonary Nodules Detected on CT Images (CH-16.2)

CH.SN.0016.2.A
v1.0.2026

Solid Pulmonary Nodules

- These time intervals refer to the time from initial detection of the nodule(s).

Incidentally Detected Solid Pulmonary Nodules Follow-up Recommendations				
Nodule Type	**<6mm (<100 mm ^{3})**	**6–8mm**	**>8mm**	**Comments**
Single Nodule	Follow-up (optional) CT at 12 months. No routine follow-up if stable at 12 months	CT at 6–12 months, then CT at 18–24 months if stable *For an 8mm solid nodule PET request, see CH-16.4	CT at 3 months, then CT at 6-12 and then at 18-24 months if stable. Consider PET/CT* or biopsy	Certain individuals at high-risk with suspicious nodule morphology, upper lobe location, or both may warrant 12-month follow-up
Multiple Nodules	Follow-up (optional) CT at 12 months. *No routine follow-up if stable at 12 months	CT at 3–6 months, then at 18–24 months if stable	CT at 3–6 months, then at 18–24 months if stable. Consider PET/CT* or biopsy	Use most suspicious nodule as a guide to management. Follow-up intervals may vary according to size and risk.

- *PET/CT consider for ≥8mm solid lung nodule or solid component of a sub-solid nodule, not for groundglass opacity.
- Follow-up indications after PET/CT:

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- If a PET/CT was found to be negative, follow-up with CT at 3 months, 9 months, and 21–24 months, if stable.
- If a PET/CT was found to be positive, a biopsy was negative, non-diagnostic, or biopsy not performed, follow-up with CT at 3 months, 9-12 months, and 24 months, if stable.

- These criteria are not intended for use in the following groups:
  - Individuals aged 35 years or younger
    - Considered to have an overall low risk for pulmonary malignancy
    - In this age group, nodules are most likely to be infectious rather than cancer
    - Management of incidentally-found pulmonary nodules in this group should be individualized
  - Known primary cancer with risks for metastases
  - Immunocompromised individuals at risk for infection

Sub-Solid Pulmonary Nodules

- These time intervals refer to the time from initial detection of the nodule(s).

Incidentally Detected Sub-Solid Pulmonary Nodules Follow-up Recommendations			
Nodule Type	**<6mm (<100mm ^{3})**	**≥6mm (≥100mm^3)**	**Comments**
Single Ground glass opacity (GGO)	Consider follow-up at 2 and 4 years. If solid component(s) or growth develops, consider resection.	CT at 6–12 months to confirm persistence, then follow-up with CT every 2 years until 5 years	In certain suspicious nodules, <6mm, consider follow-up at 2 and 4 years. If solid component(s) or growth develops, consider resection.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Incidentally Detected Sub-Solid Pulmonary Nodules Follow-up Recommendations			
Single Sub-solid	Consider follow-up at 2 and 4 years. If growth develops, consider resection.	CT at 3–6 months to confirm persistence. If unchanged and solid component remains <6mm, then annual CT should be performed for 5 years. If the solid component has suspicious morphology (i.e., lobulated margins or cystic components), is >8mm or is growing: Consider PET/CT* or biopsy	In practice, part-solid nodules cannot be defined as such until ≥6mm. Persistent part-solid nodules with solid components ≥6mm should be considered highly suspicious.
Multiple Sub-Solid	CT at 3–6 months. If stable, consider CT at 2 and 4 years.	CT at 3–6 months. Subsequent management based on the most suspicious nodule(s).	Multiple <6mm pure ground-glass nodules are usually benign.

• *PET/CT consider for ≥8mm solid lung nodule or solid component of a sub-solid nodule, not for groundglass opacity.

- Follow-up indications after PET/CT:
  - If a PET/CT was found to be negative, follow-up with CT at 3 months, 9 months, and 21–24 months, if stable.
  - If a PET/CT was found to be positive, a biopsy was negative, non-diagnostic, or biopsy not performed, follow-up with CT at 3 months, 9-12 months, and 24 months, if stable.
- These criteria are not intended for use in the following groups:
  - Individuals aged 35 years or younger
    - Considered to have an overall low risk for pulmonary malignancy
    - In this age group, nodules are most likely to be infectious rather than cancer
    - Management of incidentally-found pulmonary nodules in this group should be individualized
  - Known primary cancer with risks for metastases

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

  - Immunocompromised individuals at risk for infection
- Sub-solid nodules may either be a part-solid nodule, comprising of both solid and ground glass components or a pure ground glass nodule, the latter may also be referred to as "non-solid".
  - Follow-up after year 5 is medically necessary every 2-4 years for at least 10 years if requested.
- For pulmonary nodule follow-up studies a CT Chest without IV contrast (CPT® 71250) is medically necessary. IV contrast is medically necessary as requested.

Pulmonary Cyst(s)

- May represent a rare form of adenocarcinoma, squamous cell carcinoma, or small cell carcinoma.
- Short-term initial imaging to exclude rapid growth is medically necessary at 3-6 months.
- Further imaging can be managed according to the sub-solid pathway above.

Endobronchial Lesion

- CT chest without contrast (CPT® 71250) at 3 months to confirm resolution or persistence
- If persistent, direct visualization with bronchoscopy is medically necessary

Evidence Discussion

A pulmonary nodule is defined as a well or poorly defined rounded opacity < 3cm in diameter. The Fleischner Society guidelines for the management of incidental pulmonary nodules detected on CT were last updated in 2017.[1] The purpose of the guidelines is to minimize both the number of unnecessary follow up exams and the chance of a malignancy advancing in stage during CT follow up prior to diagnosis. Surveillance is most appropriate if there is a very low probability of cancer or a high risk of complications from surgery or biopsy.[2] It is important to establish the clinical probability of malignancy before ordering imaging.[1,2,12] The Fleischner guidelines are not intended to apply to people younger than 35, people with known primary cancers at risk of metastases or to immunocompromised people at risk of infection. They do not apply to individuals with unexplained fever or respiratory symptoms.[3] For individuals younger than 35, lung cancer is rare. Management should be on a case by case basis, and the use of serial CT's should be minimized.[1]

Solid nodules < 6mm do not require follow up in individuals at low risk of lung cancer or in all individuals at high risk. Nodules which have a suspicious morphology or an upper lobe location may be followed up with a CT in 12 months. Solid nodules 6-8mm may be followed with a CT at 6-12 months in low risk individuals with a further follow up at 18-24 months in high risk individuals. Two follow up CT's should be sufficient to rule out growth in most individuals.

Proprietary Information of UnitedHealthcare.

For solid nodules >8 mm, the options are CT surveillance, an FDG PET/CT, tissue sampling or a combination of these. Surveillance CT scans for solid nodules >8 mm may be done at 3 months, 6-12 months and 18-24 months.[1] The American College of Chest Physicians (ACCP) guidelines recommend a PET/CT or nonsurgical biopsy for solid nodules of at least 8mm when the pretest probability of malignancy is low to moderate.[2] The pretest probability affects the interpretation of PET/ CT results: high risk individuals are at risk of false negative results and low risk individuals are at risk of false positive results.[12] If there is a high pretest probability of cancer, a negative PET/ CT does not reliably rule out cancer and either continued surveillance for at least 2 years or tissue sampling is advised.[2,13] The ACCP states that the optimal interval for surveillance CT's for solid nodules >8mm is not determined, but standard practice is 3-6 months, 9-12 months and 18-24 months. They suggest surveillance with CT if the clinical probability of cancer is very low, the clinical probability of malignancy is low and a PET CT is negative, a PET CT is negative and a needle biopsy is non-diagnostic, or an informed individual prefers a non-aggressive approach. If a solid nodule shows clear growth on serial CT's, a non-surgical biopsy or surgical resection is recommended unless there are specific contraindications.[2] A surgical diagnosis is recommended if there is a high clinical probability of lung cancer, the nodule is intensely hypermetabolic on PET/CT, a non-surgical biopsy is suspicious for cancer or an individual prefers a definitive diagnosis.[2]

Multiple solid nodules <6mm are usually benign, representing granulomas or intrapulmonary lymph nodes. A 12 month follow up CT may be considered in high risk individuals. If there is clinical evidence of infection or the individual is immunocompromised, infection should be considered. A short term follow CT may be appropriate. Multiple solid nodules with at least one nodule greater than or equal to 6 mm can be followed with CT's at 3-6 months and 18-24 months. Management should be based on the largest/most suspicious nodule. Most metastases will grow over 3 months. The risk of cancer increases as the number of nodules increases from 1 to 4 but decreases if the number is greater than 4.

Subsolid nodules (SSN) include pure ground glass nodules (GGN) and part-solid nodules (PSN). SSN are more likely to be malignant than solid nodules but have a better prognosis than lung cancers which present as solid nodules.[12] Many have slow growth rates and may remain stable for years. Pure GGN < 6mm do not require routine follow up. However, this should not preclude the option of follow up CT's at 2 and 4 years in high risk individuals. GGN greater than or equal to 6mm can be followed at 6-12 months and then every two years until 5 years. The Fleischner Society states that these guidelines are not intended to preclude either shorter or longer term follow up in individuals when deemed clinically appropriate. A previous study found growth in 7% of part-solid nodules that had previously been stable for 3 years, and another study found growth >2mm in 13% of nodules after 5 years of stability.[21] The ACCP states there is controversy regarding how long to follow part solid or ground glass nodules and

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

that follow up over several years may be appropriate. In appropriate individuals, follow-up after 5 years, every 2-4 years, can be considered for at least 10 years, taking into account comorbidities, life expectancy, and individual preferences.[21]

Solitary PSN < 6mm do not require routine follow up. A follow up CT may be done at 2 and 4 years. For PSN greater than or equal to 6mm with a solid component < 6mm, a follow up CT may be done at 3-6 months and then annually for a minimum of 5 years. The 5 year period is somewhat arbitrary but considered reasonable if the nodule is unequivocally stable during that time period. If the solid component is at least 6mm, follow up at 3-6 months should be done. A persistent PSN with a solid component of at least 6mm or a growing solid component is highly suspicious. If the nodule has suspicious morphology, if the solid component is growing or > 8mm, PET/CT or biopsy should be considered.[1,12] Multiple PSN < 6mm are often infectious. A repeat CT can be done at 3-6 months, then at 2 and 4 years. If at least one of the nodules is greater than or equal to 6mm, a repeat CT can be done at 3-6 months, and management should be based on the most suspicious nodule.

The volume of lung nodules is significantly larger in CT chest with contrast compared to CT chest without contrast. Whichever CT protocol is used initially should also be used in all follow-up scans to avoid the risk of missing any relevant nodule growth.[24,25]

Pulmonary cystic lesions may represent a cyst-related primary lung malignancy. There are no uniform surveillance criteria for these lesions, but some authors recommend a CT at 3-6 months to exclude rapid growth and then follow up CT's according to the SSN nodule guidelines.[8]

NCCN guidelines for the management of incidental pulmonary nodules are consistent with the Fleischner guidelines.[6,7] For pulmonary nodules detected on lung cancer screening CT's, adherence to the American College of Radiology (ACR) Lung-RADS guidelines is recommended.[1,3,6,7,14] The British Thoracic Society and ACCP guidelines do not distinguish the management of screening-detected nodules from nodules detected incidentally.[2,12]

Interval Imaging Outcomes (CH-16.3)

CH.SN.0016.3.A
v1.0.2026

- Further advanced imaging is not medically necessary if a nodule has been:
  - Stable for 2 years
    - Nodules(s) stable on chest x-ray
    - Nodule(s) ≥6mm stable on CT Chest
  - Stable for 1 year
    - Nodule(s) <6mm
  - At any time, if:
    - classically benign characteristics by chest x-ray or previous CT (e.g., benign calcification pattern typical for a granuloma or hamartoma)
    - decreasing in size, (≥ 6mm at start, should be followed for a 2 year period as outlined in CH-16.2) disappearing nodule(s)
- For clinically significant lung nodule(s) (lung nodules not meeting the above criteria) which increase in size or number, serial CT screening or surveillance are not medically necessary.
  - In individuals who do not meet PET criteria (per CH-16.4) or in individuals in which biopsy is not being considered, serial CT may be performed per CH-16.2.

Evidence Discussion

If a chest x-ray (CR) or chest CT has demonstrated that a pulmonary nodule has benign characteristics, further imaging is not medically necessary. Benign characteristics include intranodular fat or a diffuse, central, laminated or popcorn pattern of calcification.[2]

If an indeterminate nodule is seen on a CR or CT, prior studies should be reviewed to determine possible growth or stability, including comparison with the earliest available study and more recent ones.[1-3] If stability of a nodule seen on CR cannot be determined, CT chest is appropriate.[2,3] If a solid nodule has been stable for at least 2 years, no additional evaluation is necessary.[2] Two years of radiographic stability is considered strong presumptive evidence of a benign nodule. For solid nodules seen on CT, further follow up is not needed if nodules < 6mm have been stable for one year or if nodules greater than or equal to 6mm have been stable for two years.[1] Malignant nodules show a wide range of growth rates with some demonstrating regression at times. Solid nodules greater than or equal to 6mm that decrease in size but do not completely resolve should be followed to resolution or lack of growth over 2 years.[2,12] For situations where PET, CT, and/or biopsy are not reasonable choices, ongoing

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

surveillance would be medically necessary. Clinically significant nodules that are not amendable to PET and/or biopsy may undergo serial CT exams per CH-16.2.

There is controversy regarding how long to follow part solid or ground glass nodules. Follow up over several years may be appropriate.[2] The Fleischner guidelines state that subsolid nodules <6mm may be followed for up to 4 years but that the guidelines are not intended to preclude either shorter or longer term follow up in individuals when deemed clinically appropriate.[1] Subsolid nodules greater than or equal to 6mm may be followed for 5 years. The 5 year period is "somewhat arbitrary but considered reasonable if the nodule is unequivocally stable during that time period."[1]

PET/CT should be considered for solid nodules greater than or equal to 8mm.[1,2] If a solid nodule shows clear growth on serial CT's, a non-surgical biopsy or surgical resection is recommended unless there are specific contraindications.[2] Non-solid nodules which grow or develop solid components are often malignant and further evaluation and/or resection should be considered.[2,14]

If a CT demonstrates multiple solid nodules <6mm and there is clinical evidence of infection or the individual is immunocompromised, infection should be considered and a short term follow up CT may be appropriate.[1] Certain findings on a lung cancer screening CT which suggest an infectious or inflammatory process (e.g., >6 new nodules or solid nodules which are greater than or equal to 8mm appearing in a short interval) are reported as Lung-RADS 0 and may be followed up with a LDCT in 1-3 months.[14] Some findings indicative of an infectious/inflammatory process may not warrant short-term follow-up (e.g., tree-in-bud nodules or new <3 cm ground glass nodules).

Background and Supporting Information:

- Approximately 20% of observed cancers have decreased in size at least at some point during their observation period. Therefore, a decreasing size of a nodule cannot be a reliable indicator of being benign.
- For nodules that increase in number, this is not meant for known stable or benign nodules to be counted.
  - Example, known 4mm nodule stable for 3 years, now presents with a new solid 8mm pulmonary nodule, follow-up will be driven by new nodule size and type.
  - Example #2, known granuloma 5mm from prior CT Chest one year ago and now CT Chest reveals a new 6 mm sub-solid nodule, follow-up would be driven by the new nodule size and type.

PET (CH-16.4)

CH.SN.0016.4.A

v1.0.2026

- PET/CT (CPT® 78815) for a solid lung nodule ≥8mm on dedicated advanced chest imaging, as described in **Solitary Pulmonary Nodule – Imaging (CH-16.1).** See **Non-Small Cell Lung Cancer – Suspected/Diagnosis (ONC-8.2)** in the Oncology Imaging Guidelines for lung mass ≥3.1cm.
  - If there is a history of malignancy, refer to the appropriate Oncology restaging/ recurrence guideline for indications for PET imaging.
  - Pleural nodule, See **Pleural-Based Nodules and Other Abnormalities (CH-17.1)**
  - Serial PET studies are not medically necessary
  - Not medically necessary for infiltrate, ground glass opacity, or hilar enlargement
  - Mediastinal lymphadenopathy - See **Mediastinal Lymphadenopathy (CH-2.3)** or Sarcoid concerns – See **Sarcoid (CH-15.1)**
- If a CT finding led to ordering a PET scan, and if that CT was >3 months ago, a repeat CT (CPT® 71250) or (CPT® 72160) is medically necessary prior to considering a PET scan.
  - A change in the status of the original finding may find that a PET scan is no longer medically necessary.

Evidence Discussion

PET/CT may be performed for evaluation of a solid lung nodule greater than or equal to 8mm on chest CT.[1,2,6,7] PET/CT has good sensitivity and moderate specificity for detecting malignancy in individuals with a high risk of cancer and a nodule greater than or equal to 10mm.[12] Consensus opinion is that that nodules <8 to 10mm are not reliably characterized by PET/CT.[2,12] The false negative rate of PET/CT is higher for nodules <8mm and for malignancies with low metabolic activity, such as adenocarcinoma in situ or well differentiated carcinoid tumor. PET/CT has a lower sensitivity and higher false negative rate for ground glass or part solid nodules.[2,12] Infections and inflammatory disorders may cause false positive results.

Repeating a PET/CT is discouraged. If there is a high pretest probability of cancer, a negative PET/CT does not reliably rule out cancer and either continued surveillance for at least 2 years or tissue sampling is advised.[2,13] If a solid nodule shows clear growth on serial CT's, a non-surgical biopsy or surgical resection is recommended unless there are specific contraindications.[2] A surgical diagnosis is recommended if the nodule is hypermetabolic on PET/CT.[2]

PET/CT may be indicated for the pre-treatment staging of individuals with confirmed or strongly suspected lung cancer, as detailed in the oncology guidelines.[2,6,7]

Background and Supporting Information

- A **nodule** is any pulmonary or pleural lesion that is a discrete, spherical opacity 2-30mm in diameter surrounded by normal lung tissue. A larger nodule is called a mass. Entities that are not nodules, and are considered benign, include non-spherical linear, sheet-like, two-dimensional or scarring opacities.
- **Malignant** nodule features can include spiculation, abnormal calcification, size greater than 7-10mm, interval growth, history of a cancer that tends to metastasize to the lung or mediastinum, and/or smoking history.
  - A nodule that grows at a rate consistent with cancer (doubling time 100 to 400 days) may be sampled for biopsy or resected.
  - Less than 1% of <6mm lung nodules are malignant.
  - Three percent of all 8mm lung nodules are malignant.
  - Only one follow-up at 6-12 months is sufficient for 6-8mm nodules and not all require traditional 2 year follow-up.
  - The larger the solid component of a subsolid nodule, the greater the risk of invasiveness and metastases.
  - Increased risk of primary cancer as the total nodule count increased from 1 to 4 but decreased risk in individuals with 5 or more nodules, most of which likely resulted from prior granulomatous infection.
  - A nodule that does not grow in 6 months has a risk of malignancy at <10%.
- **Benign** features in solid nodules can include benign calcification (80% granuloma, 10% hamartoma), multiple areas of calcification, small size, multiple nodules, negative PET, and stability of size over 2 years.
- **Ground glass** or subsolid opacities, which can harbor indolent adenocarcinoma with average doubling times of 3–5 years.
- **Repeat PET** is discouraged. If the original PET is positive, biopsy may be performed. If the original PET is negative but subsequent CT Chest shows an increase in nodule size, biopsy may be performed.
- **Positive PET** is defined as a standardized uptake value (SUV) in the lung nodule greater than the baseline mediastinal blood pool. A positive PET can occur with infection or inflammation, including absence of lung cancer with localized infection, presence of lung cancer with associated (post-obstructive) infection and/or related inflammation.
- **False negative PET** can be seen in individuals with adenocarcinoma in situ (formally known as bronchoalveolar carcinoma), carcinoid tumors, a small size nodule, non-solid or ground glass opacity. High pre-test likelihood of malignancy with negative findings on PET only reduces the likelihood of malignancy to 14%; while in an individual with a low pre-test likelihood (20%) of malignancy, a negative PET reduces the likelihood of malignancy to 1%.

Pleural-Based Nodules and Other Abnormalities (CH-17.1)

CH.PB.0017.1.A

v1.0.2026

- CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) (with contrast is preferred for initial evaluation) is medically necessary for pleural nodule(s).
  - Pleural nodule(s) seen on an imaging study other than a "dedicated" CT or MRI Chest.
  - Pleural nodule(s) identified incidentally on any of the following dedicated chest studies can replace CT Chest as the initial dedicated study.
    - CT Chest without and with contrast (CPT® 71270).
    - CTA Chest (CPT® 71275).
    - MRI Chest without contrast (CPT® 71550).
    - MRI Chest without and with contrast (CPT® 71552).
    - MRA Chest without and with contrast (CPT® 71555).
  - After preliminary comparison with any available previous chest films to determine presence and stability
  - Using largest measurement of multiple nodule(s). (See **Solitary Pulmonary Nodule – Imaging (CH-16.1)**)
  - Following the Fleischner Society Guidelines for high-risk. (See **Incidental Pulmonary Nodules Detected on CT Images (CH-16.2)**)
- PET/CT (CPT® 78815) is medically necessary if dedicated CT or MRI Chest identifies a pleural nodule/mass or defined area of pleural thickening that is ≥8 mm when there is a likelihood of malignancy including current or previous malignancy, pleural effusion, bone erosion, chest pain.
- For diagnosis or suspicion of pulmonary sequestration:
  - CT chest with contrast (CPT® 71260) OR CTA Chest (CPT® 71275)
  - 3D reconstruction as requested (CPT® 76377) or (CPT® 76376)

Evidence Discussion

- CT Chest is medically necessary for the evaluation of pleural nodules.[1-3] CT scan is widely available and allows for easy access to isotropic 3-D reformatting.[3] A study looking at the utility of CT in investigation for malignancy showed a sensitivity of 68%, a specificity of 78%, a positive predictive value of 80% and a negative predictive value of 65% when CT findings were reported as malignant.[3] CT also carries the risk of exposure to iodinated contrast and ionizing radiation.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- Follow up for previously detected pleural nodules follows guidelines addressed elsewhere in these guidelines (See **Solitary Pulmonary Nodule – Imaging (CH-16.1)** and **Incidental Pulmonary Nodules Detected on CT Images (CH-16.2)**.[1]
  - Of note, a study looking at over 8,700 LDCT chest scans identified 943 noncalcified nodules attached to the costal pleura, of these 897 were < 10mm in size. There were 603 that were either lentiform, oval, semicircular or triangular in shape and had smooth margins. All of these nodules, that met these qualifications of shape, size and smooth margins, were benign. Follow-up with annual screening, rather than more immediate work-up, was recommended.[2]
- PET/CT may be considered when the identified pleural nodule/mass or thickening is ≥ 8mm and there is a likelihood of malignancy.[1] PET/CT may be useful in differentiating between benign and malignant disease; however, studies have shown a broad range of sensitivities (88-100%) and specifies (35-100%).[3] PET/CT may be complicated by false positives such as infections and prior pleurodesis with talc, or false negatives such as low grade/low metabolic activity epithelioid mesothelioma.[3]

Background and Supporting Information

- Pleural nodule/mass or thickening without suggestion of malignancy would undergo surveillance or biopsy.
- A study looking at over 8,700 LDCT chest scans identified 943 noncalcified nodules attached to the costal pleura, of these 897 were <10mm in size. There were 603 that were either lentiform, oval, semicircular or triangular in shape and had smooth margins. All of these nodules, that met these qualifications of shape, size and smooth margins, were benign. Follow-up with annual screening, rather than more immediate work-up, was recommended.

Pleural Effusion (CH-18.1)

CH.EF.0018.1.A
v1.0.2026

- CT Chest with contrast (CPT® 71260) is medically necessary after:
- Chest x-ray, (upright posterior/anterior/lateral best), (lateral decubitus films can improve sensitivity); **and**

  one of the following:

  - Thoracentesis, (if possible) to determine if fluid is exudative or transudative and remove as much as possible (this fluid can obscure the underlying lung parenchyma and possibly a mass)
  - Concern for loculated effusion, empyema, paramediastinal location, subpleural lung abscess or cavitation
  - Check position of chest tube(s) or drainage catheters
  - Surgical planning
- Chest ultrasound (CPT® 76604) can be used as an alternative or adjunct to chest x-ray to evaluate for the presence of fluid within the pleural spaces and guide thoracentesis.

Evidence Discussion

The most common initial diagnostic test suggesting a pleural effusion is often chest radiography (CR). CR remains the most accessible form of chest imaging and will often be the initial study for suspected pleural disease.[1,2] Lateral decubitus CR has higher sensitivity and specificity for pleural effusion than other positions.[3] However, complicated effusions are often loculated and may not layer dependently. Lower lobe consolidation may mask the presence of an effusion. The American Association for Thoracic Surgery (AATS) states that CR, although useful as a first step, should be combined with additional imaging if pleural space infection is suspected.[2,9] The American College of Radiology (ACR) states that consensus recommendations endorse CR as the initial imaging modality for suspected parapneumonic or malignant effusion, but there are limited empiric data to support this.

Ultrasound (US) is at least as effective as lateral decubitus views for the detection of pleural fluid and provides a better estimation of fluid volume.[1-3] When standard CR cannot rule out a pleural effusion, US has largely replaced decubitus views due to its speed, portability and greater sensitivity. Identification of a pleural effusion for possible US-guided thoracentesis is the primary reason for chest US. The AATS guidelines state that CR and US are class 1 recommendations (should be done) for suspected pleural space infection.[2] US is more sensitive than CR for detecting pleural effusion.[6,10]

Proprietary Information of UnitedHealthcare.

Although diagnostic imaging plays an important role in the evaluation of pleural effusions, thoracentesis with pleural fluid analysis remains the necessary first invasive step. Pleural fluid analysis is considered mandatory unless the clinical presentation suggests a high pretest probability of a transudative effusion.[1] Initial evaluation should include an ultrasound (US)-guided thoracentesis to categorize the effusion as a transudate or exudate and obtain specimens for microbiology and cytology.[4,5] If a parapneumonic effusion is suspected, diagnostic aspiration must be performed to identify individuals with a complicated effusion that requires drainage.[2,4]

CT is not used routinely as the initial imaging study for pleural effusion unless there is suspicion for loculated fluid in an interlobar fissure or paramediastinal location, or CR demonstrates parenchymal lesions suggestive of cancer, septic emboli or cavitation. CT can better distinguish between a loculated empyema and subpleural lung abscess. CT with IV contrast optimizes imaging of the pleura. CT chest with contrast is a class 2a recommendation (reasonable) for suspected pleural space infection in the AATS guidelines.[2] If the etiology of an exudative effusion cannot be identified, or if it is not safe to perform a thoracentesis, a CT chest with contrast is medically necessary.[4,5] The American College of Radiology (ACR) states that CR or CT chest with IV contrast is medically necessary as initial imaging for people with recent pneumonia and suspected parapneumonic effusion or for people with dyspnea, cough or chest pain with a suspected malignant pleural effusion. Thoracentesis and chest CT cannot rule out malignancy or tuberculosis. Pleural biopsy is indicated for a recurrent undiagnosed exudative effusion.[1,4,5] When a diagnosis cannot be made, monitoring with interval CT scans for up to 2 years is medically necessary.[5] CT is used in the diagnosis and management of late-stage empyema and malignant pleural effusion and can be used to check the position of drains and plan for surgical intervention.[1] CT scans have high specificity but low sensitivity in distinguishing benign from malignant pleural effusion.[6]

Background and Supporting Information

- Bilateral effusions are more often systemic related transudates (congestive heart failure, renal failure, liver insufficiency, etc.), and advanced imaging is rarely needed. Large unilateral effusions can be malignant. Analysis of fluid may include: cytology, culture, cell count, and biochemical studies.
- PA chest x-ray can show a pleural effusion with approximately 200 ml of pleural fluid while a lateral view can reduce this to 50 ml. Ultrasound is even more sensitive with as little as 3-5 ml of fluid being detected. *Thoracentesis can only be safely performed with adequate fluid present. If only a trace effusion or inadequate amount of fluid is seen, a thoracentesis may not be possible.

Pneumothorax/Hemothorax (CH-19.1)

CH.PT.0019.1.A
v1.0.2026

Chest x-ray and CT Chest are the first line tests for detecting pneumothorax/hemothorax and ruling out other lung diseases.

- Chest x-ray is medically necessary initially.
  - CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250) if:
    - diagnosis of a small pneumothorax is in doubt, and the presence of a pneumothorax will affect individual treatment decisions
    - preoperative study for treatment of pneumothorax
    - pneumothorax associated with hemothorax
    - suspected complications from hemothorax (e.g., empyema)
    - suspected Alpha-1-Antitrypsin Deficiency (even without pneumothorax)
    - suspected cystic lung disease, including lymphangioleiomyomatosis (LAM), tuberous sclerosis (TS), or Birt-Hogg-Dube (BHD) syndrome
    - to determine the etiology of persistent pneumothorax/air leak, such as chest tube malposition, bronchopleural fistula, loculated pneumothorax, lung parenchymal disease
    - suspected catamenial pneumothorax/thoracic endometriosis
- MRI Chest without and with contrast (CPT® 71552) or MRI Chest without contrast (CPT® 71550) for:
  - detecting diaphragmatic endometriosis
  - pre-surgical planning for thoracic endometriosis

Evidence Discussion

The majority of pneumothorax cases can be confirmed by upright PA chest radiography (CR), which remains the standard initial exam.[16] While US has a high sensitivity/specificity for pneumothorax, it is operator-dependent and is not medically necessary as a primary imaging modality.[19-22]

While CT is more sensitive than CR in detecting pneumothorax, it is generally not medically necessary for diagnosis and should be avoided due to excess radiation.[16] CT may be medically necessary for diagnosing a very small pneumothorax or differentiating between a pneumothorax and a giant bulla in bullous emphysema. Although CT is the best method to measure the size of a pneumothorax, current evidence does not support basing treatment decisions solely on size.[14]

The 2001 ACCP guidelines advise against routine CT use for a first-time primary spontaneous pneumothorax (PSP). However, CT may be medically necessary

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

to evaluate suspected pulmonary disorders not apparent on CR. For secondary spontaneous pneumothorax (SSP), CT is acceptable for managing recurrent pneumothorax, persistent air leak, and surgical planning.

In contrast, the 2023 British Thoracic Society recommends CT chest for individuals with symptoms and high-risk characteristics. These include hemodynamic compromise, significant hypoxia, bilateral pneumothorax, underlying lung disease, hemopneumothorax, or age over 49 with a significant smoking history. This recommendation applies if the pneumothorax size on CR is insufficient for safe needle aspiration or chest tube intervention. The European Respiratory Society suggests that CT may be useful in complicated cases, when chest tube misalignment is suspected, when underlying lung disease is suspected, and in individuals requiring surgery.[16]

High-resolution CT (HRCT) has better sensitivity than routine CT in the pre-operative detection of blebs and bullae.[14] However, it is unclear whether HRCT can predict the risk of recurrence or identify which individuals may benefit from surgical intervention. It may help to identify those at lower risk: the positive predictive value of CT bleb scores for ipsilateral recurrence is relatively low at 68%, while the negative predictive value is high at 94%.[15]

Some experts advise considering a CT scan after a first time PSP if there are factors such as a family history of pneumothorax, presence of blebs, cysts, or bullae; female sex; or a family or personal history and/or physical examination findings suggestive of a pneumothorax-associated syndrome.[18]

Although they have low specificity, the most sensitive tests for detecting pneumothorax and hemothorax are CR and CT. For detecting diaphragmatic endometriosis, Magnetic Resonance Imaging (MRI) of the chest is preferable.[5]

Pneumomediastinum; Subcutaneous Emphysema (CH-19.2)

CH.PT.0019.2.A
v1.0.2026

- Chest x-ray is medically necessary initially.
  - CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250) if:
    - recent vomiting and/or suspected esophageal perforation
    - associated pneumopericardium
    - associated pneumothorax
    - preoperative study for treatment

Evidence Discussion

The diagnosis of Pneumomediastinum (PM) is usually established by a clinical exam and CR. The CR should include a lateral view.[8] CR is the most common diagnostic imaging study.[9-11] The reported sensitivity of CR ranges from 60-90%.[9,12] CT is more sensitive than CR, especially in cases of small amounts of air in the mediastinum.[8]

There is no evidence defining when CT should be used to evaluate pneumomediastinum (PM). CT should be done if the suspicion for PM remains high despite a normal CR or if there is concern for secondary PM due to a specific pathologic event.[9]

CT can be beneficial in detecting injury to the tracheobronchial system, pneumothorax, pneumopericardium or esophageal perforation.[12] Despite the usually benign and self-limiting course of spontaneous PM, additional imaging is often undertaken to rule out esophageal perforation or other underlying disorder. A retrospective review of adolescents and young adults with spontaneous PM demonstrated that no clear criteria were used for obtaining a CT and that the CT's did not impact clinical decisions.[13] The authors concluded that advanced imaging is over-utilized in individuals with suspected spontaneous PM without clinical evidence of necessity.

Background and Supporting Information

- An expiration chest x-ray can enhance the evaluation of equivocal plain x-ray. There is no data supporting the use of serial CT Chest to follow individuals with a known pneumothorax, pneumomediastinum, or hemothorax who are asymptomatic or have stable symptoms. With the exception of the indications above, advanced imaging of the chest is not medically necessary in the diagnosis or management of pneumothorax, or pneumomediastinum. Inspiratory/expiratory chest x-rays are helpful in defining whether a pneumothorax is present.

Mediastinal Mass (CH-20.1)

CH.MM.0020.1.A

v1.0.2026

- CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) or MRI Chest without and with contrast (CPT® 71552) or MRI Chest without contrast (CPT® 71550) is medically necessary to evaluate mediastinal abnormalities (e.g., mediastinal cyst, including bronchogenic, thymic, pericardial, or esophageal) seen on chest x-ray or other non-dedicated chest imaging.
- MRI Chest without and with contrast (CPT® 71552) or MRI Chest without contrast (CPT® 71550) is medically necessary for indeterminate mediastinal mass on CT Chest.
  - Surveillance imaging is medically necessary no more frequently than 3-month intervals over 2 or more years when the lesion(s) remain indeterminate on MRI and a biopsy has not been performed.
- FDG PET/CT offers limited additional value beyond that of conventional CT in the initial assessment of mediastinal mass(es), with the exception of primary mediastinal lymphoma. See **Non-Hodgkin Lymphomas (ONC-27)** or **Hodgkin Lymphoma (ONC-28)** in the Oncology Imaging Guidelines. A positive FDG PET/CT has little value for discrimination between benign and malignant lesions. A negative FDG PET/CT does not prevent serial CT/MRIs, due to appreciable false negative rate.
  - MRI Chest without and with contrast (CPT® 71552) or MRI Chest without contrast (CPT® 71550) is medically necessary for indeterminate mediastinal mass on FDG PET/CT.
- CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) or MRI Chest without and with contrast (CPT® 71552) or MRI Chest without contrast (CPT® 71550) is medically necessary for subsequent evaluations if:
  - new signs or symptoms, or
  - preoperative assessment
- For Adenopathy; See **Lymphadenopathy (CH-2).**
- For Goiter; See **Thyroid Nodule (NECK-8.1)** in the Neck Imaging Guidelines.
- For Myasthenia Gravis; See **Neuromuscular Junction Disorders (PN-6.1)** in the Peripheral Nerve Disorders Imaging Guidelines.
- For fibrosing mediastinitis: See **Fungal Infections (Suspected or Known) (CH-14.2)**

Evidence Discussion

Mediastinal nodules or masses may present as incidental findings on chest radiographs and cross-sectional imaging. Alternatively, they may be found during the evaluation of symptoms and signs that include chest pain, cough, dyspnea, dysphagia, cardiac tamponade, diaphragmatic paralysis, central venous thrombosis, superior vena cava

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

syndrome, B-symptoms (in lymphoma), myasthenia gravis, and other paraneoplastic syndromes. The incidence rate is low with a reported prevalence of 0.73-4%. The most frequent lesions encountered in the mediastinum are thymoma, neurogenic tumours and benign cysts.[2]

CT is superior to chest radiography for detection of invasion of the mass across tissue planes, secondary to its higher contrast resolution. Anterior mediastinal tumors account for 50% of all mediastinal masses. CT has the ability to show the precise location, morphology, and pattern of contrast enhancement of an anterior mediastinal mass as well as its relationship to other mediastinal components or borders.[2,6]

MRI remains superior to CT for detection of invasion of the mass across tissue planes, including the chest wall and diaphragm, and involvement of neurovascular structures secondary to its higher soft-tissue contrast. MRI allows further tissue characterization of mediastinal masses beyond that of CT and FDG-PET/CT. Chemical-shift MRI has been shown to be useful in distinguishing normal thymus and thymic hyperplasia from thymic neoplasms and lymphoma. It can also prove the cystic nature of an indeterminate, non–water attenuation thymic mass on CT, preventing unnecessary biopsy and thymectomy. The frequency of surveillance imaging for indeterminate lesions seen on MRI is usually 3-12 month intervals over 2 years or more, depending upon level of clinical concern.[2,4,6] The diagnostic accuracy of chest MRI for the detection of mediastinal mass is 71-91%.[4]

(FDG)-PET/CT offers limited additional value beyond that of conventional CT in the initial assessment of mediastinal masses, with the exception of its use for primary mediastinal lymphoma staging and surveillance and detection of metastatic lymphadenopathy. A positive FDG-PET/CT has little value for discrimination between benign and malignant lesions.[2,3,5,6]

It is reasonable to perform a chest radiograph as an initial imaging step. Chest radiography can help localize a mass to a specific mediastinal compartment and thereby narrow the differential diagnosis. Chest radiography offers limited assistance regarding tissue characterization of mediastinal masses, with the exception of its occasional demonstration of calcium within a lesion.[2]

There is little relevant literature to support the use of ultrasound (US) in the initial evaluation of a clinically suspected mediastinal mass.[2]

Fibrosing mediastinitis (FM) is a rare benign but potentially life threatening process characterized by progressive proliferation of dense infiltrative fibrous tissue in the mediastinum and/or hila. Granulomatous FM is the more common subtype in the US and is typically associated with prior infection with histoplasmosis. Nongranulomatous FM is less common and is usually associated with an autoimmune disorder, drug exposure, or prior radiation. The most common symptoms are cough, dyspnea, hemoptysis, and pleuritic chest pain. Individuals may develop SVC syndrome or post-obstructive pneumonia. Widening of the mediastinum and mediastinal/hilar

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

lymphadenopathy are the most common abnormal findings on chest x-ray. CT chest with contrast is the modality of choice for suspected FM. MRI is equivalent to CT for evaluating extent of disease, but CT is superior for evaluation of airways and calcification. PET CT is nonspecific and not routinely used. Nonsurgical and surgical procedures for individuals with clinical symptoms are related to compression or obstruction of mediastinal structures. CTA chest may be used for procedural planning or to evaluate the patency of vascular stents. There are no consensus guidelines for follow up imaging. No routine imaging is medically necessary for the granulomatous subtype unless there are progressive symptoms or clinical decompensation. Regular surveillance with CT is recommended for the nongranulomatous subtype to rule out malignancy which may not have been sampled in a biopsy.[7]

Chest Trauma (CH-21.1)

CH.CT.0021.1.A
v1.0.2026

- Chest x-ray is medically necessary initially.
  - CT Chest without contrast (CPT® 71250) or with contrast (CPT® 71260) is medically necessary for the following situations:
    - Rib or sternal Fracture when clinical findings or other imaging identifies associated complications including pneumothorax, hemothorax, pulmonary contusion, atelectasis, flail chest, cardiovascular injury and/or injuries to solid or hollow abdominal organs.
    - Rib or sternal facture when malignancy is suspected as the etiology for uncomplicated, single fractures, multiple fractures, non-acute fractures, or occult rib fractures that are identified on x-ray.
    - Routine follow-up advanced imaging of rib or sternal fractures is not medically necessary.
- CT Chest without contrast (CPT® 71250) or Tc-99m bone scan whole body (CPT® 78306) is medically necessary for suspected pathological rib fractures, with or without a history of trauma
- For clavicle fractures and sterno-clavicular (SC) dislocation, see **Joint Instability and Dysfunction (MS-30.0)**.
- Advanced imaging of the abdomen or pelvis is not medically necessary for chest trauma when there is no physical examination or laboratory evidence of abdominal and/or pelvic injury.

Evidence Discussion

- Chest x-ray, in combination with physical exam, is the appropriate initial diagnostic modality in those with suspected rib or sternal fracture after chest trauma. Although chest x-ray has low sensitivity (approximately 50%) for detection of rib fracture,[1] it has the benefit of being widely and readily available and able to detect complications that may require additional imaging such as pneumo- or hemothorax and pulmonary contusions.[1,2] In addition, failure to detect rib fractures in uncomplicated cases does not significantly alter the individual management or outcomes. A study by Bansidhar et al. showed no difference in treatment in individual with minor chest trauma who did and did not have rib fractures diagnosed either clinically or radiographically.[1] Therefore, in uncomplicated cases, additional advanced imaging is not medically necessary. Rodriguez et al. demonstrated that yield for CT of thoracic injury with major clinical significance after a normal chest x-ray is 1.5% and would only detect one major injury for every 67 studies.[3]

Click Here to Return to the Main TOC

- In cases where complications are identified clinically or by other imaging, additional imaging with CT chest is medically necessary. CT does have higher sensitivity for detection of rib fractures[1] and in the detection and extent of pulmonary injuries.[2] It also may be useful in differentiating blunt cardiac injury from acute myocardial infarction. However, CT does carry with it the risk of contrast related renal injury and allergic reactions.[3] It also exposes the individual to a greater amount of ionizing radiation than a chest x-ray and subsequent increased risk of induced cancers.[3] It is estimated that undergoing chest CT will result in one radiation induced cancer per every 720 40-year-old females and 1,538 40-year-old males.[3]
- If a pathological rib fracture is suspected, imaging with either a CT chest or Tc-99m bone scan is medically necessary. CT may be helpful in differentiating primary tumor from metastasis and may aid in detection of the primary malignancy.[1] Tc-99mm bone scan has low specificity but high sensitivity (>95%) for detection of pathologic rib fractures.[1]
- Medial clavicular fractures are rare (<5% of cases) and may necessitate additional imaging with CT or MRI for evaluation.[4] Midshaft and distal clavicular fractures are usually sufficiently evaluated by x-ray.[4]
- Chest x-ray has poor sensitivity for identification of sternoclavicular dislocations. Given the risk for complications such as pneumothorax in posterior displacement, advanced imaging may be medically necessary. CT is advantageous as it has superior image resolution. It also allows for 3D reconstruction to determine exact position of the sternoclavicular joint. MRI can also be utilized but it has poorer resolution than CT. However, it may be advantageous for evaluation of soft tissue conditions or ligamentous injury.[5]
- For isolated chest injury without signs or symptoms of abdominal or pelvic injury, advanced imaging of the abdomen or pelvis is not medically necessary. If abdominal or pelvic injury is suspected, imaging is as dictated elsewhere in these guidelines.

Chest Wall Mass (CH-22.1)

CH.CM.0022.1.A
v1.0.2026

- Chest x-ray is useful in the workup of a soft-tissue mass and is almost always medically necessary as the initial imaging study.
  - Chest ultrasound (CPT® 76604) is medically necessary as an initial imaging study in the setting of a suspected superficial or subcutaneous lipoma. This modality may also be valuable in differentiating cystic from solid lesions and has also been used to assess the vascularity of lesions.
  - Following a non-diagnostic chest x-ray that does not show an obvious lipoma(s) or clearly benign entity (see **Tissue Growths and Masses (MS-10)** in the Musculoskeletal Imaging Guidelines), ONE of the following is medically necessary:
    - MRI Chest without and with contrast (CPT® 71552) or
    - MRI Chest without contrast (CPT® 71550) or when MRI is contraindicated,
    - CT Chest with contrast (CPT® 71260) or
    - CT Chest without contrast (CPT® 71250)

Evidence Discussion

Radiography is medically necessary as the initial imaging study for both superficial and non-superficial soft tissue masses. Radiography can help identify calcifications, bone involvement, intrinsic fat, and unsuspected skeletal abnormality or deformity. In general, radiographic findings related to a soft tissue mass can provide helpful insight in determining the next most appropriate imaging modality for further characterization.[1-5] Non-contrast enhanced ultrasound is also an excellent triage tool for evaluating superficial soft tissue masses like superficial lipomas.[1,3-5] However, ultrasound is not sufficient to assess for malignancy. When features detected on ultrasound are not clearly benign or when findings are concerning, further advanced imaging is medically necessary.[1]

MRI without and with IV contrast is medically necessary as the next imaging study for a soft tissue mass following non-diagnostic radiographs.[1-4]

MRI helps to define intrinsic tumor characterization, vascular structures, neurovascular involvement, hemorrhage, edema, and tumor necrosis. MRI without IV contrast may be beneficial compared with CT, but the use of MR contrast improves the differentiation of benign from malignant soft tissue masses.[1-4] At least 20% to 25% of soft tissue masses can demonstrate features that allow for confident diagnosis based on MRI alone, many of which are benign and thus would not warrant biopsy.[1,3,4] MRI has a sensitivity of 96%, a specificity of 72%, a positive predictive value of 77%, a negative predictive value of 83%, and a diagnostic accuracy of 88%.[6]

Click Here to Return to the Main TOC

When MRI is contraindicated, CT with IV contrast is medically necessary following non-diagnostic radiograph.

CT with IV contrast is useful in distinguishing vascularized from potentially necrotic regions of a tumor or calcification.[1-4]

Background and Supporting Information

- Chest x-rays of chest wall masses can detect calcification, ossification, or bone destruction as well as location and size.

Pectus Excavatum and Carinatum (CH-23.1)

CH.EC.0023.1.U

v1.0.2026

- CT Chest without contrast (CPT® 71250) or MRI Chest without and with contrast (CPT® 71552) and 3-D reconstruction (CPT® 76377 or CPT® 76376) if:
  - Candidates for surgical correction.
  - Cardiac or pulmonary dysfunction has been identified
    - ECG and echocardiography if cardiac symptoms or evidence of cardiac function abnormalities.
    - Chest x-ray and PFT's if increasing shortness of breath.

Background and Supporting Information

- Chest measurements derived from CT Chest, such as the Haller Index or the correction index, are helpful to the thoracic surgeon in pre-operative assessment of chest wall deformities to assess for the appropriateness of operative repair prior to the development of symptomatic pectus deformities.
- The Haller index is calculated using the width of the chest divided by the distance between the posterior surface of the sternum and the anterior surface of the spine. A Haller index score is normal at 2.5 to 2.7 and severe at 3.25 or greater. The correction index uses an equation of (b−a)/b×100, in which a is the minimum distance between the anterior spine and the posterior surface of the sternum, and b is the maximum distance between the anterior spine and most anterior internal rib. It yields a percentage that the chest would need to be corrected to achieve normal dimensions, with a normal level being 10% or less.
- Some have suggested that a CXR can replace the CT Chest for Haller Index calculation with a strong correlation and high diagnostic accuracy.
- Expert consensus from The Society of Thoracic Surgeons 2023 recommended that a comprehensive evaluation with spirometry, ECG, and echocardiography be done with any cardio-pulmonary complaint. The Haller index, correction index, pulmonary compression or failed previous repair, in and of itself, was not an indication for surgery. Corrective surgery indications for those with severe pectus excavatum included: progression of deformity, presence of cardio-pulmonary symptoms, mitral valve prolapse, arrhythmia, significant body image disturbances, abnormal PFTs, abnormal cardiac function test, or the presence of cardiac compression on imaging (echo or CT).

Pulmonary AVM (CH-24.1)

CH.AV.0024.1.A

v1.0.2026

- CT Chest with contrast (CPT® 71260), CT Chest without contrast (CPT® 71250), CTA Chest (preferred modality for pre-intervention planning) (CPT® 71275), or MRA Chest (CPT® 71555) for evaluation of:
  - suspected pulmonary AVM, including individuals with HHT (Hereditary Hemorrhagic Telangiectasia) or who have a first degree relative with HHT
  - first degree relatives of an individual with a primary pulmonary AVM
  - evaluation of individuals with paradoxical embolus/stroke and no evidence of patent foramen ovale on echocardiogram
  - follow-up of treated AVM's at 6 months post embolization and then every 3-5 years
  - follow-up of untreated AVM's to be determined by treating physician but no more than annually. Usually the interval is 3-5 years due to the slow-growth nature of PAVM's
  - treated or untreated PAVM's with recurrent symptoms

Evidence Discussion

Chest x-ray is the most appropriate initial imaging exam with presentation of hypoxemia or hemoptysis but it does have low sensitivity for pulmonary arteriovenous malformation (PAVM).[3]

CT chest is the test of choice for diagnosing a PAVM. Contrast may be considered for an atypical nodule/soft tissue lesion on CT chest without contrast and suspicion for a PAVM. CTA chest is the gold standard for defining the vascular anatomy of a previously identified PAVM. It is not routinely used for diagnosis except in the setting of concomitant embolization therapy, diagnostic uncertainty, or pre-intervention planning.[3] MRA chest avoids ionizing radiation but is not as sensitive or specific as CT for the diagnosis of PAVM and has limitations detecting PAVM <5mm.[3] It has a potential role in younger people with Hereditary Hemorrhagic Telangiectasia (HHT) who may require lifelong surveillance.[3]

CT chest without contrast may be done to screen for PAVM in people with possible or confirmed Hereditary Hemorrhagic Telangiectasia (HHT).[1] A negative CT chest with or without contrast helps to exclude a clinically significant PAVM.[2]

Background and Supporting Information

- Pulmonary AVMs are abnormal connections between pulmonary arteries and veins, usually found in the lower lobes, that can be either primary (such as in individuals with HHT) or acquired (such as trauma, bronchiectasis). They can be identified in up to

Pulmonary Embolism (CH-25.1)

CH.PE.0025.1.A
v1.0.2026

- CT Chest with contrast with PE protocol (CPT® 71260) or CTA Chest (CPT® 71275) is medically necessary if at least one symptom, clinical/laboratory finding, or risk factor from each of the lists below are present.
  - With any ONE of the 3:
    - Dyspnea, new onset and otherwise unexplained;
    - Chest pain, pleuritic;
    - Tachypnea
  - AND, with any ONE of the 3:
    - Abnormal **D-dimer** test;
    - Wells Criteria score* higher than 4 points;
    - One risk factor** or symptom** of new onset demonstrating high clinical probability of PE

RISK FACTORS**	SYMPTOMS ATTRIBUTED TO PE**
Immobilization via hospitalization or institutional care at least 3 days or surgery in last 4 weeks or recent trauma	Signs or symptoms of DVT
Previous history of DVT or PE	Hemoptysis
Cancer actively treated in last 6 months or receiving palliative treatment or myeloproliferative disorder	Right heart strain or failure
Recent history of a long airplane flight	Systolic BP <90
Use of estrogen-based contraceptives (birth control pills), oral estrogen	Syncope
Advanced age (≥70)	Cough
Congestive heart failure, congenital heart disease, hypertension, superficial venous thrombosis, and/or indwelling central vein catheter	Heart Rate >100

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

RISK FACTORS**	SYMPTOMS ATTRIBUTED TO PE**
Obesity (BMI ≥30)	Palpitations
COVID-19 for those post-hospitalization or those within 30 days of diagnosis	
Recurrent pregnancy loss	
COPD	
Thrombotic disorders, antiphospholipid antibody syndrome, and/or autoimmune disease	
Inflammatory bowel disease	
Nephrotic syndrome	
In vitro fertilization (IVF) treatment	

Well's Criteria for Clinical Probability of PE*	
Clinical signs/symptoms of DVT (at minimum: leg swelling and pain with palpation of the deep veins)	3
PE is likely or equally likely diagnosis	3
Heart rate >100	1.5
Immobilization at least 3 days or surgery in last 4 weeks	1.5
Previous history of DVT or PE	1.5
Hemoptysis	1
Cancer actively treated in last 6 months or receiving palliative treatment	1
Calculate Probability: Low <2 Moderate 2 to 6 High >6	

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Well's Criteria for Clinical Probability of PE*
Using the above criteria, only 3% of individuals with a low pretest probability had PE versus 63% of those with a high pretest probability.

- Non-urgent cases which do not meet above 2-step criteria, should undergo prior to advanced imaging:
  - Chest x-ray (to rule out other causes of acute chest pain)
  - Primary cardiac and pulmonary etiologies should be eliminated
- Pregnancy is a risk factor for thrombo-embolic events in and of itself. Additional risk factors are not required. Pregnant individuals with suspected PE should proceed with:
  - If signs/symptoms of DVT are present, Doppler studies of the lower extremities (CPT® 93970 bilateral study or CPT® 93971 unilateral study) are medically necessary
  - If no signs/symptoms of DVT, then chest x-ray first.
  - If chest x-ray is normal, then V/Q scan (CPT® 78580 or CPT® 78582) (preferred test), or CTA Chest (CPT® 71275) or CT Chest with contrast with PE protocol (CPT® 71260)
  - If chest x-ray is abnormal or after non-diagnostic V/Q scan or if V/Q scanning is not readily available, then CTA Chest (CPT® 71275) or CT Chest with contrast with PE protocol (CPT® 71260).
- Ventilation-perfusion scans, also called V/Q, scans (CPT® 78580-Pulmonary Perfusion Imaging; CPT® 78582-Pulmonary Ventilation (e.g., Aerosol or Gas) and Perfusion Imaging) or SPECT/CT (CPT® 78830):
  - Is not a replacement for CTA Chest
  - Is medically necessary in any of the following:
    - Suspected pulmonary embolism if there is a contraindication to CT or CTA Chest (ventilation-perfusion scans CPT® 78582)
    - Suspected pulmonary embolism when a chest x-ray is negative and CTA Chest is not diagnostic (CPT® 78580 or CPT® 78582)
    - Follow-up of an equivocal or positive ventilation-perfusion lung scan to evaluate for interval change (CPT® 78580)
    - Suspected Chronic thromboembolic disease or Chronic thromboembolic pulmonary hypertension*, usually after 3 months of effective anticoagulation
- Follow-up imaging in stable or asymptomatic individuals with known PE is not medically necessary
- Follow-up imaging with CT Chest with contrast with PE protocol (CPT® 71260) or CTA Chest (CPT® 71275) for ANY of the following indications:
  - Recurrent or persistent signs or symptoms such as dyspnea, or
  - Elevated D-dimer which is persistent or recurrently elevated, or

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

  - Right heart strain or failure identified by EKG, ECHO or heart catheterization
- For Pulmonary Artery Hypertension (PAH), see **Pulmonary Artery Hypertension (PAH) – Indications (CD-8.1)** in the Cardiac Imaging Guidelines.

Evidence Discussion

Symptoms and signs of pulmonary embolus (PE) are nonspecific and common; therefore, knowing whom to test for PE is challenging.[9] In North America, PE is diagnosed in only 5% of people tested for it.[8] Chest x-ray (CR) is nonspecific but may rule out other causes of dyspnea and chest pain. Avoiding the overuse of imaging tests is important, given the potential harms of radiation exposure, high costs and complications. The pretest clinical probability has an important effect on the predictive value of CT pulmonary angiography (CTPA).[8] Determining the clinical pretest probability of PE depends on clinical judgment, which lacks standardization and is subjective, or prediction rules.[8,11] Kahn et al recommend diagnostic imaging in those with a likelihood of PE greater than or equal to 15%, based on the "implicit sense" of the clinician, and either a structured clinical probability score (Wells, Revised or Simplified Geneva score) or a D-dimer above a pre-specified threshold.[9] Other experts recommend that imaging be done in those with a high pretest probability based on empirical clinical judgment or a prediction rule and in those with a low/intermediate pretest probability and a positive D-dimer.[8,10] Imaging can be avoided in people with both a structured clinical probability score at or below the given cutoff and a D-dimer below the given cutoff value.[9] Imaging is likewise not medically necessary in those with a low/intermediate pretest probability based on clinical judgement and a normal D-dimer.[8,10]

CTPA is highly sensitive and specific and is the imaging method of choice for suspected PE.[8-11] It may also demonstrate other potential causes of the presenting symptoms. CTPA is a CT angiogram with intravenous (IV) contrast. The timing of the scan is tailored so that contrast enhances the pulmonary arterial system to identify potential filling defects. CT with contrast is usually not medically necessary. According to the American College of Radiology, when IV contrast is given during CT acquisition for suspected PE, the study should be performed as a CTPA.[10]

Planar V/Q may preferentially be used in outpatients with a low clinical probability of PE and normal CR, in young (especially female) individuals, pregnant women, and individuals with a history of contrast allergy or renal failure.[8] The proportion of diagnostic V/Q scans is higher in individuals with a normal CXR. A normal V/Q scan has a high negative predictive value, but there is a high proportion of non-diagnostic scans and it cannot provide alternative diagnoses.[10] Abnormal regional lung perfusion may suggest PE but is not specific and requires correlation with ventilation studies or other imaging. Investigators have studied single-photon emission CT (SPECT) to improve the sensitivity and specificity of V/Q scans. Kahn et al state that V/Q SPECT is a low radiation option to minimize lung and breast tissue irradiation in younger individuals.[9] Some authors believe that V/Q SPECT should be the preferred study in the evaluation

Click Here to Return to the Main TOC

of suspected PE.[12] However, large scale prospective trials are needed to validate SPECT techniques before its widespread incorporation into diagnostic algorithms.[8] SPECT has over 90% sensitivity and 72-98% specificity, and V/Q SPECT/CT has the highest diagnostic accuracy.[16-18]

A normal perfusion scan and a negative CTPA appear equally safe for ruling out PE in pregnancy.[8] There is debate regarding which is the first test of choice. CTPA is more expensive and exposes the pregnant woman to more radiation than the fetus; V/Q scans have low radiation and no contrast-related side effects.[13] A compression duplex ultrasound of the lower extremity is medically necessary if there are symptoms/signs of a DVT. If a DVT is diagnosed, anticoagulation can be administered without further imaging. A CXR is medically necessary. An alternative diagnosis may be found, and it can inform the choice between CTPA and a V/Q scan as the next test when there is no clinical evidence of a DVT.[10] If there is no DVT and a CXR is normal, CTPA or a perfusion scan is medically necessary. If the perfusion scan is normal, a ventilation scan may not be needed. If the CXR is abnormal, alternative causes have been considered and PE is still suspected, CTPA is medically necessary.[8]

Acute PE is treated for at least 3 months with anticoagulation. Individuals should have a follow-up visit 2 weeks to 3 months after PE. If symptoms worsen or the diagnosis is complex, follow-up may occur sooner.[6] Whether anticoagulation is stopped after 3 months or continued indefinitely depends on whether the reduced risk of recurrent venous thromboembolism (VTE) outweighs the increased risk of bleeding.[8] The risk of recurrent VTE after stopping anticoagulation is related to the risk factor category for the index PE/VTE event. There are many genetic and acquired risk factors for VTE associated with a low, intermediate or high risk of recurrence.[8,11]

Patency of the pulmonary arterial bed is restored in the majority of people within the first few months, and routine CTPA imaging is not medically necessary.[8] Konstantinides et al recommend a transthoracic echocardiogram in those with dyspnea or functional limitation at follow up.[8] If the probability of pulmonary hypertension is felt to be high, planar V/Q is considered the first line imaging test for suspected chronic thromboembolic pulmonary hypertension (CTEPH). CTPA should not be used as a stand alone test to rule out CTEPH. The diagnosis is based upon measurements made during right heart catheterization and mismatched perfusion defects on V/Q scan more than 3 months after an acute PE.[8]

Background and Supporting Information

- Pulmonary embolism is found in approximately 10% of all those that present with suspicion of PE. Dyspnea, pleuritic chest pain, and tachypnea occur with about 50% incidence with leg swelling or pain just over 50%.
- D-dimer level has a high sensitivity and low specificity for diagnosing PE.
  - A negative D-dimer in combination with low or moderate PE risk classification has a negative predictive value approaching 100%.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

  - D-dimer can be falsely elevated with surgery, injury, malignancy, sepsis, diabetes, pregnancy, or other conditions where fibrin products are likely to be present.
- CT imaging has supplanted V/Q scanning since the latter is difficult to obtain quickly, does not provide a substantial cost savings, and does not diagnose other pulmonary pathology.
- The decision to terminate anticoagulation treatment after previous pulmonary embolism (PE) with absent or stable symptoms is based on clinical evaluation and risk factors.
- Repeat studies do not allow one the ability to distinguish new from residual clot, with luminal diameter and clot character poorly correlated to symptoms and ECHO findings.
- Half to two thirds of individuals with primary thromboembolism have residual pulmonary artery clot at 6 months and 50% remain at one year, depending on modality at follow-up.
- Subsequent persistence or elevation of D-dimer is associated with increased risk of recurrent PE. ECHO and Right Heart Catheterization (RHC) can identify those with pulmonary hypertension. Yet, 1/2 of all have persistent or new pulmonary hypertension after primary thromboembolism and only half of this latter group has dyspnea at rest or exercise intolerance.
- Of note, pregnancy is accompanied by a progressive increase in D-dimer levels, and as such, D-Dimer levels may not be helpful to rule-in or rule-out DVT/PE in pregnancy.

Modality	Fetal radiation exposure in mGy
CXR	0.002-0.1
V/Q	0.32 – 0.74
CTPA	0.03 – 0.66

- Compared with V/Q scan, computed tomography pulmonary angiography (CTPA) is associated with a higher radiation dose to the mother: the calculated doses to breast and lung tissue have been estimated to range from 10mGy to 60mGy and 39.5mGy, respectively, with CTPA ,as compared with 0.98mGy to 1.07mGy and 5.7mGy to 13.5mGy, respectively, with V/Q scan.

Pulmonary Embolism Health Equity Considerations

- Black individuals and female individuals have a higher risk of pulmonary embolism.

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Underrepresented racial/ethnic groups are less likely to undergo advanced therapies for pulmonary embolism.
- Several risk factors for pulmonary embolism (e.g., hyperestrogenic state due to oral contraceptives, pregnancy, or HRT) are exclusive to female individuals.
- Individuals with a low socioeconomic status have reduced access to high-quality imaging centers and undergo fewer advanced interventions for pulmonary embolism.

Elevated Hemidiaphragm (CH-30.1)

CH.EH.0030.1.A
v1.0.2026

- CT Chest with contrast (CPT® 71260) and/or CT Neck with contrast (CPT® 70491) with new diaphragmatic paralysis after:
  - previous chest x-rays are available and reviewed to determine if the diaphragmatic elevation is a new finding, and/or
  - fluoroscopic examination ("sniff test") to differentiate true paralysis from weakness
- CT Abdomen with contrast (CPT® 74160) to rule out liver or abdominal process if CT Chest is negative.
- Repeat advanced imaging studies in the absence of new signs or symptoms are not medically necessary.

Evidence Discussion

Diaphragmatic dysfunction includes eventration, weakness and paralysis. Diagnosis is based in part on static and dynamic imaging tests.[1] Unilateral diaphragmatic paralysis is often asymptomatic and suspected when an elevated hemidiaphragm is found incidentally on chest x-ray (CR). CR is a simple and effective test to evaluate the pulmonary parenchyma and the diaphragm.[1] CR has a sensitivity of 66.6% and a specificity of 44%.[4] The positive and negative predictive value of an elevated hemidiaphragm on CR for diaphragmatic dysfunction is 33% and 93%, respectively. The presence of diaphragm elevation is not necessarily a sign of dysfunction, but its absence makes it unlikely.[1]

Flouroscopy has traditionally been the gold standard for diagnosing diaphragmatic paralysis since it can visualize the diaphragm throughout the respiratory cycle and during forced inspiratory maneuvers (i.e., the "sniff test"). Some authors now consider US to be the imaging method of choice for the evaluation of diaphragmatic dysfunction.[1,2] US is non-invasive, portable, quick and does not expose the individual to ionizing radiation. Absence of thickening of the diaphragm during inspiration, absence of caudal movement during normal inspiration or paradoxical movement during the sniff maneuver confirms paralysis.[4]

A common concern is whether there is an underlying serious condition in those individuals with unilateral hemidiaphragm paralysis with no evident etiology after a history, physical exam and CR. Piehler et al concluded that such individuals are unlikely to have an underlying occult malignant or neurologic condition.[3] However, Windisch et al recommended that a one-time CT chest be done if there is clinical suspicion of possible malignancy with damage to the phrenic nerve.[2]

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Additional imaging may be needed to rule out conditions which can cause an elevated hemidiaphragm but are not associated with respiratory muscle weakness. For example, abdominal imaging can be done for suspected hepatic abscess, ascites, or splenomegaly.

Background and Supporting Information

- The right hemidiaphragm sits about 2cm higher than the left.
- “Eventration” is thin membranous replacement of muscle, usually on the right, as the most common cause of elevation.
- Any injury to the phrenic nerve from neck to diaphragm can lead to paralysis.
- Common phrenic causes are traumatic or surgical injury or malignancy involving the mediastinum.
- Any loss of lung volume or increased abdominal pressure can lead to diaphragm elevation.

Pre-Transplant Imaging Studies (CH-32.1)

CH.LT.0032.1.A
v1.0.2026

- Individuals on the waiting list or being considered for the lung transplant can undergo advanced imaging per that institution's protocol, or any of the studies listed below are medically necessary:
  - CT Chest with and without contrast (CPT® 71270), CT Chest with contrast (CPT® 71260), or CT Chest without contrast (CPT® 71250)
  - ECHO
  - Imaging Stress Test (MPI, SE, MRI) or Heart Catheterization (Right and Left); Heart catheterization can also be done after a positive stress test.
  - CTA Chest (CPT® 71275), and/or CTA Abdomen and Pelvis (CPT® 74174) and/or CTA Aorta with bilateral lower extremity run-off (CPT® 75635) is medically necessary (without initial ABI's and/or arterial duplex) for the following individuals:
    - prior abdominal or lower extremity vascular intervention (any timeframe is acceptable)
    - known peripheral artery disease (PAD) from prior imaging
    - current symptoms of claudication, rest pain or gangrene
  - CTA Chest (CPT® 71275) and/or CTA Abdomen and Pelvis (CPT® 74174) and/or CTA Aorta with bilateral lower extremity run-off (CPT® 75635) is medically necessary (after initial ABI's and/or arterial duplex) for the following individuals:
    - Initial ABI's and/or arterial duplex suggest the presence of PAD as evidenced by one of the following:
      - ABI of <0.9
      - presence of plaque
      - presence of vascular calcification, stenosis or occlusion
      - small vessel size on the duplex
  - CT Abdomen and Pelvis with or without contrast (CPT® 74177 or CPT® 74176) for determining extracorporeal membrane oxygenation (ECMO) candidacy
- Other studies that are medically necessary include V/Q scan and Six Minute Walk Test.
- See **Transplant (CD-1.6)** in the Cardiac Imaging Guidelines.

Evidence Discussion

- Computed Tomography (CT) is often performed for evaluation of individuals prior to lung transplantation. CT allows for surgical planning to delineate extent of the disease

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

and assess for any contraindications to transplant.[6] CT carries the risk of exposure to iodinated contrast and ionizing radiation.

- Evaluation of donors is commonly performed by chest radiography.[6,8] Occasionally, evaluation of donors is performed by chest CT to assess for malignancy, pneumonia, emphysema, and other diseases.[9]
- Cardiac evaluation with echo and/or ischemic evaluation (image stress testing or heart catheterization) is medically necessary prior to lung transplantation.
- Extracorporeal Membrane Oxygenation (ECMO) has been increasingly utilized for bridging prior to lung transplantation or as an adjunct procedure post-transplant.[4,5] Given the risk of vascular complications,[3] preoperative evaluation of the vasculature is reasonable. For those that are asymptomatic without previously known peripheral artery disease (PAD), initial work up with ankle-brachial index (ABI) and/or arterial duplex is medically necessary.[7] For those that are symptomatic, have a history of known PAD (either from prior imaging or previous vascular intervention) or initial work up has suggested the presence of PAD, advanced imaging is medically necessary for further evaluation.[7]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Post-Transplant Imaging Studies (CH-32.2)

CH.LT.0032.2.A

v1.0.2026

- CT Chest with and without contrast (CPT® 71270), CT Chest with contrast (CPT® 71260), or CT Chest without contrast (CPT® 71250) is medically necessary for:
  - initial post-transplant follow-up
  - suspected complication, either surgical, medical or infectious, (See **Background and Supporting Information**)
  - worsening PFT's
  - new finding on other imaging, including chest x-ray
- CTA chest (CPT® 71275) is medically necessary for suspected torsion
- See **Transplant (CD-1.6)** in the Cardiac Imaging Guidelines.

Evidence Discussion

- There are no universally accepted follow-up protocols for routine post-transplant surveillance.[6] CT chest is supported for initial post-transplant follow up.[1,6] CT carries with it the risk of exposure to iodinated contrast and ionizing radiation.[8,9]
- Additional follow-up is based on clinical presentation, suspected complication, or findings on other imaging.[1,6]

Background and Supporting Information

- Complications from lung transplantation are a major cause of morbidity and mortality.
- The three main categories of complications are surgical, medical and infectious.
  - Surgical complications include: anastomotic complications, bronchial dehiscence, bronchial stenosis, pneumothorax, hemothorax, hematoma, wound dehiscence, and infection.
  - Medical complications include: primary graft dysfunction, pulmonary embolism and pulmonary infarction, Tracheobronchomalacia, posttransplant lymphoproliferative disease, primary disease recurrence, and acute and chronic allograft rejection, including bronchiolitis obliterans and restrictive allograft syndrome.
  - Infectious complications include: hospital and community acquired nonmycobacterial pulmonary infections, mycobacterial infections, fungal infections, and viral infections (CMV most common).

Lung Transplant Health Equity Considerations

- The majority of individuals who receive lung transplants in the United States are of White race and are male. Compared to a matched person of another gender or race, these individuals have a higher likelihood or being allocated a lung transplant.

U.S. Preventive Services Task Force: Lung Cancer Screening (CH-33.1)

CH.CS.0033.1.A
v1.0.2026

- Low-dose CT Chest (CPT® 71271) for lung cancer screening in asymptomatic individuals* annually when all of the following criteria have been met:

Screening Indications	Imaging Study
• All criteria below must be met: ◦ Individual has not received a low-dose CT lung screening in less than 12 months; and ◦ Individual has NO health problems that substantially limit life expectancy or the ability or willingness to have curative lung surgery**; and ◦ Individual is between 50 and 80 years of age; and ◦ Individual has at least a 20 pack-year history of cigarette smoking; and ◦ Currently smokes or quit within the past ≤15 years	Low-Dose CT Chest without contrast (CPT® 71271)

For those that no longer qualify for annual LDCT for lung cancer screening but have known lung nodules, follow criteria for follow-up under CH-16. For example, a nodule that is new on the last screening LDCT may warrant continued diagnostic CT evaluation per CH-16.2.

*Symptoms of lung cancer (e.g., hemoptysis, unexplained cough, and/or unexplained weight loss of >15 pounds in the past year) warrant diagnostic evaluation, not screening.

**This is based on a range of chest or other organ signs, symptoms or conditions which would question the member's ability to undergo surgical or non-surgical treatment if a lung cancer was discovered. For example, congestive heart failure, advanced cancer from another site or a member with COPD who uses oxygen when ambulating, would be examples of conditions that would "substantially limit life expectancy." Conversely, stable COPD and its symptoms, including cough, shortness of breath would not "substantially limit life expectancy."

Lung Cancer Screening Health Equity Considerations

- Black men, individuals with lower levels of education, and individuals with lower household income levels are less likely to be eligible for screening.
- Among individuals who are eligible for lung cancer screenings, Black individuals and those with a lower socioeconomic status are screened at a lower rate and have lower adherence to screening follow-up. This could be attributed to differences in referral rates among providers.
- Barriers to lung cancer screenings include:
  - Individual-level barriers, such as limited knowledge about screening, lack of education and recommendations from providers, distrust of the medical system, and lack of transportation
  - Provider-level barriers, such as lack of knowledge about screening recommendations and lack of time for shared decision-making
  - System-level barriers, such as misconceptions about screening requirements, lack of scanners, limited resources, and low reimbursement rates

Incidental Pulmonary Nodules Detected on Low Dose CT Chest (LDCT) Images (CH-33.3)

CH.CS.0033.3.A

v1.0.2026

- Any Lung-RADS requiring less than 1 year interval follow-up is coded as Low-Dose CT Chest (CPT® 71250) (Not CPT® 71271 which is ONLY the annual screen)
- For lung nodules, including incidental findings from studies other than screening LDCT, or if no longer qualify for screening LDCT, see **Incidental Pulmonary Nodules Detected on CT Images (CH-16.2).**

Lung-RADS Primary Category/ Category Descriptor	Management
0: Incomplete	If findings suggestive of an inflammatory or infectious process, follow-up with LDCT (CPT® 71250) in 1-3 months
1: Negative - very low likelihood of becoming a clinically active cancer	Annual LDCT screening (CPT® 71271) in 12 months
2: Benign appearance or behavior - very low likelihood of becoming a clinically active cancer due to size or lack of growth	Annual LDCT screening (CPT® 71271) in 12 months
3: Probably benign finding(s) - short term follow-up suggested; includes nodules with a low likelihood of becoming a clinically active cancer	6 month LDCT (CPT® 71250) and if unchanged on this CT it is coded as category 2 and returned to annual LDCT screening (CPT® 71271) in 12 months

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Lung-RADS Primary Category/ Category Descriptor	Management
4A: Suspicious - Findings for which additional diagnostic testing and/ or tissue sampling is recommended	PET/CT (CPT® 78815) when there is a ≥8 mm solid nodule or solid-component Follow-up with LDCT (CPT® 71250) in 3 months and if stable or decreased in size on this CT, it is coded as category 3 with follow-up LDCT (CPT® 71250) at 6 months, if stable or decreased in size on this CT, return to annual LDCT screening (CPT® 71271) in 12 months
4B or 4X: Suspicious - Findings for which additional diagnostic testing and/ or tissue sampling is recommended	CT Chest with or without contrast, PET/ CT (CPT® 78815), and/or tissue sampling depending on the probability of malignancy and comorbidities. PET/CT (CPT® 78815) when there is a ≥8 mm solid component. If there is low suspicion of lung cancer, follow-up with LDCT (CPT® 71250) in 3 months with another LDCT (CPT® 71250) in 6 months and if unchanged on this CT return to annual LDCT screening (CPT® 71271) in 12 months

For those that no longer qualify for annual LDCT for lung cancer screening but have known lung nodules, see criteria for follow-up under CH-16. For example, a nodule that is new on the last screening LDCT may warrant continued diagnostic CT evaluation per **CH-16.2**.

Evidence Discussion

- Low-dose computed tomography (LDCT) Chest for lung cancer screening has been shown to have sensitivity ranging from 59% to 100%, a specificity of 26.4% to 99.7%, a negative predictive value of 97.7% to 100% and a positive predictive value from 3.3% to 43.5%.[2] The benefit of lung cancer screening is early detection and treatment. The NLST trial showed a relative risk reduction in lung cancer mortality of 20%.[2] The radiation dose of a LDCT is typically 10% to 30% of a standard-dose CT.[2] The harms of a screening program would include false-positive results and subsequent unnecessary tests and procedures, the exposure to ionizing radiation and ensuing radiation-induced cancer, and increased anxiety and distress.[2]

Proprietary Information of UnitedHealthcare.
Copyright ©2025 United HealthCare Services, Inc.

- The risk of malignancy associated with a Lung CT Screening Reporting and Data System (Lung-RADS) score is as follows: a score of 2 is <1%; a score of 3 is 1%-2%; a score of 4A is 5%-15%; a score of 4B and 4X is >15%.[3] The American College of Radiology (ACR) recommends follow up imaging of incidental pulmonary nodules detected on low dose lung cancer screening CT's based on the Lung-RADS score;[3,5] however, there is limited data on the impact of screening intervals.[5] The NLST and NELSON studies demonstrating reduction in lung cancer mortality were based on screening intervals of 1 year and 1, 3, and 5.5 years, respectively.[5] Multiple studies have shown that the 3 month follow up recommended for Lung-RADS 4A nodules is optimal, but have raised concerns on stepwise downgrading of a stable 4A nodule to a Lung-RAD 2.[5] Therefore the ACR has modified follow up intervals with stepped management using the following criteria:
  - Nodules that are stable or decreased at follow-up are downgraded to the next lower Lung-RADS category.[5]
  - Nodules that completely resolve or are proven benign after an appropriate diagnostic evaluation are reclassified based on the most concerning finding.[5]
  - Follow-up recommendations are timed from the current examination.[5]

For further specific details concerning Lung-RADS, see v2022 by the ACR.[3]

General Guidelines (HD-1.0)

HD.GG.0001.0.A
v2.0.2026

- A pertinent clinical evaluation including a detailed history, physical examination including a neurological examination since the onset or change in symptoms, and appropriate laboratory studies should be performed prior to considering the use of an advanced imaging (CT, MR, Nuclear Medicine) procedure.
  - A pertinent clinical evaluation furnished via telehealth, since the onset or change in symptoms, is treated the same as an in-person clinical evaluation.
  - An exception to a pertinent clinical evaluation can be made if the individual is undergoing a guideline-supported, scheduled follow-up imaging evaluation.
    - Scheduled follow-up of known problems such as, multiple sclerosis, tumors, or hydrocephalus, scheduled surveillance with no new symptoms, screening asymptomatic individual due to family history or otherwise meet criteria for repeat imaging, as well as appropriate laboratory studies and non-advanced imaging modalities
  - A detailed neurological exam is required prior to advanced imaging except in the following scenarios:
    - Tinnitus, TMJ, sinus or mastoid disease, ear pain, hearing loss, eye disease, pituitary disease, and epistaxis. (A pertinent clinical evaluation since onset of symptoms is still required)
    - The request is from a neurologist, neurosurgeon, neuro-ophthalmologist, endocrinologist, gynecologist, otolaryngologist, or ophthalmologist who has seen the individual since onset of symptoms, or any provider in consultation with one of the above specialists.
- Other meaningful contact (telephone call, electronic mail, or messaging) since the onset or change in symptoms, with an established individual can substitute for a face-to-face clinical evaluation
- CT Head contrast as requested (CPT® 70450 OR CPT® 70460 OR CPT® 70470) is medically necessary when MRI is contraindicated.

Health Equity Consideration

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence;

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

General Guidelines – Anatomic Issues (HD-1.1)

HD.GG.0001.1.A
v2.0.2026

- If two studies using the same modality both cover the anatomic region of clinical interest, only one is generally needed, with the exception of the following scenarios:
  - CT Maxillofacial (CPT® 70486, CPT® 70487, or CPT® 70488) or CT Orbit/Temporal bone (CPT® 70480, CPT® 70481, or CPT® 70482): both cover the structures of the orbits, sinuses, and face. Two separate imaging studies are only supported if there is suspicion of simultaneous involvement of more posterior lesions, especially of the region involving the middle or inner ear.
  - Pituitary Gland: one study (either MRI Brain [CPT® 70553] or MRI Orbit/Face/Neck [CPT® 70543]) is adequate to report the imaging of the pituitary. If a previous routine MRI Brain was reported to show a possible pituitary tumor, a repeat MRI with dedicated pituitary protocol is supported.
  - Internal Auditory Canal: (IAC) MRI can be reported as a limited study with one code from the set (CPT® 70540, CPT® 70542, or CPT® 70543), but should not be used in conjunction with MRI Brain codes (CPT® 70551, CPT® 70552, or CPT® 70553) if IAC views are performed as part of the brain.
  - Mandible (jaw): CT Maxillofacial (CPT® 70486, CPT® 70487, or CPT® 70488) or CT Neck (CPT® 70490, CPT® 70491, or CPT® 70492) can be used to report imaging of the mandible. CT Neck will also image the submandibular space.
    - If MRI is medically necessary, MRI Orbit/Face/Neck (CPT® 70540, CPT® 70542, or CPT® 70543) can be used to report imaging of the mandible and submandibular space.
    - MRI Temporomandibular Joint(s) (TMJ) is reported as CPT® 70336. This code is inherently bilateral and should not be reported twice on the same date of service.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

General Guidelines – Modality (HD-1.2)

HD.GG.0001.2.A
v2.0.2026

- MRI is preferable to CT for most indications. For exceptions, See **General Guidelines – CT Head (HD-1.4)**
- MRI is medically necessary for these indications following an initial CT:
  - MRI Brain without and with contrast (CPT® 70553) to follow-up abnormalities seen on CT Head without contrast (CPT® 70450) when a mass, lesion, or infection is found.
  - MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) to follow-up abnormalities seen on CT Head without contrast (CPT® 70450) when there is suspected Multiple Sclerosis or other demyelinating disease.
  - MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) to follow up on stroke or TIA when initial CT Head was done on emergent basis.
  - MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) for evaluation of new onset seizures.

Evidence Discussion (HD-1.2)

- MRI of the brain is the appropriate initial imaging study for diagnosis, characterization and surveillance of a variety of neurologic conditions, including, but not limited to: neoplastic conditions, evaluation of the brain parenchyma, meninges, ischemia and infarction, neurodegenerative disorders, hydrocephalus, demyelinating conditions, post-traumatic brain injury, inflammatory and autoimmune disorders and infectious disorders.[9]
- MRI Brain has some benefit over CT for determining age of intracranial hemorrhage, early stroke (via Diffusion imaging sequences), and detection of micro hemorrhage.[9,35,36,37]
- MRI is also medically necessary for further characterization of abnormalities detected on other imaging tests such as CT or sonography.[9]
- Limitations to MRI include artifacts due to motion and susceptibility effects, contrast complications, contraindication due to ferromagnetic devices or implants. Additionally, severe claustrophobia may require sedation in order to complete the study.[33]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

General Guidelines – MRI Brain (HD-1.3)

HD.GG.0001.3.A

v2.0.2026

- MRI Brain with contrast (CPT® 70552) should not be ordered except to follow-up on a very recent abnormal or equivocal non-contrast MRI Brain.
- After an MRI Brain without contrast (CPT® 70551), a follow up MRI Brain with contrast (CPT® 70552) may be performed at the discretion of a neurologist, a neurosurgeon, or a neuro-ophthalmologist, or any provider in consultation with a neurologist, neurosurgeon, or neuro-ophthalmologist, and/or at the recommendation of the radiologist.
- Gadolinium is relatively contraindicated in pregnancy, MRI Brain without contrast (CPT® 70551) is supported.
- The AMA CPT manual does not describe nor assign any minimum or maximum number of sequences for any CT or MRI study. Both MRI and CT imaging protocols are often influenced by the individual clinical situation of the individual and additional sequences are not uncommon. There are numerous MRI sequences that are performed to evaluate specific clinical questions, and this technology is constantly undergoing development. Additional sequences, however, are still performed and coded under the routine MRI Brain CPT® 70551, CPT® 70552, or CPT® 70553.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

General Guidelines – CT Head (HD-1.4)

HD.GG.0001.4.A

v2.0.2026

- Scenarios in which MRI is contraindicated (i.e., pacemakers, ICDs, cochlear implants, aneurysm clips, orbital metallic fragments, etc.)
- In urgent cases, CT Head, contrast as requested is medically necessary [CT Head without contrast (CPT® 70450) or CT Head with contrast (CPT® 70460) or CT Head without and with contrast (CPT® 70470)]
- CT Head without contrast (CPT® 70450) is medically necessary for:
  - Mass effect
  - Blood/blood products
  - Urgent/emergent settings due to availability and speed of CT
  - Trauma
  - Recent hemorrhage, whether traumatic or spontaneous
  - Bony structures of the head evaluations including dystrophic calcifications
  - Hydrocephalus evaluation and follow-up (some centers use limited non-contrast "fast or rapid MRI" (CPT® 70551) to minimize radiation exposure in children).
  - Prior to lumbar puncture in individuals
  - Evaluation of optic disc edema and/or papilledema, a non-contrast CT Head is useful to assess for space-occupying processes such as intracranial hemorrhage, mass effect, and hydrocephalus, See **Papilledema/Pseudotumor Cerebri (HD-17.1)** and **Eye Disorders and Visual Loss (HD-32.1)**

Evidence Discussion (HD-1.4)

- CT head is the preferred modality for evaluation of bony structures, acute intracranial hemorrhage, trauma, and detection of abnormalities associated with calcifications.[35,37,38,39]
- This modality is also useful for follow up of intracranial hemorrhage, hydrocephalus shunts, and post-operative follow-up.[35,37,38,39]
- CT head provides more rapid detection of intracranial abnormalities in urgent or emergent situations.[38,39,40]
- CT has less motion artifact than MRI due to its faster acquisition and better spatial resolution than MRI.
- Limitations of CT include lower early detection rates for occult fracture than MRI, ionizing radiation exposure, and lower contrast resolution than MRI.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

General Guidelines – CT and MR Angiography (CTA/CTV and MRA/MRV) (HD-1.5)

HD.GG.0001.5.A
v2.0.2026

Angiography imaging refers to both arterial and venous imaging. Vascular angiography is not the same imaging as diagnostic MRI.

- MRA Head is performed without contrast (CPT® 70544), with contrast (CPT® 70545), or without and with contrast (CPT® 70546)
- MRA Neck is performed without contrast (CPT® 70547), with contrast (CPT® 70548), or without and with contrast (CPT® 70549), depending on facility preference and protocols and type of scanner
- CTA Head is performed without and with contrast (CPT® 70496)
- CTA Neck is performed without and with contrast (CPT® 70498)
- CTA Head and Neck is performed without and with contrast (CPT® 70471). This code must be substituted when both CTA head and neck are performed together during the same session.
- CT and MR Venography (CTV and MRV) are reported with the same codes as the CTA/MRA counterpart (there is no specific code for CT/MR venography).
  - If arterial and venous CT or MR studies are both performed in the same session, only **one** CPT® code is used to report both procedures.
  - If an arterial CTA or MRA study has been performed and subsequently a repeat study is needed to evaluate the venous anatomy, then this study is medically necessary.
  - If a venous CTV or MRV study has been performed and subsequently a repeat study is needed to evaluate the arterial anatomy, then this study is medically necessary.
- Medically necessary indications for CTA or MRA Head and Neck vessels include, but are not limited to the following:
  - Pulsatile tinnitus
  - Hemifacial spasm if consideration for surgical decompression
  - Evaluation of stroke or TIA (see **Stroke/TIA (HD-21.1)**) including collateral assessment
  - Trigeminal neuralgia (see **Trigeminal Neuralgia and other Centrally Mediated Facial Pain Syndromes (HD-10.1)**)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Cerebral venous sinus thrombosis (see **Cerebral Venous Sinus Thrombosis (HD-21.8)** and **Papilledema/Pseudotumor Cerebri (HD-17.1)**)
    - MRA without and with contrast is medically necessary for venous sinus thrombosis to differentiate total from subtotal occlusion.
  - Aneurysm suspected with acute “thunderclap” headache syndrome and appropriate screening or evaluation of known subarachnoid hemorrhage and pseudoaneurysms (appropriate to limit CTA to include only the head to avoid unnecessary radiation to the individual)
  - Non-inflammatory vasculopathy, including radiation vasculopathy
  - Traumatic vascular injuries
  - Vascular malformations, vascular anatomic variants, and fistulas
  - Arterial dissections
  - Tumors of vascular origin or involving vascular structures
  - Surgical and radiation therapy localization, planning, and neuronavigation
  - Evaluation for vascular intervention and follow-up including post-surgical/post-treatment vascular complications
  - Intra-cranial pre-operative planning if there is concern of possible vascular involvement or risk for vascular complication from procedure
  - Vasculitis and collagen vascular disease
  - Eagle Syndrome - Dynamic/positional CTA to assess for vascular compression (also known as bow-hunter's syndrome) (see **Eagle Syndrome (Neck-10.3)**)
  - NOTE: Evaluation of posterior circulation disease requires both neck and head MRA/CTA to visualize the entire vertebral-basilar system.
- MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) or CTA Head (CPT® 70496) is medically necessary for follow-up of aneurysm clipping or coiling procedures (see **Intracranial Cerebral Aneurysms (HD-12.1)**)
- MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) or CTA Head (CPT® 70496) **AND/OR** MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) or CTA Neck (CPT® 70498) is medically necessary if arterial dissection is suspected, or known and re-evaluation is needed (as directed by neurologist or neurosurgeon or any provider in consultation with a neurologist or neurosurgeon)
  - There are high-risk scenarios including, but not exclusive to, fibromuscular dysplasia (FMD), Marfan disease, motor vehicle accident (MVA) with whiplash, or chiropractic manipulation.
- Other vascular imaging indications for headaches require additional information.
  - See **Stroke/TIA (HD-21.1)**, **Sudden Onset of Headache (HD-11.3)**, **New Headache Onset Older than Age 50 (HD-11.7)**, **Abnormal Blood Clotting (HD-11.9)**, **Pregnancy (HD-11.10)**, **Physical Exertion (HD-11.11)**, and **Systemic Infections (HD-11.13)**

Evidence Discussion (HD-1.5)

- Indications for cervicocerebral computed tomography angiography (CTA) of the head and neck vessels include the diagnosis, characterization and/or surveillance of a variety of vascular conditions, including, but not limited to, arterial aneurysms, dissections, ischemic stroke and transient ischemic attacks, vasculitis, traumatic vascular injuries, pulsatile tinnitus, tumors of vascular origin, and prior to surgical intervention.[8] CTA may refer to arterial vessels (CTA) or evaluation of venous structures (CTV).[8]
- CTA may be used as the initial imaging modality or as a follow up study for characterizing known disease or assessing changes over time.[8]
- Depending on the indication, CTA may be limited to the head to avoid unnecessary radiation to the individual. Examples include surveillance of intracranial aneurysms (that are not located in the posterior circulation).[8]
- Risks of CTA include exposure to ionizing radiation; thus, magnetic resonance angiography (MRA) is available as an alternative to reduce radiation exposure. In addition, MRA is an alternative for individuals with iodinated contrast allergies or other contraindications to iodinated contrast.[8,41]
- Magnetic resonance angiography (MRA) indications also cover a variety of vascular conditions of the head and neck, for diagnosis, characterization, and surveillance, and may be used to evaluate either arterial (MRA) or venous structures (MRV).[41]
- MRA, as an alternative modality, is noninvasive, and does not require iodinated contrast.[41] Limitations include artifacts due to motion, slow or turbulent flow, and susceptibility effects, and claustrophobia.[41] MRA may be performed without contrast or with gadolinium contrast.[41] Gadolinium contrast administration is limited to those without renal impairment or known gadolinium contrast allergy.[41] Additionally, MRA may not be a feasible option for those with contraindications to MRI such as incompatible pacemakers, cochlear implants, neurostimulators, or other devices.[33] In these scenarios, CTA may be the appropriate alternative.[8]

General Guidelines – Other Imaging Situations (HD-1.7)

HD.GG.0001.7.A
v2.0.2026

Persistent Nausea and Vomiting

Screening for Metallic Fragments Before MRI

Gender Affirming Care Head and Neck Surgical Planning

3D Rendering

Eagle Syndrome

CSF Leak with or without Headache

Evidence Discussion (HD-1.7)

Persistent Nausea and Vomiting

- Nausea and vomiting, persistent, unexplained and a negative GI evaluation: MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) is medically necessary

Screening for Metallic Fragments Before MRI

- Screening for metallic fragments before MRI should be done initially with plain x- ray.
  - The use of CT Orbital to rule out orbital metallic fragments prior to MRI is rarely necessary.
  - Plain x-rays are generally sufficient; x-ray detects fragments of 0.12 mm or more, and CT detects those of 0.07 mm or more.
- Plain x-ray is generally sufficient to screen for aneurysm clips

Gender Affirming Care Head and Neck Surgical Planning

- For gender affirming care procedure planning:
  - ANY or ALL the following pre-operative CT requests are medically necessary if the individual has a health plan benefit covering the gender affirming surgeries:
    - CT Maxillofacial without contrast (CPT® 70486)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

        - CT Orbits/Temporal bone without contrast (CPT® 70480)
        - CT Neck with contrast (CPT® 70491)
        - CT Head without (CPT® 70450)
        - 3D rendering (CPT® 76376 or CPT® 76377)
    - Pre-operative imaging is not supported if the gender affirming surgeries are not health plan covered benefits.
    - Requesting providers are encouraged to confirm eligibility with the member's health plan prior to service.

3D Rendering

- CPT® 76376 (3D rendering not requiring imaging post-processing on an independent workstation) or CPT® 76377 (3D rendering requiring image post-processing on an independent workstation) is medically necessary in the following clinical scenarios:
    - Bony conditions:
        - Evaluation of congenital skull abnormalities in newborns, infants, and toddler (usually for pre-operative planning)
        - Complex joint fractures or pelvis fractures
        - Spine fractures (usually for pre-operative planning)
        - Complex facial fractures
    - Pre-operative planning for other complex surgical cases
    - Cerebral angiography: 3D rendering when performed in conjunction with conventional angiography (i.e., conventional 4 vessel cerebral angiography).
        - See **Cerebral Aneurysms (HD-12.1)**, **Arteriovenous Malformations (AVMs) and Related Lesions (HD-12.2)**, **Stroke/TIA (HD-21.1)**, and **Cerebral Vasculitis (HD-22.1)**[26]
- 3D Rendering (CPT® 76376 or CPT® 76377) for surgical planning and surgical follow up after craniotomy when ordered by surgical specialist or any provider in consultation with a surgical specialist.
- 3D Rendering indications in pediatric head imaging are identical to those in the general imaging guidelines.
- See **3D Rendering (Preface-4.1)** in the Preface Imaging Guidelines

Eagle Syndrome

- See **Eagle Syndrome (Neck-10.3)** in the Neck Imaging Guidelines.
- See **General Guidelines - CT and MR Angiography (CTA/CTV and MRA/MRV) (HD-1.5)** for vascular imaging related to Eagle Syndrome.

Proprietary Information of UnitedHealthcare.

CSF Leak with or without Headache

- CSF Leak with or without headache, see **Low-Pressure Headache and CSF Leak (HD-11.15)**

Evidence Discussion (HD-1.7)

Neurologic evaluation of Nausea and vomiting

- In the evaluation of persistent, unexplained nausea and vomiting, an MRI Brain is supported after a negative GI evaluation.[2,3,4,43] Nausea and vomiting were reported as the initial symptom of a brain tumor in 5% of brain tumor cases.[44] During the time course until diagnosis, nausea and vomiting is present in 25% of brain tumor cases.[44]

Screening for metallic fragments

- The American College of Radiology White Paper on MR safety advised that all individuals who have a history of orbit trauma by a potential ferromagnetic foreign body for which they sought medical attention are to have their orbits cleared by either a plain x-ray orbit films (2 views) or by a radiologist's review and assessment of a prior CT or MR images obtained since the suspected traumatic event.[42,46] Screening for the presence of a metallic aneurysm clips with plain films of the skull is also recommended.[46] Although CT is more sensitive than plain films, the radiation dose is greatly increased.[42]

3D Rendering

- 3-D/rotational angiography, as part of cerebral angiography, is also useful for radiation dose reduction during diagnostic and interventional neuroradiology procedures.[22]

Gender affirming head and neck surgeries

- As the field has evolved, more centers are using frontal sinus setback as 90% of individuals require frontal bone osteotomy and setback, based on their frontal bone anatomy.[31,32] For individuals requiring bony manipulation, a fine-cut, non-contrast craniofacial CT scan from the vertex to the hyoid bone is used to map the bony framework.[31,32] Virtual surgical planning improves efficiency, safety, and accuracy for frontal sinus setback and mandibular angle reduction surgeries.[45] CT Neck is medically necessary for laryngoplasty surgeries.[6]

Taste and Smell Disorders (HD-2.1)

HD.TS.0002.1.A
v2.0.2026

- MRI Brain without and with contrast (CPT® 70553) or MRI Brain without and with contrast (CPT® 70551) **AND/OR** MRI Orbit/Face/Neck without (CPT® 70540) or MRI Orbit/Face/Neck without and with contrast (CPT® 70543) is medically necessary with unexplained unilateral or bilateral anosmia (inability to perceive odor) or dysgeusia (complete or partial loss of taste)
- CT Maxillofacial (CPT® 70486, CPT® 70487 or CPT® 70488) is medically necessary initially if sinus or facial bone disorders are suspected
- For individuals who test positive for SARS-CoV-2 (see: **Neuro-COVID-19 and Sars-CoV-2 Vaccines (HD-14.2)** and **Stroke/TIA (HD-21.1)**)

Evidence Discussion (HD-2.1)

- Initial imaging of the olfactory nerve and pathway for unexplained unilateral or bilateral anosmia or for dysgeusia should utilize MRI brain and/or MRI orbits, face and neck.[1,6] These imaging studies are supported by clinical evidence for the identification and characterization of a potential cranial nerve lesion.[1,6]
- CT of the sinuses and face may be superior to identify fractures, inflammatory sinus disease, and other bony lesions in some cases.[1]

Ataxia (HD-3.1)

HD.AX.0003.1.A
v2.0.2026

- Common manifestations include poor coordination, an abnormal (including wide-based) gait, abnormal finger to nose testing, abnormal rapid alternating movements, abnormal eye movements, and/or difficulty with navigation of stairs and around corners.
- MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) is medically necessary in all individuals with ataxia:
  - MRI Cervical without contrast or without and with contrast (CPT® 72141 or CPT® 72156) **AND/OR** MRI Thoracic without contrast or without and with contrast (CPT® 72146 or CPT® 72157) **AND/OR** MRI Lumbar Spine without contrast or without and with contrast (CPT® 72148 or CPT® 72158) may be added if spinal disease is suspected
  - If these symptoms are acute and stroke is suspected, see **Stroke/TIA (HD-21.1)**
  - If MS is suspected, see **Multiple Sclerosis (MS) (HD-16.1)**
  - CT Head without contrast (CPT® 70450) **AND/OR** CT Orbit/Temporal Bone without contrast (CPT® 70480) is medically necessary in addition if these symptoms are acute following head trauma, (see also: **Head Trauma (HD-13.1)**)
- If brain tumor is suspected, see **Primary Central Nervous System Tumors (ONC-2.1)** in the Oncology Imaging Guidelines.
- For suspected Normal Pressure Hydrocephalus, see **Normal Pressure Hydrocephalus (NPH) (HD-8.4)**

Background and Supporting Information

- In general, MRI is preferred over CT, unless there is a history of acute trauma or contraindication to MRI. For all other causes, MRI provides better visualization of the cerebellum and posterior fossa.

Evidence Discussion (HD-3.1)

- MRI Brain is the preferred initial imaging modality for evaluation of ataxia when a central nervous system cause is suspected.[1,4] MRI of the spinal cord, to include the cervical and thoracic spine, may also be added if clinically indicated.[1,5]
- CT head is not recommended for the initial evaluation of non-traumatic ataxia due to inferior soft tissue resolution when compared to MRI Brain. In addition, MRI Brain provides better visualization of the cerebellum and posterior fossa and is more sensitive for the detection of posterior fossa infarcts.[1]

Autism Spectrum Disorders (HD-4.0)

HD.BD.0004.0.A

v2.0.2026

- This group of diagnoses, including Asperger syndrome, is classified as pervasive development disorders (PDD). These diagnoses are established on clinical criteria, and no imaging study can confirm the diagnosis.
- Comprehensive evaluation for autism might include history, physical exam, audiology evaluation, speech, language, and communication assessment, cognitive and behavioral assessments, and academic assessment.
  - MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551) is medically necessary for **ANY** of the following:
    - New or worsening cognitive decline or focal neurologic findings documented on a pertinent physical
  - PET imaging is considered not medically necessary in the evaluation of individuals with autism spectrum disorders.

Evidence Discussion (HD-4.0)

- While the diagnosis of Autism Spectrum Disorder is based on behavioral signs and symptoms, MRI Brain without and with contrast is medically necessary for new or worsening focal neurological findings and/or loss of developmental milestones and/or regression. In these clinical situations, advanced imaging may be used to adjust an individual's treatment plan, without which their development may continue to regress.[4]
- PET is considered not currently medically necessary in the evaluation of individuals with autism spectrum disorder PET imaging in this scenario would unnecessarily expose individuals to radiation and provide no clinical utility related to autism spectrum disorder.[5]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Mental Health Related Disorders (HD-4.1)

HD.BD.0004.1.A
v2.0.2026

- Mental health diagnoses, to include Attention Deficit Hyperactivity Disorder (ADHD), do not routinely require advanced imaging.
- MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) **OR** CT Head without contrast (CPT® 70450) is medically necessary for the exceptions listed below:
  - Acute mental status change, disturbance in consciousness or arousal state
  - Psychotic disorders (including schizophrenia), bipolar disorder and related disorders in the following clinical presentations:
    - Acute psychosis
    - Late onset over age 40
    - Presentation of acute psychiatric symptoms with comorbid serious medical illness
    - Non-auditory hallucinations (e.g., visual, tactile, olfactory) with no known etiology
    - Nonresponse to adequate medication trials
    - Symptoms of an organic brain disorder (e.g., focal deficits, severe headache, or seizures)
- Prior to electroconvulsive therapy (ECT) treatment, the following are medically necessary to screen for intracranial disease: MRI Brain without contrast (CPT® 70551) **OR** CT Head without contrast (CPT® 70450)
- Deep Brain Stimulation Therapy for psychiatric disorders is considered not medically necessary, except for medically refractory Obsessive Compulsive Disorder (OCD).
  - Medically necessary imaging prior to Deep Brain Stimulation (DBS) therapy for medically refractory Obsessive Compulsive Disorder (OCD):
    - MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) **AND/OR** unlisted CT procedure code (CPT® 76497)

Evidence Discussion (HD-4.1)

- There is no role for advanced imaging in mental health workup (including ADHD). Unnecessary imaging has detrimental effects in that it provides no positive impact on outcomes/management and does expose individuals to unnecessary radiation, contrast, and financial strain.
- It would be appropriate to utilize Advanced imaging (CT or MRI) in the following conditions.
  - Acute mental status change, disturbance in consciousness or arousal state[2]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Psychiatric disorders with the following clinical presentations[2]:
  - Acute psychosis
  - Late onset over age 40
  - Presentation of acute psychiatric symptoms with comorbid serious medical illness
  - Non-auditory hallucinations of unknown etiology
  - Nonresponse to adequate medication trials
  - Symptoms of an organic brain disorder (e.g., focal deficits, severe headache, or seizures)

- Advanced imaging may be medically necessary for electroconvulsive therapy clearance and prior to deep brain stimulation for medically refractory obsessive compulsive disorder.[10]

Mental Status Change (HD-4.2)

HD.BD.0004.2.A
v2.0.2026

After a detailed history, which includes onset, duration, and timeframe (i.e., constant vs intermittent) **AND** bedside neurologic exam that includes a mental status evaluation providing a description of the level of alertness, other characteristics and/or cognitive testing, the following are medically necessary:

Indication	Medically Necessary Imaging
Acute or worsening mental status change, initial or repeat imaging	• CT Head without contrast (CPT® 70450) **OR** • If setting is urgent, CT Head contrast as requested (CPT® 70450 OR CPT® 70460 OR CPT® 70470) **OR** • If MRI is contraindicated, CT Head contrast as requested (CPT® 70450 OR CPT® 70460 OR CPT® 70470) • *CT Head permitted even with prior MRI Brain imaging* **OR** • MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553) • *MRI Brain permitted even with prior head CT imaging*

Indication	Medically Necessary Imaging
*Presence of any Red Flag, including: • Sudden language, focal motor, or sensory deficit – **Stroke/TIA (HD-21.1)** • Headache – **Headaches with Red Flags (HD-11.2)** • Hypertensive urgency – **Stroke/TIA (HD-21.1)** and **Sudden Onset of Headache (HD-11.3)** • Fever/tachycardia, possible meningitis, or other CNS infection – **CNS and Head Infection (HD-14.1)** • COVID-19 – **Neuro-COVID-19 and Sars-CoV-2 Vaccines (HD-14.2)** • Coagulopathy or anticoagulant use- **Abnormal Blood Clotting (HD-11.9)** • Pregnancy or post-partum – **Pregnancy (HD-11.10)** • Known malignancy – **Low Grade Gliomas (ONC-2.2)**, **High Grade Gliomas (ONC-2.3)** and **Brain Metastases (ONC-31.3)** • Trauma- **Head Trauma (HD-13.1)** • Non-auditory hallucinations – **Mental Health Related Disorders (HD-4.1)** • Suspected increased intracranial pressure – **Papilledema/Pseudotumor Cerebri (HD-17.1)** and **Hydrocephalus Shunts (HD-11.14)** • Seizure/suspected seizure – **Epilepsy/ Seizures (HD-9.1)**	*See relevant guideline

Background and Supporting Information

This section refers to acute/subacute mental status change, which generally involves signs and symptoms which begin over minutes to days, and includes changes in behavior and alertness, agitation, and/or confusion – as opposed to chronic, progressive cognitive decline, as in dementia.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Acute mental status change or encephalopathy is characterized by changes in behavior or alertness, agitation, confusion, as opposed to chronic, progressive cognitive decline, such as dementia related disorders.

Delirium and psychosis are defined as follows:

- Delirium is a disorder of acute onset involving deficits in attention, awareness, and cognition that fluctuate in severity over time. These are often associated with psychomotor disturbance, altered sleep cycle, and emotional variability. These disturbances may be hyperactive (restlessness, agitation) or hypoactive (psychomotor retardation, lethargy) and there may be accompanying fever and/or autonomic symptoms (tachycardia, sweating), depending on the underlying cause.
- Psychosis is a disorder of impaired reality, characterized by hallucinations, delusions, or both, without insight into their pathologic nature. It may be associated with disorganized behavior, thought blocking, illogicality, tangentiality, perseveration, and/or neologisms.

The purpose of the initial assessment is to characterize the etiology. This may include toxic/metabolic (e.g., hypoglycemic, drug exposures), structural (e.g., trauma, stroke, hypoxic-ischemic, hydrocephalus, tumor), paroxysmal (e.g., seizure, psychiatric), and inflammatory (e.g., infectious, autoimmune).

Of note, even a seemingly mild, reversible brain insult superimposed upon a chronic pathophysiologic process may cause a sudden mental status change, and head imaging may or may not be necessary, depending on the provider's pre-test suspicion of a significant new diagnosis.

Vagal Nerve Stimulators (VNS), which are FDA approved for treatment of depression, are included among potential treatments, which also include medication trials.

Evidence Discussion (HD-4.2)

- Advanced brain imaging is supported for acute onset of mental status change, or worsening symptoms in the setting of a known intracranial process with MRI Brain with or without a previous CT Head.[1]
- Advanced imaging supported for mental status change with precipitating factors including suspected seizure, COVID related symptoms, head trauma, stroke, mass, or known malignancy, suspected increased intracranial pressure, intracranial infection, hypertensive emergency, presence of coagulopathy, pregnancy and postpartum period, associated headache.[2]
- According to the ACR, advantages of MRI for altered mental state include: 1) higher sensitivity for detection of ischemia, encephalitis, subtle cases of SAH; and 2) enhancement of pathology compared with CT. The disadvantages of MRI in this clinical scenario are the same as with MRI in general, including individual

Proprietary Information of UnitedHealthcare.

Chiari Malformations (HD-5.1)

HD.CM.0005.1.A
v2.0.2026

Indication	Medically Necessary Imaging
Initial evaluation for suspected or known Chiari malformations	• MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) **AND/OR** • MRI Cervical Spine without contrast (CPT® 72141) or MRI Cervical Spine without and with contrast (CPT® 72156) **AND/OR** • MRI Thoracic Spine without contrast (CPT® 72146) or MRI Thoracic Spine without and with contrast (CPT® 72157) **AND/OR** • MRI Lumbar Spine without contrast (CPT® 72148) or MRI Lumbar Spine without and with contrast (CPT® 72158)
Repeat imaging for one of the following: • New or worsening signs or symptoms • Surgical procedure is actively being considered • At the discretion of or in consultation with a neurologist and/or neurosurgeon coordinating the individual's care	• MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) **AND/OR** • MRI Cervical Spine without contrast (CPT® 72141) or MRI Cervical Spine without and with contrast (CPT® 72156) **AND/OR** • MRI Thoracic Spine without contrast (CPT® 72146) or MRI Thoracic Spine without and with contrast (CPT® 72157) **AND/OR** • MRI Lumbar Spine without contrast (CPT® 72148) or MRI Lumbar Spine without and with contrast (CPT® 72158)

- Familial screening is NOT medically necessary for Chiari Malformations.
- For CSF flow imaging, see **CSF Flow Imaging (HD-24.4)**

Background and Supporting Information

Chiari I malformations involve caudal displacement or herniation of the cerebellar tonsils. Chiari I may be associated with syringomyelia and rarely with hydrocephalus. Most cases are asymptomatic and discovered incidentally on a head scan performed for another indication. When symptoms are present, they are usually nonspecific but can include headache, lower cranial nerve palsies, or sleep apnea.

Chiari II malformations are more severe than Chiari I malformations. These individuals usually present at birth. Myelomeningocele is always present, and syringomyelia and hydrocephalus are extremely common.

Chiari III malformations include cerebellar herniation into a high cervical myelomeningocele. Chiari IV malformation refers to complete cerebellar agenesis. Both Chiari III and IV malformations are noted at birth and are rarely compatible with life.

Repeat brain and spine imaging in individuals with Chiari I malformations and known syringomyelia or hydromyelia is highly individualized.

Basilar Impression/Basilar Invagination (HD-5.4)

HD.CM.0005.4.A
v2.0.2026

Medically necessary imaging for suspected or known Basilar Impression or Basilar Invagination:

- MRI Brain without contrast (CPT® 70551) **AND/OR** MRI Cervical Spine without contrast (CPT® 72141)
- If surgery is being considered, CT Head (CPT® 70450) **AND/OR** CT Cervical Spine (CPT® 72125) without contrast are also medically necessary **AND/OR** MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **OR** CTA Head (CPT® 70496) **AND/OR** MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) **OR** CTA Neck (CPT® 70498)
  - CTA Head and Neck (CPT® 70471) must be substituted for CTA Head (CPT® 70496) and CTA Neck (CPT® 70498) when performed during the same session.
- One-time screening of first-degree relatives with MRI Brain without contrast (CPT® 70551) is medically necessary.

Background and Supporting Information

Basilar impression involves malformation of the occipital bone in relation to C1-2 (cervical vertebrae 1 and 2). The top of the spinal cord is inside the posterior fossa and the foramen magnum is undersized. Over time, this can lead to brain stem and upper spinal cord compression. Basilar impression can also be associated with the Chiari malformation, producing very complex anatomical abnormalities.

Basilar invagination is an abnormality at the craniovertebral junction, either congenital or degenerative, resulting in the odontoid prolapsing into the already limited space of the foramen magnum. It is commonly associated with conditions such as Chiari malformation, syringomyelia, and Klippel-Feil syndrome.[12]

Click Here to Return to the Main TOC

Platybasia (HD-5.5)

HD.CM.0005.5.A
v2.0.2026

Medically necessary imaging indications for suspected or known Platybasia:

- MRI Brain without contrast (CPT®70551) or CT Head without contrast (CPT®70450)
- If surgery is being considered,
  - CT Head (CPT®70450) **AND/OR**
  - CT Cervical Spine (CPT®72125) **AND/OR**
  - MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **OR**
  - CTA Head (CPT® 70496) **AND/OR**
  - MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) **OR**
  - CTA Neck (CPT® 70498)
    - CTA Head and Neck (CPT® 70471) must be substituted when CTA Head (CPT® 70496) and CTA Neck (CPT® 70498) are performed during the same session.

Background and Supporting Information

Platybasia is a flattening malformation of the skull base, in which the clivus has a horizontal orientation.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Evidence Discussion (HD-5)

v2.0.2026

- A CT scan of the head is less sensitive than an MRI of the brain for evaluation of intracranial structures, including major structural abnormalities of the posterior fossa.[14,15]
- Neuroimaging in the initial evaluation of Chiari malformation should include the spinal cord due to the common occurrence or increased frequency of associated conditions such as cervical syrinx and tethered cord.[1,2,3,4,9,10]
- For initial evaluation, treatment planning, and follow up, MRI is the preferred modality for malformations of the brain and cervicocranial junction.[7,14,15,16] MRI is ideal for evaluating soft tissues, neural structures, and ligaments.[7,13]
- As congenital brainstem and cerebellar anomalies are associated with spinal anomalies, MRI of the complete spine is helpful for diagnosis, follow up, and treatment planning.[1,2,3,4,14]
- A phase-contrast CSF flow study at the craniocervical junction is a supportive study for evaluation of Chiari malformation.[5,16]
- Evaluation of cervicojunction anomalies, including basilar invagination and platybasia, may require more than one modality for diagnosis and surgical planning.[7,12,13] CT characterizes osseous anatomy and may be helpful for surgical planning.[7,13] MRI is preferred for evaluation of the soft tissues, neural structures, and ligaments for these conditions.[7,13] As craniocervical junction anomalies may lead to compression of adjacent vascular structures, CT- or MR-Angiography of the head and neck are useful for surgical planning.[13]

Facial Palsy (HD-6.1)

HD.FP.0006.1.A
v2.0.2026

- MRI Brain without contrast (CPT® 70551) (with attention to posterior fossa and IACs) or MRI Brain without and with contrast (CPT® 70553) (with attention to posterior fossa and IACs) **AND/OR** MRI Orbit/Face/Neck without contrast (CPT® 70540) or MRI Orbit/Face/Neck without and with contrast (CPT® 70543) is/are medically necessary when unexplained facial paresis/paralysis is associated with any of the following "red flag" clinical scenarios:
  - Trauma to the temporal bone
  - History of tumor, cancer, HIV, or Lyme disease
  - No improvement in 8 weeks
  - No full recovery in 3 months
  - Gradual onset over weeks to months
  - Vertigo or hearing loss
  - Bilateral involvement
  - Other atypical or inconsistent features including:
    - Second episode of paralysis on the same side
    - Paralysis of isolated branches of the facial nerve
    - Paralysis associated with other cranial nerves
- MRI Brain without and with contrast (CPT® 70553) is medically necessary for known sarcoidosis with suspected neurosarcoid or CNS involvement is supported, (see also **Autoimmune/ Paraneoplastic Encephalitis & NeuroInflammatory Disorders (HD-14.3)**)
- CT Orbit/Temporal Bone without contrast (CPT® 70480) is medically necessary, in the presence of "red flags", to assess osseous integrity of the temporal bone, to characterize fractures, pre-surgical anatomy, inflammatory middle ear disease, bone tumor, facial canal foraminal expansion and/or bone erosion.
- CT Orbit/Temporal Bone with contrast (CPT® 70481) is medically necessary, in the presence of red flags, for suspected tumors and/or infection.
- CT Maxillofacial without contrast (CPT® 70486) is medically necessary to assess bony facial nerve canal **OR** with contrast (CPT® 70487) when infection or tumor are suspected, if requested per institutional protocol.
- MRA Head without contrast (CPT® 70544), with contrast (CPT® 70545), or without and with contrast (CPT® 70546) **AND/OR** MRA Neck without contrast (CPT® 70547), with contrast (CPT® 70548), or without and with contrast (CPT® 70549) **OR** CTA Head (CPT® 70496) **AND/OR** CTA Neck (CPT® 70498) **OR** CTA Head and Neck (CPT® 70471) (combination code must be used when both CTA Head (CPT® 70496) and CTA Neck (CPT® 70498) are performed during the same session), is/are

medically necessary for clinically suspected stroke (see **General Guidelines- CT and MR Angiography (CTA/CTV and MRA/MRV) (HD-1.5)** and **Stroke/TIA (HD-21.1)**).

Background and Supporting Information

Typical features of Bell's palsy include variable initial ipsilateral temporal and auricular pain before facial weakness, onset over 72 hours, ipsilateral complete facial weakness, and an otherwise normal neurological and systemic examination. There is usually slow improvement over several months. Unless "red flags" are present, imaging is not medically necessary.

Hemifacial Spasm (HD-6.2)

HD.FP.0006.2.A
v2.0.2026

- For hemifacial spasm, facial synkinesis, or blepharospasm, the following are medically necessary:
  - MRI Brain without and with contrast (CPT® 70553)
  - Add CTA Head (CPT® 70496) or MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) for consideration of vascular decompression surgical procedure to clarify the vascular anatomy in individuals who have failed conservative medical management
- For tardive dyskinesia, see **Movement Disorders (HD-15.1)**

Evidence Discussion (HD-6)

v2.0.2026

- Facial nerve palsy/Bell's Palsy, commonly referred to as Bell's Palsy, does not routinely require imaging as recommended by the American Academy of Neurology and the American Academy of Otolaryngology Head and Neck Surgery Foundation.[1,2,3,4,6] Complete recovery typically occurs within 3 to 6 months.[12]
- When imaging is medically necessary, MRI is the preferred modality for evaluating the facial nerve from its origin in the brainstem, through its intracranial and extracranial segments.[2] This would include imaging of the brain, face or both areas concurrently.[2] MRI is useful to exclude structural causes of facial nerve paralysis in the setting of red flags.[2]
- Imaging is reserved for cases with "red flags," which include atypical, recurrent, or persistent cases.[2,4,10,12] Limiting imaging to those with "red flags" avoids unnecessary radiation exposure, identification of incidental findings, contrast reactions, and unnecessary costs.[1,7] The risk of limiting imaging includes missing identifiable and treatable causes of facial paralysis. To mitigate this risk, clinical follow up is recommended at 3 months.[1]
- MRI has sensitivity ranging from 73% to 100% in detecting peripheral spread of tumor.[2]
- As the facial nerve courses through the temporal bone, CT temporal bone is useful to identify temporal bone fractures, bony anatomy, bone erosion and for surgical planning.[2]
- Vascular imaging is helpful if stroke is clinically suspected.[2]
- For evaluation of hemifacial spasm, MRA allows characterization of vascular loops compressing the facial nerve, with sensitivity >95% and correlates well with surgical findings.[2,3]

Mild Cognitive Impairment (MCI) Evaluation

Dementia Evaluation

Imaging Related to Alzheimer's Treatment with Amyloid Reduction Medications

Background and Supporting Information

Evidence Discussion (HD-8.1)

- For subjective cognitive decline with normal cognitive testing, advanced imaging is not medically necessary.

Mild Cognitive Impairment (MCI) Evaluation

For the evaluation of memory loss and/or cognitive impairment due to suspected Mild Cognitive Impairment (MCI) when treatment with amyloid reducing medications is not documented.

- MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) or CT Head without contrast (CPT® 70450) is medically necessary when **ALL** the following criteria are met:
  - a detailed history of cognitive decline with impairments confirmed by family members or others with knowledge of the individual's status

    OR
  - abnormal mental status test score or neuropsychological test results consistent with mild cognitive impairment/mild neurocognitive disorder
    - Examples of abnormal mental status test results consistent with MCI include neuropsychological testing demonstrating a decline in cognitive function and/or the following test scores:
      - Montreal Cognitive Assessment (MOCA) not < 17,
      - Saint Louis University Mental Status (SLUMS) not < 20, or
      - Mini Mental State Exam (MMSE) not < 20
  - See *Background and Supporting Information* for additional information regarding the diagnosis of MCI

Dementia Evaluation

For the evaluation of memory loss and/or cognitive impairment due to suspected dementia when treatment with amyloid reducing medications is not documented.

- MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) or CT Head without contrast (CPT® 70450) is medically necessary when all the following criteria are met:
  - initial clinical diagnosis of dementia has been established
  - a detailed history and neurologic exam including mental status testing should be performed prior to advanced imaging
  - date of onset of symptoms with documentation of six (6) months of cognitive decline
  - documentation of a decline in cognitive function obtained with **either**:
    - a detailed history of memory loss with impairment of day-to-day activities confirmed by family members or others with knowledge of the individual's status

      OR
    - abnormal mental status test score consistent with dementia or neuropsychological test results consistent with dementia/major neurocognitive disorder
      - examples of abnormal bedside mental status testing scores include:
        - Mini-Mental State Exam (MMSE) <26,
        - Montreal Cognitive Assessment (MoCA) <26,
        - Memory Impairment Screen (MIS) <5,
        - St. Louis University Mental Status (SLUMS) <21, or
        - Eight-item Informant Interview to Differentiate Aging and Dementia (AD8) Dementia Score >2
  - Presumptive causes of dementia have been excluded
    - cannot occur exclusively during bouts of delirium
    - cannot be explained by another mental disorder

- For evaluation of suspected vascular dementia see **Cerebrovascular Disease (HD-21.1)**

Background and Supporting Information

Subjective cognitive decline (SCD) refers to individuals who are concerned about a cognitive decline but perform normally on cognitive testing.

Mild Cognitive Impairment (MCI), also referred to as mild neurocognitive disorder, is marked by focal or multifocal cognitive impairment with minimal impairment of instrumental activities of daily living that do not cross the threshold for dementia.

Cognitive domains affected by MCI may include memory, attention, language, visuospatial processing, executive function, and social behavior. Examples of memory loss include forgetfulness, repeating questions, forgetting recent events or conversations. Attention deficits may include periods of decreased alertness or distractibility. Language impairment may be displayed as word finding difficulties, difficulty communicating and/or understanding. Visuospatial processing impairment may present as getting lost. Executive dysfunction including difficulty completing multi-step commands, planning, or using appliances. Concerning social behaviors include impulsiveness and inappropriate behaviors.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

The functional impact of cognitive symptoms should be evaluated. Individuals with mild cognitive impairment may have difficulties completing instrumental activities of daily living such as managing finances, cooking, medications, and using transportation.

On neuropsychological testing, individuals with mild neurocognitive disorder perform at least 1 standard deviation below appropriate norms. Of note, a highly educated individual who scores within the normal range on screening tests, for example, a score of 29/30 on the MMSE, may show objective deficits in cognitive function on formal neuropsychological testing, consistent with a diagnosis of MCI.

Dementia, or major neurocognitive disorder, as defined by the Diagnostic and Statistical Manual of Mental Disorders (DSM-5), refers to significant cognitive decline, with impairment in cognitive performance in domains including complex attention, executive function, learning and memory, language, perceptual-motor skills, or social cognition.

On neuropsychological testing, individuals with a major neurocognitive disorder perform 2 or more standard deviations below appropriate norms.

Impairment in activities of daily living include bathing, dressing, grooming, feeding and toileting.

Presumptive causes of cognitive decline include metabolic abnormalities such as hypothyroidism, uncontrolled diabetes, vitamin deficiencies, and/or untreated disorders such as sleep apnea.

Evidence Discussion (HD-8.1)

- The primary role of neuroimaging in the work up of individuals diagnosed with mild cognitive impairment or dementia is to exclude other serious differential diagnosis such as tumors, subdural hematomas, and normal pressure hydrocephalus.[2,3] The American Academy of Neurology (AAN) recommended the use of non-contrast CT or Brain MRI for aiding in the diagnosis of dementia.[3,31] Cross-sectional imaging may also identify characteristic brain atrophy patterns found in common neurodegenerative diseases and vascular insults.[2] CT imaging may also be used when MRI scans are contraindicated.
- Volumetric MRI Brain for the diagnosis of dementia is not currently recommended for routine clinical use by the AAN.[3,31] There remains a significant evidence gap in the literature regarding clinical validation of volumetric MRI in the diagnosis of dementia. Their use remains limited to research studies.[31,32]

Mild Cognitive Impairment (MCI) and Dementia - PET (HD-8.2)

HD.DM.0008.2.A
v2.0.2026

Brain PET CPT® Codes	Definition
78608	Used to report FDG PET metabolic brain studies for dementia, seizure disorders, and brain tumors
78609	Used to report PET brain perfusion studies, primarily used for brain tumors
78811	Limited PET, used for amyloid or tau PET, static imaging to measure amyloid and tau
78814	Limited PET/CT, used for amyloid or tau PET, static images to measure amyloid or tau

Metabolic (FDG) PET Brain CPT® 78608

Amyloid PET Brain CPT® 78814 or 78811

Tau PET Brain CPT® 78814 or 78811

Perfusion PET Brain CPT® 78609

Background and Supporting Information

Evidence Discussion

Metabolic (FDG) PET Brain (CPT® 78608)

Mild Cognitive Impairment

- Metabolic (FDG) PET (CPT® 78608) is medically necessary in the evaluation of for Mild Cognitive Impairment (MCI) when Alzheimer's Disease is suspected and all the following criteria are met:
  - established diagnosis of mild cognitive impairment based on clinical history, physical examination, and cognitive testing, which may include neuropsychological testing.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- documentation of cognitive decline obtained by either:
  - a detailed history of cognitive decline with impairments confirmed by family members or others with knowledge of the individuals status

    OR
  - abnormal mental status test score or neuropsychological test results consistent with mild cognitive impairment/mild neurocognitive disorder
    - examples of abnormal mental status test results consistent with MCI include:
      - Montreal Cognitive Assessment (MOCA) score not < 17
      - Saint Louis University Mental Status (SLUMS) score not < 20
      - Mini Mental State Exam (MMSE) score not < 20
- results of any structural brain imaging (MRI Brain or CT Head) previously performed.

Dementia

- Metabolic (FDG) PET Brain (CPT® 78608) is medically necessary in the evaluation of dementia to distinguish between Alzheimer's disease (AD) and Frontotemporal Dementia (FTD) when all the following criteria are met:
  - Established diagnosis of dementia:
    - date of onset of symptoms with documentation of 6 months of cognitive decline
    - documentation of a decline in cognitive function obtained with either:
      - a detailed history of memory loss with impairment of day-to-day activities confirmed by family members or others with knowledge of the individual's status

        OR
      - abnormal mental status testing score consistent with dementia
        - Examples of abnormal bedside mental status testing scores include:
          - Mini-Mental State Exam (MMSE) <26,
          - Montreal Cognitive Assessment Survey (MoCA) <26,
          - Memory Impairment Screen (MIS) <5,
          - St. Louis University Mental Status (SLUMS) <21, or
          - Eight-item Informant Interview to Differentiate Aging and Dementia (AD8) Dementia Score >2
  - results of any structural imaging (MRI Brain or CT Head) previously performed
  - meets diagnostic criteria for AD and FTD
  - the results are expected to clarify the diagnosis between FTD and AD and help guide future treatment
  - cause of clinical symptoms is uncertain

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- evaluation has ruled out specific alternative neurodegenerative disease or causative factors
  - cannot occur exclusively during bouts of delirium
  - cannot be explained by another mental disorder
- FDG PET brain (CPT® 78608) is otherwise considered not medically necessary for the purpose of diagnosis and management of other forms of dementia including, but not limited to, Parkinson's disease, normal pressure hydrocephalus, and chronic traumatic encephalopathy.
  - For requests related to Lewy Body Dementia, see **Lewy Body Dementia (LBD) – SPECT and PET (HD-8.3)**
- FDG-PET(CPT® 78608)/MRI Brain without contrast (CPT® 70551) OR MRI Brain without and with contrast (CPT® 70553) imaging may be considered on a case-by-case basis for those imaging centers that will utilize FDG-PET/MRI during an initial evaluation (instead of MRI alone) and who also have a standardization of imaging protocol.

Amyloid PET Brain (CPT® 78814 or 78811)

- Amyloid Brain PET is medically necessary when a diagnosis of MCI or dementia due to Alzheimer's disease is suspected based on cognitive testing, and evaluation including structural brain imaging has been completed, in ANY of the following clinical scenarios:
  - individuals with MCI or dementia who are <65 years of age and in whom AD is suspected
  - individuals with MCI or dementia that could be consistent with amnestic AD pathology with onset at ≥65 years of age
  - individuals with MCI or dementia that could be consistent with AD but has atypical clinical features
  - individuals with MCI or dementia with equivocal or inconclusive results on CSF biomarkers
  - to inform the prognosis of individuals with MCI due to suspected AD pathology
  - to determine eligibility for treatment with amyloid targeting therapy and to monitor response see **Imaging Related to Alzheimer's Treatment with Amyloid Reduction Medications (HD-8.5)**

Imaging Related to Alzheimer's Treatment with Amyloid Reduction Medications

For Amyloid PET imaging related to Alzheimer's treatment with amyloid reduction medications see **Imaging Related to Alzheimer's Treatment with Amyloid Reduction Medications (HD-8.5)**

Click Here to Return to the Main TOC

Tau PET Brain (CPT® 78814 or 78811)

- Tau PET is medically necessary for evaluation of cognitive impairment in individuals with suspected AD with atypical clinical presentation when all the following criteria are met:
  - established diagnosis of mild cognitive impairment or dementia
  - evaluation has excluded other causes
  - results of structural brain imaging are available to the ordering provider

See *Background and Supporting Information* regarding suspected AD with atypical presentation .

Perfusion PET Brain (CPT® 78609)

Perfusion PET Brain imaging (CPT® 78609) is not medically necessary in the evaluation of dementia.

- For cerebral amyloid angiopathy, see **Stroke/TIA (HD-21.1)**.

Background and Supporting Information

An atypical clinical presentation of Alzheimer's Disease (AD) is one that meets core clinical criteria of cognitive impairment in multiple domains, which interfere with instrumental activities of daily living and functioning, but has sudden or rapid onset or the onset occurs at a younger age (<65).

Atypical AD variants include:
- Early-onset
- Amnestic variant early-onset AD
- Visuospatial variant AD (posterior cortical atrophy (PCA))
- Language variant AD (lopogenic variant primary progressive aphasia [PPA])
- Behavioral variant/dysexecutive variant AD
- Motor variant AD corticobasal syndrome due to AD

The frontotemporal dementias (FTDs) are a group of neurodegenerative disorders that differ from Alzheimer's disease. The basic pathology involves accumulation of tau proteins in the brain rather than amyloid. Onset tends to be younger (less than 65) and progression usually more rapid than in senile dementia-Alzheimer type (SDAT). There is no treatment, and the medications used to help memory in Alzheimer's disease are not effective.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

There are several subtypes of FTD; most common are the behavioral variant with early loss of executive functions, impaired judgment disinhibition and impulsivity, and the semantic variant with primary and progressive loss of language ability (primary progressive aphasia type FTD). Other less common subtypes include progressive supranuclear palsy, corticobasal syndrome, and FTD associated with motor neuron disease.

Diagnosis of FTD is based on clinical features, neuropsychological testing, and brain imaging (preferably MRI) to rule out other structural disease. Metabolic (FDG) PET Brain is helpful by demonstrating patterns of abnormality more consistent with FTD than Alzheimer's disease.

Recent research has examined the utility of PET/MRI for evaluation of individuals with dementia. Due to the prolonged acquisition time, motion during a PET may lead to artifacts such as blurring of the images. Use of co-registration of PET with MRI can lead to better PET assessment especially with quantitative measurements. Utilization of PET/MRI provides greater confidence in imaging reading by permitting greater structural correlation. A recent study compared FDG-PET/CT and FDG-PET/MRI in a memory disorders clinic. This study identified more individuals with cerebrovascular disease (stroke) and better cortical atrophy characterization. The authors found that PET/MRI provided significant improvement in diagnosis and management of individuals in which dementia is a consideration.

Evidence Discussion (HD-8.2)

The Alzheimer's Association workgroup has revised the criteria for diagnosis and staging of Alzheimer's Disease (AD).[35] The workgroup defined Alzheimer's disease as a biological process, rather than a clinical syndrome, which allows diagnosis in the asymptomatic phase, based on positive biomarkers (Core 1 biomarkers).[35] These Core 1 biomarkers include Amyloid PET and cerebrospinal fluid biomarkers.[35] An abnormal Core 1 biomarker is sufficient to establish a diagnosis of AD.[2,35]

Structural, functional, and molecular brain imaging in individuals with MCI helps to identify potentially treatable structural abnormalities and identify imaging features that may confer an increased risk of transformation to a dementia.[2] In addition, molecular imaging helps inform prognosis, for patients and their families, and allows early treatment initiation.[2,4]

Amyloid PET is positive in 60% of individuals with MCI.[2] Greater cognitive decline is noted in those with MCI and a positive amyloid PET scan, and they are more likely to progress to AD than those with a negative amyloid PET.[2,4] Amyloid PET also results in a change in diagnosis in up to 44% of individuals, therefore increasing diagnostic confidence.[2]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Amyloid PET has a pooled sensitivity of 0.90 and specificity of 0.80 for diagnosis of AD, and a pooled sensitivity of 0.84 and specificity of 0.62 for predicting conversion of MCI to dementia.[36]

Molecular brain imaging is particularly helpful in confirming a diagnosis of AD with atypical clinical presentation.[2] A positive amyloid PET in early-onset or atypical AD can lead to a change in diagnosis of 66.8%, improve confidence in diagnosis in 81.5% and change management in 80% of cases.[2,37] The use of amyloid PET led to changes in management in 63.5% of Medicare members with dementia.[4,5]

The Society of Nuclear Medicine Imaging and Molecular Imaging released Appropriate Use Criteria (AUC) for amyloid PET which included the following clinical scenarios[2,4]:

- Individuals with MCI or dementia who are <65 years of age and for whom AD is suspected
- Individuals with MCI or dementia consistent with amnestic AD pathology with onset ≥65 years of age
- Individuals with MCI or dementia that could be consistent with AD but has atypical features
- Individuals with MCI or dementia with equivocal or inconclusive results on CSF biomarkers
- To inform the prognosis of patients due to suspected AD pathology
- To determine eligibility for treatment with amyloid-targeting therapy and to monitor treatment response

Tau PET is considered appropriate for the evaluation of individuals presenting with MCI or a dementia syndrome that could be consistent with AD pathology but has atypical features.[2,4] In these clinical scenarios, tau uptake correlates with cognitive function and is helpful to diagnose atypical clinical phenotypes of AD.[2]

The work groups supports tau PET in atypical cases as a tau binding pattern can help establish AD as the cause of impairment and the spatial pattern of tau uptake matches brain regions clinically affected.[4] Furthermore, a high tau burden is associated with more rapid clinical progression.[4]

FDG PET Brain in the evaluation of MCI shows a pattern of hypometabolism consistent with AD in up to 79% of cases.[2] In addition, an abnormal pattern predicts conversion from MCI to AD with an accuracy over 80%.[2] Conversely, a negative FDG PET reduces the likelihood of progression to dementia.[2]

FDG-PET brain accurately discriminates Alzheimer's disease individuals from normal subjects with a sensitivity of 96% and specificity of 100%.[2]

Metabolic (FDG) PET brain is helpful by demonstrating patterns of abnormality more consistent with FTD than Alzheimer's disease. FDG PET brain has a sensitivity of 86% and specificity of 97.6% in evaluating individuals with FTD.[2] The use of FDG PET

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

increases diagnostic accuracy and confidence for both AD and FTD.[2] It is particularly helpful in cases of diagnostic uncertainty.[2]

Recent research has examined the utility of PET/MRI for evaluation of individuals with dementia. Due to the prolonged acquisition time, motion during a PET may lead to artifacts such as blurring of the images. Use of co-registration of PET with MRI can lead to better PET assessment especially with quantitative measurements.[23,25] Utilization of PET/MRI provides greater confidence in reading images by permitting greater structural correlation. A recent study compared FDG-PET/CT and FDG-PET/MRI in a memory disorders clinic.[24] The main findings were that FDG PET/MRI revealed more vascular pathology in 35% of individuals, induced a change of the interpretation of FDG PET in 17% of individuals and was considered to influence management in 22% of individuals.[24]

Lewy Body Dementia (LBD) - SPECT and PET (HD-8.3)

HD.DM.0008.3.A
v2.0.2026

SPECT Brain Scan

Metabolic (FDG) PET Brain

Background and Supporting Information

Evidence Discussion (HD-8.3)

SPECT Brain Scan

- SPECT Brain Scan (CPT® 78803 or CPT® 78830) is medically necessary for evaluation of suspected Lewy Body Dementia when all the following are met:
  - Established diagnosis of dementia:
    - date of onset of symptoms with documentation of 6 months of cognitive decline
    - documentation of decline in cognitive function obtained with either:
      - a detailed history of memory loss with impairment of day-to-day activities confirmed by family members or others with knowledge of the individual's status

        OR
      - abnormal mental status test score consistent with dementia or neuropsychological test results consistent with dementia/major neurocognitive disorder
        - examples of abnormal bedside mental status testing scores include:
          - Mini-Mental State Exam (MMSE) <26,
          - Montreal Cognitive Assessment Survey (MoCA) <26,
          - Memory Impairment Screen (MIS) <5,
          - St. Louis University Mental Status (SLUMS) <21, or
          - Eight-item Informant Interview to Differentiate Aging and Dementia (AD8) Dementia >2
  - Presumptive causes of dementia have been excluded
    - cannot occur exclusively during bouts of delirium
    - cannot be explained by another mental disorder

Proprietary Information of UnitedHealthcare.

- Results of any structural imaging (MRI or CT Head) performed

Metabolic (FDG) PET Brain

- Metabolic (FDG) PET brain (CPT® 78608) is medically necessary to differentiate Lewy Body Dementia (LBD) from Alzheimer's Disease (AD) when all the following criteria are met:
  - Established diagnosis of dementia:
    - Date of onset of symptoms with documentation of 6 months of cognitive decline
    - Documentation of decline in cognitive function obtained with either:
      - a detailed history of memory loss with impairment of day-to-day activities confirmed by family members or others with knowledge of the individual's status

        OR
      - abnormal mental status test score consistent with dementia or neuropsychological test results consistent with dementia/major neurocognitive disorder
        - Examples of abnormal bedside mental status testing scores include:
          - Mini-Mental State Exam (MMSE)<26,
          - Montreal Cognitive Assessment Survey (MoCA) <26,
          - Memory Impairment Screen (MIS) <5,
          - St. Louis University Mental Status (SLUMS) <21, or
          - Eight- item Informant Interview to Differentiate Aging and Dementia (AD8) Dementia Score >2
  - Presumptive causes of dementia have been excluded
    - Cannot occur exclusively during bouts of delirium
    - Cannot be explained by another mental disorder
  - Results of any structural imaging (MRI or CT Head) performed

Background and Supporting Information

- Dementia with Lewy bodies is often hard to diagnose because its early symptoms may resemble those of Alzheimer's or a psychiatric illness. Over time people with LBD often develop similar symptoms due to the presence of Lewy bodies in the brain.
  - Clinicians and researchers may use the "1-year rule" to help make a diagnosis. If cognitive, psychiatric, emotional, and/or personality symptoms appear at the same time as or at least a year before movement problems/Parkinsonism, the diagnosis is dementia with Lewy bodies. If cognitive problems develop more than a

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

year after the onset of movement problems, Parkinson's disease, the diagnosis is Parkinson's disease dementia (PDD).

- Core Clinical Symptoms
  - Dementia
  - Movement problems/Parkinsonism
  - Cognitive fluctuations
  - Visual hallucinations
  - REM sleep behavior disorder
- Supportive Clinical Symptoms
  - Extreme sensitivity to antipsychotic medications
  - Falls, fainting
  - Severe problems with involuntary functions (maintaining blood pressure, incontinence, constipation, loss of smell)
  - Changes in personality and mood (depression, apathy, anxiety)

Test Results Supporting Diagnosis

- Abnormal ^{123}iodine-MIBG myocardial scintigraphy showing reduced communication of cardiac nerves
- Sleep study confirming REM sleep behavior disorder without loss of muscle tone

Evidence Discussion (HD-8.3)

- For suspected Lewy Body Dementia (LBD), a CT or MRI head is appropriate as the initial imaging study.[14,31]
- To increase diagnostic accuracy of LBD, SPECT modalities are helpful for differentiating LBD from Alzheimer's dementia.[2,6,14,15]
- Functional imaging of the dopamine transporter (DAT) (Iodine-123 Ioflupane) using SPECT shows a deficiency in the nigrostriatal pathway in LBD. This is considered a second line imaging test after cross-sectional imaging has excluded other pathology, such as vascular lesions along the nigrostriatal pathway, which can lead to abnormal DAT images with false positive results.[14]
- An abnormal DAT-SPECT scan has a sensitivity of 78.7% and a specificity of 90.4% for probable LBD.[2,14]
- Metabolic (FDG) PET imaging demonstrates features which would support a diagnosis of LBD. Hypometabolism in the occipital lobe differentiates LBD[2] from AD.[2,38] In addition, the "cingulate island sign", which refers to the preservation of FDG metabolism in the posterior cingulate gyrus, is considered a biomarker for LBD.[2,39]

Normal Pressure Hydrocephalus (NPH) (HD-8.4)

HD.DM.0008.4.A

v2.0.2026

- CT Head without contrast (CPT® 70450) **OR** MRI Brain without contrast (CPT® 70551) is medically necessary if the individual has at least two symptoms involving gait abnormality (see *Background and Supporting Information*), urinary incontinence, or dementia **AND**
  - The clinical symptoms cannot be completely explained by other neurological or non-neurological disease, **AND**
  - There is no apparent preceding disorder that would cause hydrocephalus
- The components of Dementia are delineated in **Mild Cognitive Impairment (MCI) and Dementia – MRI/CT (HD-8.1)**, but include:
  - Results of testing and/or neuropsychological testing can be performed when history and mental status examination cannot provide a confident diagnosis.
  - Examples of abnormal mental status testing such as Mini-Mental State Exam (MMSE) with score <26, Montreal Cognitive Assessment Survey (MoCA) with score <26, Memory Impairment Screen (MIS) with score <5, the St. Louis University Mental Status (SLUMS) with score <21, or the Eight-item Informant Interview to Differentiate Aging and Dementia (AD8) Dementia Score >2.
  - Presumptive causes or etiology/ies of dementia
    - Cannot occur exclusively during bouts of delirium
    - Cannot be explained by another mental disorder
- MRI Brain (CPT® 70551, CPT® 70552, or CPT® 70553) is not medically necessary for the diagnosis of NPH if a CT has been performed. However, MRI Brain is medically necessary if needed for pre-surgical planning.
  - After neuro imaging, the next steps are CSF sampling, drainage, and dynamics.
- Follow-up imaging for individuals diagnosed with NPH with a shunt should follow **Hydrocephalus Shunts (HD-11.14)**, **Low-Pressure Headache and CSF Leak (HD-11.15)**, or **Nuclear Medicine (HD-36.1)**

Background and Supporting Information

Normal Pressure Hydrocephalus (NPH) seen typically in the elderly. It comprises a triad of symptoms: cognitive dysfunction, incontinence of urine, and gait disturbance (typically a “magnetic”, small-step, shuffling, or broad-based gait). The reported neuroradiologic marker for this is ventriculomegaly (enlarged ventricles) in the brain. Unfortunately, these symptoms and this neuroradiologic finding is common in the elderly, making the

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

diagnosis of NPH in any given individual problematic. It is radiographically common and clinically rare.

Evidence Discussion (HD-8.4)

- Initial neuroimaging for the evaluation of suspected Normal Pressure Hydrocephalus (NPH) includes CT Head or MRI Brain in individuals with clinical symptoms and no explanation for hydrocephalus.[2,21]
- Only a single modality study is medically necessary. The initial best modality is MRI Brain because of its higher intrinsic soft tissue resolution and because it can often be used as a pre-surgical exam.[2,21]
- By using the appropriate single best test, we avoid duplicate imaging and unnecessary radiation to the lens of the eye and other head and neck structures.[2]
- Cine MRI showing hyperdynamic aqueductal CSF flow can also help in identifying shunt-responsive NPH individuals. The benefit of this exam is that it offers us functional information about CSF flow and can help improve individual outcomes.[2,21,34]

Imaging Related to Alzheimer's Treatment with Amyloid Reduction Medications (HD-8.5)

HD.DM.0008.5.A
v2.0.2026

MRI Brain and Amyloid Brain PET are medically necessary to determine eligibility for the treatment of Alzheimer's disease with monoclonal antibodies directed against amyloid (e.g., Donanemab [Kisunla®] and Lecanemab [Leqembi®]) when the following criteria are met:

- Diagnosis of mild cognitive impairment (MCI) or mild dementia due to Alzheimer's disease
- Requested by a neurologist, geriatric psychiatrist or geriatrician
- Change in memory/cognitive function has been present for at least six (6) months
- Baseline MRI brain results are available to the ordering provider
- No intracerebral hemorrhage or vasogenic edema on MRI.
- A bedside cognitive exam score has been obtained and is consistent with MCI or mild AD (i.e., MMSE not < 20, MoCA not < 17, SLUMS not < 20).

ANY of the following imaging studies are medically necessary related to the use of monoclonal antibodies, including Lecanemab (Leqembi®) and Donanemab (Kisunla®), during treatment and to monitor treatment response:

- CT Head without contrast (CPT® 70450)
- MRI Brain without and with contrast (CPT® 70553), MRI Brain without contrast (CPT® 70551), MRI Brain with contrast (CPT® 70552)

Follow-up imaging during treatment, no more often than once every six (6) months:

- Amyloid Brain PET (CPT® 78811 [limited PET] or CPT® 78814 [limited PET/CT])

Background and Supporting Information

Amyloid reduction medications are medically necessary for the treatment of Mild Cognitive Impairment (MCI) due to Alzheimer's disease and mild, early- stage Alzheimer's disease.[25]

These medications are monoclonal antibodies that selectively bind to aggregated forms of beta amyloid. The accumulation of amyloid plaques in the brain is a defining pathophysiologic feature of Alzheimer's disease. In clinical trials, these medications reduce amyloid beta plaque compared with placebo.[25]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Amyloid related imaging abnormalities (ARIA) have been caused by these medications. ARIA usually occurs early in treatment and may be asymptomatic although serious and life-threatening events may occur. Screening MRI Brain prior to treatment initiation and periodic monitoring during treatment is recommended. For moderate to severe ARIA, treatment may be suspended. Once ARIA is identified on a brain MRI, follow up MRIs are medically necessary to assess for radiographic resolution and/or symptom resolution with the imaging time frame determined by the treating physician. Resumption of dosing is guided by clinical judgment.[25]

ARIA may be further characterized as ARIA with edema (ARIA-E) or ARIA with hemosiderin (ARIA-H). ARIA-E presents on MRI as brain edema or sulcal effusions. ARIA-H includes microhemorrhage and superficial siderosis. ARIA-E and ARIA-H may occur simultaneously.[25]

Although ARIA is usually asymptomatic, symptoms associated with ARIA include headache, confusion, visual changes, dizziness, nausea, aphasia, weakness, gait difficulty and seizures, including status epilepticus. Focal neurologic deficits may also occur.[25] The risk of ARIA is increased in apolipoprotein E ε4 (ApoE ε4) homozygotes.[25]

Leqembi® dosing after 18 months may be administered every 2 weeks or transitioned to a maintenance regimen every 4 weeks.

Transitioning from one amyloid targeting monoclonal antibody to another should be done when the individual has been off of the prior drug for 5 half-lives prior to initiation of the alternative drug. The half-life of aducanumab is 24.3 days; the half-life of lecanemab is 9.5 days, and the half-life of donanemab is 11.8 days. Individuals should be off of aducanumab for approximately 4 months or off lecanemab or donanemab for approximately 6 weeks prior to initiation of a different amyloid targeting monoclonal antibody.

Evidence Discussion (HD-8.5)

- Structural brain imaging in the work up of individuals diagnosed with dementia is primarily to exclude other significant intracranial abnormalities. A brain MRI will assist with the diagnosis of dementia by excluding structural pathology such as tumors or subdural hematomas.[2]
- Amyloid related imaging abnormalities (ARIA) have been associated with treatment by amyloid reduction medications. ARIA usually occurs early in treatment and may be asymptomatic although serious and life-threatening events may occur. Screening brain MRI prior to treatment initiation and periodic monitoring during treatment is recommended.[17,27] For moderate to severe ARIA, treatment may be suspended. Once ARIA is identified on a brain MRI, follow- up MRIs are medically necessary to assess for radiographic resolution and/or symptom resolution with the imaging time-frame determined by the treating physician.[17,27] Resumption of dosing is guided by clinical judgment.[17,27]

- Amyloid PET brain is a form of molecular imaging, which uses a tracer that binds to amyloid plaques in the brain. At the present time, the use of Amyloid PET brain is limited to confirming the presence of amyloid in the brain, in those with mild cognitive impairment due to Alzheimer's disease or mild dementia due to Alzheimer's disease, prior to treatment with amyloid reducing medications.

Epilepsy/Seizures (HD-9.1)

HD.EP.0009.1.A
v2.0.2026

- MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) is medically necessary for:
  - evaluation of new onset seizures
  - refractory or drug-resistant seizures
  - new neurologic deficit or no return to previous neurologic baseline
  - change in the type of seizure
  - additional evaluation, if CT Head was performed for an initial evaluation for new onset seizure, MRI (as described above) is medically necessary for additional evaluation
  - follow-up, MRI Brain with “Epilepsy Protocol” is medically necessary
- MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) **OR** CT Head without contrast (CPT® 70450) is medically necessary for:
  - repeat imaging at the discretion of the neurologist or neurosurgeon, or any provider in consultation with a neurologist or neurosurgeon.
- CT Head without contrast (CPT® 70450) is medically necessary for:
  - evaluation of structural findings in seizure etiologies that contain dystrophic calcifications, such as with oligodendrogliomas and tuberous sclerosis
  - acute setting of seizure evaluation
- CT Head (contrast as requested) (CPT®70450, CPT®70460, **OR** CPT®70470) is medically necessary when:
  - MRI is contraindicated
  - request is urgent
- For seizure and/or altered mental status associated with head trauma, see **Head Trauma (HD-13.1)**
- 3D T1 and/or FLAIR sequences are useful in improving lesion detection for the diagnosis and monitoring of epilepsy. 3D T1 and FLAIR sequences do not require an additional CPT® for 3D rendering (CPT® 76376 and CPT® 76377). [12]
- Quantitative Magnetic Resonance Image (MRI) Analysis of the Brain
  - Volumetric or quantitative analysis of the brain or temporal lobes and hippocampus may be requested as (CPT® 0865T or CPT® 0866T)
    - These studies lack sufficient specificity and sensitivity to be clinically useful. Their use is limited to research studies and are not medically necessary in the evaluation of epilepsy.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion (HD-9.1)

- The use of advanced imaging is medically necessary for the initial evaluation of adults with seizure. Unenhanced CT is more readily available so is usually the initial imaging examination performed for adults presenting with first seizure. In the acute setting this primary exam is utilized to exclude conditions requiring urgent or emergent intervention, such as a bleed.[5] CT is also appropriate if MRI is contraindicated and to evaluate seizure foci that contain dystrophic calcifications, such as oligodendrogliomas and tuberous sclerosis, yet the overall success of CT in detecting focal lesions in epilepsy is low, at approximately 30%.[1,5] In studies where individuals were evaluated with both MRI and CT, CT failed to detect potentially epileptogenic lesions identified on MRI 16-42% of the time.[5] Therefore, MRI of the brain is the study of choice to evaluate new-onset seizures (when available), refractory or drug-resistant seizures, prior to discontinuation of anti-epileptic therapy, and known seizure with change in semiology.
- If CT is initially performed, it can be followed by an MRI. If an MRI not using the "Epilepsy Protocol" is initially performed, it can be followed by an MRI with the "Epilepsy Protocol" for greater sensitivity of detection of epileptogenic lesions. The failure rate for detection of lesions improving from 39% to 91% with epilepsy-trained radiologist reading MRI images obtained using a specialized, epilepsy protocol.[1,12,23]

Perioperative Evaluations for Drug-Resistant Epilepsy (HD-9.2)

HD.EP.0009.2.A
v2.0.2026

- **ANY** or **ALL** the following requests are medically necessary, obtained concurrently or sequentially, for consideration of potential surgery:
  - MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553)
    - Follow-up MRI Brain after a previous routine study if performed with special "Epilepsy Protocol" (typically 3T or 7T magnet, thin sections with angled slices through hippocampus and temporal lobes)
  - Metabolic FDG PET (CPT® 78608)
    - Metabolic PET/MRI is MRI Brain without contrast (CPT® 70551) **OR** MRI Brain with and without (CPT® 70553) co-registered **WITH** FDG-PET Brain (CPT® 78608) and is medically necessary for pre-surgical evaluation of refractory seizure when requested by neurosurgeon or neurologist or any provider in consultation with a neurosurgeon or neurologist.
  - Metabolic PET/MRI is MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with (CPT® 70553) co-registered **WITH** FDG-PET Brain (CPT® 78608) and is medically necessary for pre-surgical evaluation of refractory seizure when requested by neurosurgeon or neurologist or any provider in consultation with a neurosurgeon or neurologist.
  - Ictal SPECT (CPT® 78803 or 78830)
  - Functional MRI (fMRI) (CPT® 70555 or CPT® 70554)
    - If MRA Head (CPT® 70544) is medically necessary but Functional MRI (CPT® 70554 or CPT® 70555) was erroneously ordered, then CPT® 70544 may be substituted when appropriate (see **Functional MRI (fMRI) (HD-24.2)**)
  - MRI Brain without contrast (CPT® 70551) **OR** MRI Brain with and without and with (CPT® 70553)
    - Medically necessary if co-registered with Magnetoencephalography (MEG)
  - Quantitative Magnetic Resonance Image (MRI) Analysis of the Brain
    - Volumetric or quantitative analysis of the brain or temporal lobes and hippocampus may be requested as (CPT® 0865T or CPT® 0866T)
      - These studies lack sufficient specificity and sensitivity to be clinically useful. Their use is limited to research studies and are considered not medically necessary in the evaluation of epilepsy.
  - 3D rendering CPT® 76377 (3D rendering requiring image post-processing on an independent workstation) or CPT® 76376 (3D rendering not requiring image post-

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

processing on an independent workstation) is not medically necessary for epilepsy surgery alone, since 3D rendering can be obtained as part of the MRI Brain "Epilepsy Protocol", unless complicated surgical repair considerations involving craniotomy are required.

- When non-invasive EEG monitoring is insufficient, intracranial monitoring with stereo-EEG or grids/strips and depth electrodes is medically necessary with additional imaging for neuronavigation. See **Neurosurgical Imaging (HD-28.1)** and **Neuronavigation (HD-28.2)**
  - Post-operative imaging including after intracranial (EEG) monitoring per neurosurgeon or neurologist or any provider in consultation with neurosurgeon or neurologist.
- See **Primary Central Nervous System Tumors-General Considerations (ONC-2.1)** in the Oncology Imaging Guidelines and/or **Neurosurgical Imaging (HD-28.1)** for additional imaging requests for surgery

Background and Supporting Information

- Magnetoencephalography (MEG) plays an important role in clarifying the significance of abnormalities seen on both structural and functional imaging, for the purpose of epileptogenic zone localization for surgical planning. When used in conjunction with other techniques, MEG plays a major role in the non-invasive epilepsy surgery evaluation. Currently, the guidelines only require review for the MRI co-registered with MEG.
- MEG followed by co-registration with Brain MRI is referred to as Magnetic Source Imaging (MSI)

Below are examples of surgical treatment or an interventional modality that may be under active consideration for individuals with intractable epilepsy (not all inclusive):

- Focal Resection
  - Temporal Lobe Resection
  - Extratemporal Resection
- Lesionectomy
- Multiple Subpial Transections
- Laser Interstitial Thermal Therapy (LITT)
- Anatomical or Functional Hemispherectomy and Hemispherotomy
- Corpus Callosotomy
- Stereotactic Radiosurgery
- Neurostimulation Device Implantations (Neuromodulation) including
  - Vagus Nerve Stimulation (VNS)
  - Responsive Neurostimulation (RNS) system also known as NeuroPace
  - Deep Brain Stimulation (DBS)

Evidence Discussion (HD-9.2)

- MRI Head for the initial imaging of individuals with known seizure disorder requiring surgical planning to identify the seizure focus including tumor, hippocampal sclerosis, and vascular lesions. Follow-up MRI after a previous standard protocol study if performed with special "Epilepsy Protocol" can provide additional information.[1]
- FDG-PET/CT Brain may be complementary as a functional tool to structural imaging using MRI to localize the focus of refractory seizure activity, with reported sensitivities of PET in the assessment of temporal lobe epilepsy ranging from 87% to 90% and extra-temporal lobe epilepsy ranging from 38% to 55%.[1]
- PET/MRI, performed as MRI Brain without contrast, or without and with contrast, co-registered with FDG-PET brain, increased the sensitivity of brain MRI in 60% of non-lesional individuals and is therefore supported for pre-surgical evaluation of refractory seizures.[27]
- Ictal SPECT, Functional MRI (fMRI) and MRI Brain co-registered with Magnetoencephalography (MEG) are also useful to further identify the seizure focus as well as eloquent areas of the cortex that are essential for language, motor function and memory in surgical candidates when done as a replacement for the higher risk Wada test or direct electrical stimulation mapping.[14,15,16]

Trigeminal Neuralgia/Trigeminal Neuropathy (HD-10.1)

HD.TM.0010.1.A

v2.0.2026

- MRI Brain without and with contrast (CPT® 70553) (with special attention to the skull base) or MRI Brain without contrast (CPT® 70551) **AND/OR** facial imaging, MRI Orbit/Face/Neck without contrast (CPT® 70540) or MRI Orbit/Face/Neck without and with contrast (CPT® 70543) is medically necessary for:
  - symptoms of trigeminal neuropathy
  - trigeminal neuralgia
  - trigeminal neuralgia which involves the ophthalmic nerve, (periorbital or forehead pain), once post-herpetic neuralgia (a complication of shingles) has been excluded by history
- CT Maxillofacial without contrast (CPT® 70486) **OR** CT Maxillofacial with contrast (CPT®70487) is medically necessary for evaluating the skull base and neural foramina
- Contrast-enhanced navigation protocol CT (CPT® 76497) is medically necessary for gamma knife stereotactic radiosurgery for trigeminal neuralgia, (see also, **Neuronavigation (HD-28.2)** and **Post-Operative Imaging (HD-28.3)**) for post-treatment imaging studies
- MRI Cervical spine without contrast (CPT® 72141) **OR** MRI Cervical spine without and with contrast (CPT® 72156) is medically necessary for suspected lesion of the spinal trigeminal tract and nucleus.
- MRA Head (CPT® 70544, CPT® 70545 or CPT® 70546) **OR** CTA Head (CPT® 70496) is medically necessary for:
  - trigeminal neuralgia (vascular imaging may be obtained concurrently with structural brain imaging)
  - failed medical treatment
  - surgical planning

Background and Supporting Information

The differential diagnosis of facial pain is extensive, complex, and difficult, and there is considerable case-to-case variation in optimal imaging pathway.

Symptoms of trigeminal neuropathy include facial pain, facial numbness, and/or weakness of the muscles of mastication.

Trigeminal neuralgia, also known as tic douloureux (the involuntary wincing associated with the occurrence of pain), refers to sudden, severe, shooting "electrical" pains along

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

one or more sensory divisions of the trigeminal nerve, provoked by movements such as chewing, or by external stimuli, such as wind blowing or touching the face.

The spinal trigeminal tract and nucleus extend from the midpons caudally into the upper cervical cord at the C2-4 levels. For suspected lesions of the spinal trigeminal tract and nucleus, imaging the brain stem and the cervical spinal cord is supported.

Click Here to Return to the Main TOC

Glossopharyngeal Neuralgia/ Glossopharyngeal Neuropathy (HD-10.2)

HD.TM.0010.2.A

v2.0.2026

- MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551) **AND/OR** MRI Orbit/Face/Neck without and with contrast (CPT® 70543) or MRI Orbit/Face/Neck without contrast (CPT® 70540) is medically necessary for suspected glossopharyngeal neuralgia or neuropathy
- CT Neck with contrast (CPT® 70491) is medically necessary to delineate skull-base erosion, deep space neck masses, calcifications, the skull base bony anatomy, and/or the stylohyoid ligament (see also **Eagle Syndrome (Neck-10.3)**)
- MRA Head with contrast (CPT® 70545), or MRA Head without and with contrast (CPT® 70546), **AND/OR** MRA Neck with contrast (CPT® 70548), or MRA Neck without and with contrast (CPT® 70549) is medically necessary to assess for neurovascular compression for the evaluation of glossopharyngeal neuralgia

Background and Supporting Information

- Glossopharyngeal neuralgia presents as severe pain in the throat and neck, classically triggered by swallowing.
- Glossopharyngeal neuropathy may present with pain, dysphagia, loss of gag reflex, impaired taste, and impaired sensation along posterior one-third of the tongue and/or inability to elevate the palate.

Evidence Discussion (HD-10)

v2.0.2026

- The American Academy of Neurology recommends routine use of MRI in the evaluation of individuals with trigeminal neuralgia.[4] Neuroimaging identifies structural causes in up to 15% of individuals. The most commonly identified abnormalities include cerebellopontine angle tumors and multiple sclerosis plaques.[4]
- MRI brain and/or MRI orbits, face and neck are necessary for direct visualization of the entire course of the trigeminal nerve.[5]
- MRA head, when combined with MRI brain for evaluation of vascular compression of the trigeminal nerve, has sensitivity of 97%-100% and specificity of 100%.[5] CTA is less commonly performed concurrently with MRI of the trigeminal nerve.[5]
- CT maxillofacial may be complementary to MRI in characterizing skull-base erosions, calcifications, and skull-base foramina.
- In the evaluation of glossopharyngeal neuralgia, MRI of the brain and/or MRI orbits, face and neck, allows direct visualization of the entire course of the glossopharyngeal nerve. Imaging should include the pharynx and larynx to exclude a neck mass. To further evaluate bony anatomy, calcifications, and the stylohyoid ligament, CT neck is also appropriate. MRA head and neck is helpful to exclude neurovascular compression in individuals with glossopharyngeal neuralgia.[5]

Headache General Guidelines (HD-11.0)

HD.HA.0011.0.A
v2.0.2026

- MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) or CT Head without contrast (CPT® 70450) are medically necessary for **any** of the following:
  - Headache accompanied by seizures, vomiting, focal neurological complaints including dizziness, visual change, altered mental status, or acute hypertension
  - Abnormal examination findings (including, but not limited to, altered mental status, papilledema, focal signs or symptoms including unilateral weakness or sensory loss, hyperreflexia, clonus, increased tone, Hoffman or Babinski sign, loss of coordination, seizures, gait disturbance, cranial nerve abnormality, vision loss, nystagmus, dysarthria, dysphagia, fever, meningismus)
  - For papilledema, see **Papilledema/Pseudotumor Cerebri (HD-17.1)**)
- Chronic headache with significant change in character, severity, or frequency of headache (for example: progressively worsening headache over a period of days or weeks, transformation of established migraine to chronic daily headaches), the following are medically necessary:
  - MRI Brain without contrast (CPT® 70551) **OR**
  - MRI Brain without and with contrast (CPT® 70553) **OR**
  - CT Head without contrast (CPT® 70450)
  - MRA/MRV Head (CPT® 70544, CPT® 70545, or CPT® 70546) or CTA/CTV Head (CPT® 70496) is medically necessary as an addition to evaluate the recent onset of a progressive, severe, daily headache, with or without papilledema and concern for cerebral venous sinus thrombosis.
    - CT and MR Venography (CTV and MRV) are reported with the same codes as the CTA/MRA counterpart. If arterial and venous CT or MR studies are both performed in the same session, only **ONE** CPT® code should be used to report both procedures.
- Advanced imaging of the head is **NOT** medically necessary for any of the following:
  - Primary headache disorder in the absence of focal neurological deficits or "red flags" (see **Headaches with Red Flags (HD-11.2)** and **Advanced Imaging Indications Related to Migraines (HD-11.17)**)
  - Newly diagnosed migraine or tension-type headache with a normal neurologic exam or for chronic stable headache including migraine with no neurologic deficit.
  - Duplex Ultrasound Carotid Arteries (CPT® 93880) does not have a role in the evaluation of headaches (including migraines), except for suspected carotid dissection (see **Initial Imaging (PVD-3.1)** in the Peripheral Vascular Disease

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Imaging Guidelines, **Headache and Suspected Vascular Dissection (HD-11.1),** and **Stroke/TIA (HD-21.1)**)

Background and Supporting Information

- The yield of detecting abnormal, treatable lesions by CT or MRI in individuals with headache but normal neurological exam has been found to be low.

Health Equity Considerations

Headache disorders, including migraines, are among the most prevalent and disabling neurological conditions, yet their diagnosis and management are marked by significant disparities across racial, socioeconomic, and geographic lines. Despite comparable prevalence rates, historically marginalized populations are less likely to receive accurate diagnoses, evidence-based treatments, and specialist care, resulting in disproportionate burden and reduced quality of life.[45]

Headaches can affect well-being and cause disability, yet the majority of countries face issues with limited access to health care, awareness, and insufficient health policies.[46] Globally, the prevalence of migraines is estimated around 14%, and accounting for 52% of active headache disorders.[45] It is estimated that a headache disorder will affect 90% of individuals during their lifetime.[47] In the U.S., acute headache is the fourth most common reason for a visit to the emergency room.[48]

Racial and ethnic minorities in the U.S. may not receive equitable care when compared to White individuals. For example, Black individuals are 40% less likely to be treated by a neurologist and are more likely to end up in emergency departments for an untreated migraine.[45]

Headache disorders can present within a wide range of severity, which calls for levels of care for headache services.[46] However, a dearth in headache education in medical studies results in inadequate diagnoses and treatment, limiting access to proper care.[46] Telemedicine, which is the remote delivery of healthcare, can allow individuals access to services that may otherwise be inaccessible due to factors such as long waiting times or long-distance travel.[46] However, this requires access to technology and infrastructure, as well as technological literacy, for individuals who may not possess the necessary tools.[46]

HD.HA.0011.1.A

v2.0.2026

- CTA Neck (CPT® 70498) and MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) are medically necessary in the evaluation for headache with suspected carotid or vertebral artery dissection and in certain high-risk scenarios including, but not exclusive to: Fibromuscular dysplasia (FMD), Marfan disease, acute MVA with whiplash, and acute headache and/or neck pain due to chiropractic manipulation.
  - CTA Head (CPT® 70496) or MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) is medically necessary if there is concern for extension of a carotid dissection to the skull base or above. CTA Head and Neck (CPT® 70471) must be substituted when both CTA Head (CPT® 70496) and CTA Neck (CPT® 70498) are performed during the same session.
  - Evaluation of posterior circulation disease requires both neck and head MRA/CTA to visualize the entire vertebro-basilar system.
- MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) or CTA Neck (CPT® 70498) is medically necessary if arterial dissection is suspected, or known and re-evaluation is needed (as directed by neurologist or neurosurgeon or any provider in consultation with a neurologist or neurosurgeon).
- MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) or CTA Head (CPT® 70496, or CPT® 70498) is medically necessary if arterial dissection is suspected, or known and re-evaluation is needed (as directed by neurologist or neurosurgeon or any provider in consultation with a neurologist or neurosurgeon)
- Other vascular imaging indications for headaches require additional information.
  - See **Stroke/TIA (HD-21.1)**, **Sudden Onset of Headache (HD-11.3)**, **New Headache Onset Older than Age 50 (HD-11.7)**, **Abnormal Blood Clotting (HD-11.9)**, **Pregnancy (HD-11.10)**, **Physical Exertion (HD-11.11)**, and **Systemic Infections (HD-11.13)**

Headaches with Red Flags (HD-11.2)

HD.HA.0011.2.A
v2.0.2026

- Headaches with any of the following Red Flags:
  - If any of the below unusual symptoms or history are present, advanced imaging studies are medically necessary (see relevant section):
    - Cancer history or immunosuppression (see **Cancer or Immunosuppression (HD-11.8)**)
    - Sudden onset (see **Sudden Onset of Headache (HD-11.3)**)
    - New onset age >50 (see **New Headache Onset Older than Age 50 (HD-11.7)** and **Migraine Exceptions (HD-11.17)**)
    - History of head trauma (see **Headaches Associated with Head Trauma (HD-11.12)**, and **Head and Facial Trauma (HD-13)**)
    - Headache precipitated by cough or Valsalva, physical exertion, or sexual activity (see **Physical Exertion (HD-11.11)**)
    - Currently pregnant (including pregnancy and the immediate postpartum period) (see **Pregnancy (HD-11.10)**)
    - Hypercoagulable state or bleeding disorder (see **Abnormal Blood Clotting (HD-11.9)**)
    - New persistent headache (see **Migraine Exceptions (HD-11.17)**)
    - Headache awakens individual from sleep (see **Sudden Onset of Headache (HD-11.3)**)

Background and Supporting Information

Aura symptoms may accompany or precede a headache within 60 minutes and may include, but are not exclusive to, the following symptoms:

- Visual (flashing lights, loss of vision)
- Sensory (paresthesia)
- Speech and/or language (difficulty speaking)
- Motor (any weakness)
- Brainstem (dizziness, double vision) and retinal (visual complaints)

Sudden Onset of Headache (HD-11.3)

HD.HA.0011.3.A
v2.0.2026

- For sudden onset of headache including:
  - worst, most severe headache ever experienced or thunderclap-type (example: awakening from sleep)
  - sudden onset unilateral headache, suspected carotid or vertebral dissection or ipsilateral Horner's syndrome
  - consideration of reversible cerebral vasoconstriction syndrome (RCVS) (typically bilateral headache)
  - high-risk scenarios including Fibromuscular Dysplasia (FMD), Marfan Disease, MVA with whiplash, and chiropractic manipulation
- If any of these onset of headache features are present, the following are medically necessary:
  - CT Head without contrast (CPT® 70450) **OR** MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) **AND/OR**
  - CTA Head (CPT® 70496) **or** MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546)
  - MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) **OR** CTA Neck (CPT® 70498) if carotid or vertebral artery dissection is suspected
    - CTA Head and Neck (CPT ® 70471) combination code must be substituted when both CTA Head (CPT® 70496) and CTA Neck (CPT® 70498) are performed in the same session.
    - CT and MR Venography (CTV and MRV) are reported with the same codes as the CTA/MRA counterpart. If arterial and venous CT or MR studies are both performed in the same session, only **ONE** CPT® code should be used to report both procedures
- Repeat MRI Brain and/or MRA/CTA Head and Neck imaging is medically necessary in 2-4 weeks if suspicion of Reversible Cerebral Vasoconstriction Syndrome (RCVS) is high and to follow up until resolution of vasospasm, edema and/or hemorrhage, at the discretion of the neurologist, neurosurgeon, hematologist, or physiatrist, or any provider in consultation with a neurologist, neurosurgeon, hematologist, or physiatrist
- MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) or CTA Neck (CPT® 70498) is medically necessary if arterial dissection is suspected, or known and re-evaluation is needed (as directed by neurologist or neurosurgeon or any provider in consultation with a neurologist or neurosurgeon)
- MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) or CTA Head (CPT® 70496, CPT® 70498) is medically necessary if arterial dissection is suspected, or known and

Proprietary Information of UnitedHealthcare.

re-evaluation is needed (as directed by neurologist or neurosurgeon or any provider in consultation with a neurologist or neurosurgeon)

- CTA Head and Neck (CPT ® 70471) combination code must be substituted when both CTA Head (CPT® 70496) and CTA Neck (CPT® 70498) are performed in the same session
- Other vascular imaging indications for headaches require additional information.
  - See **Stroke/TIA (HD-21.1)**, **New Headache Onset Older than Age 50 (HD-11.7)**, **Abnormal Blood Clotting (HD-11.9)**, **Pregnancy (HD-11.10)**, **Physical Exertion (HD-11.11)**, **Cerebral Aneurysms (HD-12.1)** and **Systemic Infections (HD-11.13)**

Trigeminal Autonomic Cephalgias (HD-11.4)

HD.HA.0011.4.A
v2.0.2026

- For trigeminal autonomic cephalgias and cluster headache, the following are medically necessary:
  - MRI Brain without and with contrast (CPT® 70553) **OR**
  - MRI Brain without contrast (CPT® 70551)
  - May also include pituitary screening (see **Pituitary, Sella, Hypothalamus (HD-19)**)
- For facial pain (see **Trigeminal Neuralgia and other Centrally Mediated Facial Pain Syndromes (HD-10))**

Background and Supporting Information

Trigeminal autonomic cephalgias includes cluster headache, short-lasting, unilateral, neuralgiform headache attacks with conjunctival injection and tearing (SUNCT) syndromes; short-lasting unilateral neuralgiform headache attacks with cranial autonomic symptoms (SUNA) and hemicrania paroxysmal and continua.

Skull Base, Orbit, Periorbital or Oromaxillary (HD-11.5)

HD.HA.0011.5.A

v2.0.2026

- Skull base, orbital, periorbital or oromaxillary imaging is medically necessary for concern of skull base tumors in individuals with head and neck cancers, other skull base abnormalities seen on previous imaging, any invasive sinus infections as well as sinus tumors or orbital tumors with intracranial extension.
- In these clinical scenarios, the following studies are medically necessary:
  - MRI Brain and/or Orbits/Face/Neck without and with contrast (CPT® 70553 and/or CPT® 70543) **OR**
  - MRI Brain and/or Orbits/Face/Neck without contrast (CPT® 70551 and/or CPT® 70540) **OR**
  - CT Head and/or Orbits/Temporal bone without and with contrast (CPT® 70470 and/or CPT® 70482) **OR**
  - CT Head and/or Orbits/Temporal bone with contrast (CPT® 70460 and/or CPT® 70481)

Proprietary Information of UnitedHealthcare.

Suspected Intracranial Extension of Sinusitis or Mastoiditis (HD-11.6)

HD.HA.0011.6.A

v2.0.2026

- For suspected intracranial extension of sinusitis or mastoiditis, the following is medically necessary:
  - MRI Brain without and with contrast (CPT® 70553)
  - See **Mastoid Disease or Ear Pain (HD-26.1)** and **Skull Base, Orbit, Periorbital or Oromaxillary (HD-11.5)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

New Headache Onset Older than Age 50 (HD-11.7)

HD.HA.0011.7.A

v2.0.2026

- For new onset headache in individuals older than 50 years of age, the following are medically necessary:
  - MRI Brain without contrast (CPT® 70551) **OR**
  - MRI Brain without and with contrast (CPT® 70553) **OR**
  - CT Head without contrast (CPT® 70450)
  - If Giant Cell Arteritis, also known as Temporal Arteritis, is suspected, MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546), see **Cerebral Vasculitis (HD-22)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Cancer or Immunosuppression (HD-11.8)

HD.HA.0011.8.A

v2.0.2026

- For new headache in individuals with cancer, history of cancer, or those who are immunocompromised, the following are medically necessary:
  - MRI Brain without contrast (CPT® 70551) **OR**
  - MRI Brain without and with contrast (CPT® 70553)
- For CT imaging in the setting of individuals with cancer, with history of cancer or who are immunocompromised, see **General Guidelines – CT Head (HD-1.4)**
- See also **Primary Central Nervous System Tumors – General Considerations (ONC-2.1)** and **Brain Metastases (ONC-31.3)**

Proprietary Information of UnitedHealthcare.

Abnormal Blood Clotting (HD-11.9)

HD.HA.0011.9.A

v2.0.2026

- MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) **OR** CT Head without contrast (CPT® 70450) is medically necessary for:
  - new onset headaches in individual with hypercoagulable states or bleeding disorder
    - MRA/MRV Head (CPT® 70544, CPT® 70545, or CPT® 70546) or CTA/CTV Head (CPT® 70496) is medically necessary, in addition, for venogram when requested.
      - CT and MR Venography (CTV and MRV) are reported with the same codes as the CTA/MRA counterpart. If arterial and venous CT or MR studies are both performed in the same session, only **ONE** CPT® code should be used to report both procedures
  - individuals with potential for bleeding diathesis
    - Taking anticoagulants or two or more anti-aggregants or having a medical condition that predisposes to bleeding (for example, but not limited to: thrombocytopenia, liver failure, idiopathic thrombocytopenic purpura (ITP), etc.).

Proprietary Information of UnitedHealthcare.

Pregnancy (HD-11.10)

HD.HA.0011.10.A

v2.0.2026

- For new onset headache during pregnancy or immediate post-partum period (within 3 months after delivery), ANY or ALL of the following are medically necessary:
  - MRI Brain without contrast (gadolinium relatively contraindicated in pregnancy) (CPT® 70551)
  - CT Head without contrast (CPT® 70450) if urgent
  - MRA/MRV Head (CPT® 70544, CPT® 70545, or CPT® 70546) or CTA/CTV Head (CPT® 70496) when venogram is requested
    - CT and MR Venography (CTV and MRV) are reported with the same codes as the CTA/MRA counterpart. If arterial and venous CT or MR studies are both performed in the same session, only one CPT® code should be used to report both procedures. (gadolinium relatively contraindicated in pregnancy)
    - Vascular imaging is medically necessary concurrently with brain imaging
- Important causes of secondary headache include vascular disorders, such as pre-eclampsia, reversible cerebral vasoconstriction syndrome, and cerebral venous thrombosis, as well as idiopathic intracranial hypertension
- For post-LP/epidural anesthesia, see **Low-Pressure Headache and CSF Leak (HD-11.15)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Physical Exertion (HD-11.11)

HD.HA.0011.11.A

v2.0.2026

- For onset of headache with Valsalva maneuver, cough, physical exertion, change in position, **or** sexual activity, but not merely a worsening of a pre-existing headache with these activities, the following procedures are medically necessary:
  - MRI Brain without contrast (CPT® 70551) **OR**
  - MRI Brain without and with contrast (CPT® 70553) **OR**
  - CT Head without contrast (CPT® 70450) **AND/OR**
  - MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **OR**
  - CTA Head without and with contrast (CPT® 70496)
  - MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) or CTA Neck (CPT® 70498) if carotid or vertebral artery dissection or aneurysm is suspected
    - CTA Head and Neck (CPT ® 70471) combination code must be substituted when both CTA Head (CPT® 70496) and CTA Neck (CPT® 70498) are performed in the same session.

Headaches Associated With Head Trauma (HD-11.12)

HD.HA.0011.12.A

v2.0.2026

- For new or progressively worsening headache with subacute head trauma, defined as within 7 days to three months post-trauma, with or without unexplained cognitive or neurologic deficits, the following are medically necessary:
  - CT Head without contrast (CPT® 70450) **OR**
  - MRI Brain without contrast (CPT® 70551)
- For persistent headaches attributed to traumatic injury to the head persisting for longer than 3 months following the injury, with or without unexplained cognitive or neurologic deficits, the following are medically necessary:
  - MRI Brain without contrast (CPT® 70551) **OR**
  - MRI Brain without and with contrast (CPT® 70553)
- Acute head trauma with headache, (see **Head Trauma (HD-13.1))**
- Acute headache attributed to traumatic injury to the head that developed within 7 days of injury that does not meet criteria under **Head and Facial Trauma (HD-13)**, other subsections may apply including, but not exclusive to: **Headaches with Red Flags (HD-11.2)** and **Sudden Onset of Headache (HD-11.3)**

Systemic Infections (HD-11.13)

HD.HA.0011.13.A

v2.0.2026

- For headaches in the setting of acute, subacute, or chronic systemic infections, the following are medically necessary:
  - MRI Brain without contrast (CPT® 70551); or MRI Brain without and with contrast (CPT® 70553)
  - MRA/MRV Head (CPT® 70544, CPT® 70545, or CPT® 70546)
    - CT and MR Venography (CTV and MRV) are reported with the same codes as the CTA/MRA counterpart. If arterial and venous CT or MR studies are both performed in the same session, only one CPT® code should be used to report both procedures
  - CT Head without contrast (CPT® 70450) or CT Head without and with contrast (CPT® 70470), when MRI Brain is contraindicated (see **General Guidelines – CT Head (HD-1.4)** for additional CT Head indications)
  - CT Head without (CPT® 70450) prior to performance of lumbar puncture (aka spinal tap)
- See **CNS and Head Infection (HD-14.1)**
- See **Neuro-COVID-19 and Sars-CoV-2 Vaccines (HD-14.2)** for headache related to neuro-COVID-19 or SARS-CoV-2 vaccines

Hydrocephalus Shunts (HD-11.14)

HD.HA.0011.14.A
v2.0.2026

Initial Imaging Indications

- MRI Brain without and with contrast (CPT® 70553) is medically necessary

Repeat Imaging Indications including CSF flow shunting and Ventriculostomy

- MRI Brain without contrast (CPT® 70551) or CT Head without contrast (CPT® 70450) is medically necessary for any of the following:
  - New signs or symptoms suggesting shunt malfunction or endoscopic third ventriculostomy (ETV) malfunction
    - Symptoms may include but are not limited to: sepsis after shunt setting adjustments, decreased level of consciousness, protracted vomiting, visual or neurologic deterioration, decline of mentation after initial improvement, or new or changing pattern of seizures
  - Requests ordered by a neurologist, neurosurgeon, or any provider in consultation with a neurologist or neurosurgeon
- MRI Brain without contrast (CPT® 70551) or CT Head without contrast (CPT® 70450) is medically necessary in the post-operative period following shunt placement or ETV, with further follow-up imaging 6-12 months after the procedure and then every 12 months for individuals with stable clinical findings
- Shunting into the peritoneum (VP shunts) can give rise to abdominal complications, but these are generally symptomatic, so surveillance imaging of the abdomen is not medically necessary unless ordered by or in consultation with neurology, neurosurgery, or interventional radiology.
  - Abdominal ultrasound (CPT® 76700) **AND/OR** CT Abdomen or CT Abdomen/Pelvis (contrast as requested), is medically necessary depending on the clinical suspicion
    - Examples include, but are not limited to, suspicion of CSF pseudocyst formation, distal shunt outlet obstruction, or infection.
- See **General Guidelines – Other Imaging Situations (HD-1.7)**

Additional Rarely Used Studies

- Cisternogram (CPT® 78630) is medically necessary for the following:
  - Known hydrocephalus with worsening symptoms.
  - Suspected obstructive hydrocephalus.
  - Suspected normal pressure hydrocephalus with gait disturbance and either dementia or urinary incontinence.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - For indications related to CSF Leak, (see **Low-Pressure Headache and CSF Leak (HD-11.15)** and **Nuclear Medicine (HD-36.1)**)
- Cerebrospinal Ventriculography (CPT® 78635) is medically necessary for the following:
  - Evaluation of internal shunt, porencephalic cyst, or posterior fossa cyst.
- Nuclear Medicine Shunt Evaluation (CPT® 78645) and CSF Flow SPECT (CPT® 78803) is medically necessary for the following:
  - Suspected malfunction of ventriculoperitoneal, ventriculopleural, or ventriculovenous shunts.
- For CSF flow imaging, see **CSF Flow Imaging (HD-24.4)**
- See also **General Guidelines - CT Head (HD-1.4)**

Background and Supporting Information

- Ventriculomegaly is the condition where ventricles are enlarged, and this may be due to 1) hydrocephalus, a condition of increased intracranial pressure (ICP) (imaging shows ventricles are disproportionately enlarged compared to sulci), or 2) brain atrophy, most commonly related to age or trauma, which is not associated with increased ICP (imaging shows ventricles and sulci are proportionately enlarged).
- Hydrocephalus is divided into obstructive/non-communicating vs. communicating types, and these usually have different etiologies and radiographic features.
- Obstructive or non-communicating hydrocephalus classically involves an intraventricular obstruction in which CSF flow over the convexities and between the ventricles is reduced, and the proximal ventricle(s) is/are dilated. This is a medical emergency.
- Communicating hydrocephalus involves extraventricular obstruction, poor absorption, or overproduction of CSF. There is normal intracranial CSF flow and absence of disproportionate ventricular dilation, yet there is still a mildly increased CSF pressure. Normal pressure hydrocephalus is an example of this type.
- Distinguishing between ventriculomegaly due to brain atrophy and non-communicating hydrocephalus can be difficult with MRI Brain or CT Head alone, and modalities which visualize CSF flow may be useful such as cisternography or CT cisternography.

Proprietary Information of UnitedHealthcare.

Low-Pressure Headache and CSF Leak (HD-11.15)

HD.HA.0011.15.A

v2.0.2026

- Evaluation of suspected CSF leak (rhinorrhea/otorrhea) or refractory post-lumbar puncture headache, post-spinal surgery headache, orthostatic headache, or low-pressure headache:

Indication	Medically Necessary Imaging
Intracranial imaging	• MRI Brain without contrast (CPT® 70551) or • MRI Brain without and with contrast (CPT® 70553)
Spinal imaging (MRI)	• MRI Cervical Spine without contrast (CPT® 72141) or without and with contrast (CPT® 72156) **AND/OR** • MRI Thoracic Spine without contrast (CPT® 72146) or without and with contrast (CPT® 72157) **AND/OR** • MRI Lumbar Spine without contrast (CPT® 72148) or without and with contrast (CPT® 72158)
Spinal imaging, post-myelogram	• CT Cervical Spine with contrast (CPT® 72126) **AND/OR** • CT Thoracic Spine with contrast (CPT® 72129) **AND/OR** • CT Lumbar Spine with contrast (CPT® 72132)
Spinal imaging, MR myelogram	• MRI Spine, contrast as requested • Requests following initial negative/non-diagnostic MRI Spine and MRI Brain are also medically necessary
Cisternogram, radionucleotide (111 In-DTPA)	• Radionucleotide cisternogram (CPT® 78630)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging
Cisternogram, post-myelogram (iodinated contrast)	• CT Head with contrast (CPT® 70460) **OR** • CT Maxillofacial with contrast (CPT® 70487) **OR** • CT Temporal Bone with contrast (CPT® 70481)
Symptoms of CSF rhinorrhea or otorrhea	• CT Head without contrast (CPT® 70450) **AND/OR** • CT Maxillofacial without contrast (CPT® 70486) **OR** • CT Temporal Bone without contrast (CPT® 70480)

- Additional Cisternogram (CPT® 78630) indications:
  - Known hydrocephalus with worsening symptoms (for example headache)
  - Suspected obstructive hydrocephalus
- Individuals with a Shunt (see **Hydrocephalus Shunts (HD-11.14)**)

Background and Supporting Information

- Common radiological findings of CSF leaks include abnormalities of the cribriform plate or ethmoid sinus, dural dehiscence at the anterior skull base, pneumatization of the sphenoid sinus, and fluid within the middle ear.
- CSF leaks may occur in:
  - CSF shunt over-drainage
  - traumatic CSF leaks
    - Thecal holes and rents from lumbar punctures and epidural catheterizations
    - Spinal and cranial surgeries including skull base and some sinus surgeries
    - Proximal brachial plexus and nerve root avulsion injuries
  - Spontaneous leaks may occur in, but are not exclusive to:
    - Pre-existing weakness of the dural sac including:
      - disorders of connective tissue matrix including Marfan syndrome, Marfanoid features
      - joint hypermobility
    - Trivial trauma in the setting of preexisting dural weakness
    - Spondylotic spurs, herniated discs

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Cervicogenic Headaches Including Occipital Neuritis/Neuralgia (HD-11.16)

HD.HA.0011.16.A
v2.0.2026

- Brain imaging should follow applicable sections in **Headache (HD-11)**
- MRI Cervical Spine without contrast (CPT® 72141) is medically necessary for:
  - failure of 6-week trial of provider-directed treatment after the current set of symptoms or physical exam findings started or changed and clinical re-evaluation after treatment period (unless presence of a red flag) as defined in **Red Flag Indications (SP-1.2)**
    - See **Neck (Cervical Spine) Pain Without/With Neurological Features (Including Stenosis) (SP-3.1)** and **Neck (Cervical Spine) Trauma (SP-3.2)** in the Spine Imaging Guidelines
    - Exemptions to the 6 weeks of conservative care include:
      - high-risk mechanism of cervical spine injury within the last 3 months (see **Neck (Cervical Spine) Trauma (SP-3.2)** in the Spine Imaging Guidelines)
      - **Red Flag Indications (SP-1.2)** in the Spine Imaging Guidelines
      - **ANY** of the following:
        - Bony abnormalities: Atlanto-axial dislocations/instability (including but not limited to: Down's syndrome, Ehlers-Danlos and Marfan syndromes and rheumatoid arthritis), platybasia, osteomas, callous formation of the posterior C1/2 arches
        - Posterior fossa lesions, Chiari malformations, demyelinating disease
        - Myelopathy/myelitis (see **Myelopathy (SP-7.1)** in the Spine Imaging Guidelines)

Background and Supporting Information

- Cervicogenic Headache
  - Headache caused by a disorder of the cervical spine, usually accompanied by neck pain or other signs and symptoms of cervical disease. Typical findings include reduced cervical range of motion, side-locked pain, and symptoms exacerbated by provocative maneuvers such as head movement or digital pressure.
- Occipital Neuralgia/Neuritis - Occipital neuralgia is classified unilateral or bilateral paroxysmal, shooting or stabbing pain in the posterior part of the scalp, in the distribution(s) of the greater, lesser and/or third occipital nerves, sometimes accompanied by diminished sensation or dysaesthesia in the affected area and commonly associated with tenderness over the involved nerve(s).

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Pain has at least two of the following three characteristics:
  - Recurring in paroxysmal attacks lasting from a few seconds to minutes
  - Severe in intensity
  - Shooting, stabbing or sharp in quality
- Pain is associated with both of the following:
  - Dysaesthesia and/or allodynia apparent during innocuous stimulation of the scalp and/or hair
  - Either or both of the following:
    - Tenderness over the affected nerve branches
    - Trigger points at the emergence of the greater occipital nerve or in the distribution of C2
- Pain is eased temporarily by local anesthetic block of the affected nerve(s)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Advanced Imaging Indications Related To Migraines (HD-11.17)

HD.HA.0011.17.A
v2.0.2026

- Advanced imaging of the head is **NOT** medically necessary for newly diagnosed migraine with a normal neurological exam or chronic stable migraine with no neurological deficit and/or no red flags (see **Headaches with Red Flags (HD-11.2)**).
  - See below for advanced imaging indications related to migraines.
- New migraine with age ≥50 (see **New Headache Onset Older than Age 50 (HD-11.7)**)
- Change in frequency or severity of migraine (see **Headaches with Red Flags (HD-11.2)**)
- MRI Brain without (CPT® 70551) or MRI Brain without and with (CPT® 70553) or CT Head without (CPT® 70450) for the following:
  - Unusual, prolonged, or persistent aura (greater than 60 minutes) (See *Background and Supporting Information*)
  - Worst migraine
  - Hemiplegic migraine
    - Migraine with any motor weakness.
  - Migrainous accompaniments
    - Passing neurological symptoms that can affect vision, speech, movement, and behavior-“mimic stroke”
  - Migraine aura without headache
    - Migraine with an aura in which the aura is neither accompanied nor followed by a headache within 60 minutes.
  - Side-locked migraine (unilateral)
    - Unilateral hemicranial pain – includes primary and secondary causes.
      - New daily persistent headache (new daily headache present greater than three months)
      - Trigeminal autonomic cephalgias includes cluster headache short-lasting, unilateral, neuralgiform headache attacks with conjunctival injection and tearing (SUNCT) syndromes; short-lasting unilateral neuralgiform headache attacks with cranial autonomic symptoms (SUNA) and hemicrania paroxysmal and continua are covered in **Trigeminal Autonomic Cephalgias (HD-11.4)**
  - Post-traumatic migraine
    - See **Head Trauma (HD-13.1)** and **Headaches Associated with Head Trauma (HD-11.12)**

Background and Supporting Information

- Aura symptoms may accompany or precede a headache within 60 minutes and may include, but are not exclusive to, the following symptoms:
  - Visual (flashing lights, loss of vision)
  - Sensory (paresthesia)
  - Speech and/or language (difficulty speaking)
  - Motor (any weakness)
  - Brainstem (double vision) and retinal (visual complaints)

Evidence Discussion (HD-11)

v2.0.2026

- The majority of headaches are due to benign causes and are self-limited. The yield of positive findings on a CT Head for evaluation of headache in the emergency department setting ranged from 7% to 13%.[1]
- The American College of Radiology in the Choosing Wisely campaign recommended against imaging for primary headache syndromes in the absence of red flags and with a normal neurologic exam.[1,32] The American Headache Society and Choosing Wisely Task Force stated that the overuse or misuse of imaging studies for headache was the most commonly mentioned problem.[32] Overuse of CT Head was identified as the main concern.[32] The authors note that a single CT scan of the head exposes individuals to an average of 2 millisievert (mSV) of radiation, the equivalent of 8 months of background radiation.[32]
- Incidental findings are common and can result in anxiety for the individual, additional referrals and specialist consults, and more imaging studies.[30,31] Incidental findings on MRI occur in 2% of the general population.[31]
- The American Headache Society and the American Academy of Neurology recommended neuroimaging in individuals with headaches with atypical features, "red flags", and/or abnormal neurologic exam findings.[1,13,29]
- The presence of neurologic or systemic signs, new headaches over age 50, or headaches in the setting of malignancy or immunosuppression, always require further evaluation with advanced imaging, and are considered "red flags," due to the higher likelihood of intracranial pathology.[1,30,36,37] CT Head in the presence of "red flags" is helpful to exclude intracranial hemorrhage.[1] However, MRI Brain has higher contrast resolution than CT Head and is preferred for evaluation of structural pathologies, particularly in non-urgent settings.[1]
- Subarachnoid hemorrhage due to ruptured cerebral aneurysm accounts for 4%-12% of acute severe headaches.[1] CT Head is medically necessary as initial imaging for thunderclap headache. CT Head had a negative predictive value between 99.9%-100% in detecting aneurysmal subarachnoid hemorrhage within 6 hours of headache onset. The sensitivity is over 90% when CT Head is performed within the first 24 hours. CT Angiography (CTA) Head obtained concurrently or in follow up may identify cerebral aneurysm, dissection, and reversible cerebral vasoconstriction syndrome.[1]
- In selected cases, CT Head is supported for evaluation and follow up of headache caused by subdural or epidural hemorrhage, skull fracture, sinus infection or subarachnoid hemorrhage.[30]
- New headaches in the setting of pregnancy and the postpartum period require special consideration.[1,30,35]

Click Here to Return to the Main TOC

- Over a third of pregnant women presenting to the hospital with headache have a secondary cause.[1,34,35] Of individuals with headache in the immediate postpartum period, 41% had an abnormal MRI Brain.[35]
- Imaging in this scenario includes MRI Brain, MR Venogram (MRV) Head, and/or MR Angiography (MRA) Head. Gadolinium contrast is relatively contraindicated during pregnancy and should be avoided.[1]
- Trigeminal autonomic cephalgias, including cluster headaches, are required to have MRI brain to exclude pathology in the pituitary region.[1,30] MRI should include the brain and the pituitary region.[1,13]
- Headaches concerning for raised intracranial pressure or intracranial hypotension, required additional evaluation with neuroimaging.[1,30] To exclude hydrocephalus, a mass, or cerebral venous sinus thrombosis, MRI Brain, Orbits, and Venogram are medically necessary in the setting of papilledema and/or intracranial hypertension.[1,30] In urgent cases, a CT Head can rapidly diagnose causes such as mass, edema, or hydrocephalus.[1]
- MRI is also useful to evaluate for structural causes of headache due to intracranial hypotension and cerebrospinal (CSF) leaks.[1,30] Depending on the suspected source of the leak, imaging the brain and spinal cord may be required. Spinal imaging may include MRI of the spinal cord, or CT myelogram.[1]
- In the evaluation of headaches from suspected intracranial hypotension with negative initial brain and spine imaging, and high clinical suspicion of a CSF leak, MR myelography is indicated to detect subtle spinal leak sources, such as CSF-venous fistulas and slow meningeal diverticular leaks.[41]
- CTA Head or MRA Head in the evaluation of headache are medically necessary for suspicion of carotid or vertebral arterial dissections, AVMs and cerebral aneurysm, as secondary causes of headache.[1]
- CT Venogram (CTV) head or MRV head in the evaluation of headache are supported for suspicion of cerebral venous sinus thrombosis or stenosis in select cases, included suspected headache associated with pregnancy and the post-partum period, headache with papilledema, intracranial hypertension, and the trigeminal autonomic cephalgias.[1]
- Computerized tomography (CT) is the gold standard for the evaluation of abdominal complications related to ventriculoperitoneal shunts (VPS).[38]

Cerebral Aneurysms (HD-12.1)

HD.AN.0012.1.A
v2.0.2026

Disorders and Indications (Any of the following)	Medically Necessary Imaging
Coarctation of the aorta	See **Aortic Coarctation and IAA (interrupted aortic arch) (PEDCD-2.4.11)**
Screening for high-risk populations as defined by the following criteria (screening usually begins at age 20 unless unusual circumstances as aneurysms are uncommon in children and adolescents): • Positive Family History: Two or more first degree relatives (parent, sibling, or child) with history of cerebral aneurysm or subarachnoid hemorrhage (SAH): screening every 5 years beginning at age 20. One first degree relative (parent, sibling, or child) with history of cerebral aneurysm or SAH can have one screening study • Autosomal dominant polycystic kidney disease (screening begins at age 20 to 65 and is repeated at five-year intervals) • Alpha-1-antitrypsin deficiency • Alpha-glucosidase deficiency • Azygos anterior cerebral artery (presence of) • Bicuspid aortic valve • Fibromuscular dysplasia (one screening study after confirmed diagnosis) • Ehlers-Danlos Syndrome Type 4 (Vascular) • Glucocorticoid-remediable aldosteronism (GRA) • Hereditary hemorrhagic telangiectasia (Osler-Weber-Rendu Syndrome) See **Screening for Vascular related genetic connective tissue Disorders (PVD-2.2)**	• CTA Head (CPT® 70496) **OR** • MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Disorders and Indications (Any of the following)	Medically Necessary Imaging
Screening for high-risk populations as defined by the following criteria (screening usually begins at age 20 unless unusual circumstances as aneurysms are uncommon in children and adolescents) - ***CONTINUED***: • Kawasaki disease • Klinefelter syndrome • Klippel-Trenaunay-Weber Syndrome • Loeys-Dietz Syndrome • Marfan Syndrome • Microcephalic osteodysplastic primordial dwarfism • Neurofibromatosis Type 1 • Noonan Syndrome • Pheochromocytoma • Pseudoxanthoma elasticum • Tuberous sclerosis See **Screening for Vascular related genetic connective tissue Disorders (PVD-2.2)**	• CTA Head (CPT® 70496) **OR** • MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546)
New or worsening clinical symptoms or signs of cerebral aneurysm, including: • Thunderclap headache (see **Sudden Onset of Headache (HD-11.3)**) • Third nerve palsy with pupillary involvement (pupil-sparing third nerve palsies are not caused by external compression) • Suspicion of aneurysm bleed [CT head or MRI brain or CSF exam showing evidence of SAH or intracerebral hemorrhage] • Abnormal CT Head or MRI Brain suggesting possible aneurysm	• CTA Head (CPT® 70496) **OR** • MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **AND/OR** • MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553)
Questionable or equivocal findings on an initial MRA Head	CTA Head (CPT® 70496)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Disorders and Indications (Any of the following)	Medically Necessary Imaging
For suspected or confirmed cerebral aneurysm, ruptured or unruptured, for initial evaluation, treatment, intervention, or follow-up **OR** If initial catheter angiography is negative, repeat imaging is medically necessary.	3D Rendering (CPT® 76377 or CPT® 76376) with cervicocerebral angiography/arteriography and/ or cerebral angiography (See **General Guidelines - Other Imaging Situations (HD-1.7)**)
Follow-up of known cerebral aneurysm: The optimal interval and duration for radiologic follow-up has not been determined. Radiographic follow-up for unruptured or treated intracranial aneurysms upon request by the neurosurgeon or team managing the intracranial aneurysm.	• CTA Head (CPT® 70496) **OR** • MRA Head (CPT® 70544, CPT® 70545 or CPT® 70546) **AND/OR** • MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553)
Additional physical characteristics of a known aneurysm: • To evaluate and treat a giant aneurysm (>2.5 cm) • Posterior fossa aneurysms • Thrombosed or partially thrombosed aneurysms • To evaluate the relationship of the aneurysm to the dura • To evaluate for the presence of calcification • Other surveillance criteria as per the neurosurgeon or team managing the aneurysm repair	• MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553)
Follow up of cerebral aneurysm located in the vertebro-basilar circulation OR If intracranial etiology of SAH has not been found	• MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) **OR** • CTA Neck (CPT® 70498) ◦ CTA Head and Neck (CPT® 70471) must be substituted if performed during the same session

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Disorders and Indications (Any of the following)	Medically Necessary Imaging
Subacute complications (i.e., vasospasm, delayed cerebral ischemia, and hydrocephalus), beginning days to weeks, arising from a subarachnoid hemorrhage and/or aneurysm treatment, upon request from the neurosurgeon and/or team managing the episode	CT Head **OR** MRI Brain contrast as requested
To evaluate individuals with SAH and negative studies for brain aneurysm in whom spinal abnormalities (i.e., AVM) may be suspected as the cause of hemorrhage	MRI Spine (Cervical without and with contrast CPT® 72156, **AND/OR** Thoracic without and with contrast CPT® 72157, **AND/OR** Lumbar without and with contrast CPT® 72158)
Catheter angiogram negative in SAH individual with remaining suspicion for cerebral aneurysm and these studies have not yet been performed:	• CTA Head (CPT® 70496) **AND/OR** • MRA Head (CPT® 70544, CPT® 70545 or CPT® 70546)

- High-risk scenarios for vascular dissection include, but are not limited to: Fibromuscular dysplasia (FMD), Marfan Disease, MVA with whiplash, and chiropractic manipulation
  - MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) or CTA Neck (CPT® 70498) if arterial dissection is suspected, or known and re-evaluation is needed (as directed by neurologist or neurosurgeon or any provider in consultation with a neurologist or neurosurgeon)
  - MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) or CTA Head (CPT® 70496, CPT® 70498) if arterial dissection is suspected, or known and re-evaluation is needed (as directed by neurologist or neurosurgeon or any provider in consultation with a neurologist or neurosurgeon)
  - CTA Head and Neck (CPT ® 70471) combination code must be substituted when both CTA Head (CPT® 70496) and CTA Neck (CPT® 70498) are performed in the same session.
- Other vascular imaging indications for headaches require additional information. See **Stroke/TIA (HD-21.1)**,**Sudden Onset of Headache (HD-11.3)**, **New Headache Onset Older than Age 50 (HD-11.7)**, **Abnormal Blood Clotting (HD-11.9)**, **Pregnancy (HD-11.10)**, **Physical Exertion (HD-11.11)**, and **Systematic Infections (HD-11.13)**

Arteriovenous Malformations (AVMs) and Related Lesions (HD-12.2)

HD.AN.0012.2.A
v2.0.2026

Disorders and Indications (Any of the following)	Medically Necessary Imaging
Any aneurysmal and/or AVM disorders listed in this guideline • When MRI contraindicated • Any urgent setting	• CT Head without contrast (CPT® 70450) **AND/OR** • CTA Head (CPT® 70496) **AND/OR** • CTA Neck (CPT® 70498) ◦ CTA Head and Neck (CPT® 70471) must be substituted if performed during the same session
Known AVM • When requested by a neurologist, neurosurgeon, or any provider in consultation with a neurologist or neurosurgeon	• MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553) **AND/OR** • MRA Head (CPT® 70544, CPT®70545, CPT® 70546) **OR** • CTA Head (CPT® 70496)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Disorders and Indications (Any of the following)	Medically Necessary Imaging
Known AVM in the vertebral-basilar system • When requested by a neurologist, neurosurgeon, or any provider in consultation with a neurologist or neurosurgeon	• Imaging as listed above in "known AVM" **AND/OR** • MRA Neck (CPT® 70547, CPT® 70548, OR CPT® 70549) **OR** • CTA Neck (CPT® 70498) **OR** • CTA Head and Neck (CPT® 70471) must be substituted if performed during the same session
Subarachnoid Hemorrhage (SAH) • AVM is suspected based on a history of SAH	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551)
Hereditary Hemorrhagic Telangiectasia (HHT; Osler-Weber-Rendu Syndrome) • Suspected based on family history with at least one affected first-degree relative (biological parent or sibling) • At diagnosis, especially if confirmed by genetic testing • Screening for confirmed HHT • Clinical signs or symptoms concerning for disease progression • When requested by a neurologist, neurosurgeon, geneticist, or any provider in consultation with a neurologist, neurosurgeon, or geneticist	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551) **AND/OR** • MRA Head (CPT® 70544, CPT® 70545, CPT® 70546) **OR** • CTA Head (CPT® 70496)

- MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551), **OR** CT Head without contrast (CPT® 70450) **AND/OR** MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) or CTA Head (CPT® 70496) is medically necessary for symptoms including headache, seizure, and/or focal neurologic deficits
- For concerns related to stroke, see **Stroke/TIA HD-21.1**
- 3D imaging (CPT® 76376 or CPT® 76377) with MRI Brain without and with contrast (CPT® 70553) OR MRI Brain without contrast (CPT® 70551) is medically necessary.
- 3D Rendering (CPT® 76377 or CPT® 76376) with cervicocerebral catheter angiography is medically necessary to define the presence, location, and anatomy of intracranial and cervical vascular malformations at diagnosis and for follow up, including post-treatment, (see **General Guidelines - Other Imaging Situations (HD-1.7)** and **Background and Supporting Information**).
- See **General Guidelines – CT and MR Angiography (CTA/CTV and MRA/MRV) (HD-1.5)**
- Functional MRI (CPT® 70554 OR CPT® 70555) for surgical planning, see **Functional MRI (fMRI) (HD-24.2)**

Background and Supporting Information

- Trauma is the most common reason for subarachnoid hemorrhage. Ruptured berry aneurysm is the most common reason for non-traumatic subarachnoid hemorrhage in adults.
- Small aneurysms are present in about 1% to 2% of adults, but very few ever reach a size for which bleeding is a risk (>5 mm). Small (<3 mm to 4 mm) unruptured aneurysms in those with no personal history of SAH have a 0.1% to 0.5% a year rate of bleeding. The risk of cerebral aneurysm with family history ranges from 2% with one first-degree relative to 30% to 35% for identical twin or two parents. The risks and benefits of screening these populations need to be considered before advanced imaging.
- AVMs most often come to clinical notice either by bleeding or by acting as a seizure focus. They are usually congenital, recognized later in life and have an initial risk of bleeding of 2% per year.
- Cerebral angiography is a form of angiography which provides images of blood vessels in and around the brain and/or neck. This is a catheter-based procedure, using x-ray imaging guidance and iodine-based contrast to visualize blood vessels.
- Most intracranial AVMs are congenital, vary widely in their location and type, and are discovered at birth due to associated clinical findings or incidentally later in life. Certain hereditary conditions are associated with an increased risk for AVM development.
- Vascular malformations include arteriovenous, venous, cavernous, and capillary malformations.
- Hereditary AVMs usually have an autosomal dominant pattern of inheritance.

Evidence Discussion (HD-12)

v2.0.2026

- After the initial identification of a subarachnoid hemorrhage, the search for a ruptured cerebral aneurysm begins with imaging of the cerebral vessels with CT Angiography (CTA), MR Angiography (MRA) or diagnostic cervicocerebral catheter angiography.[22]
- CTA Head has over 90% sensitivity and specificity for the diagnosis of cerebral aneurysm in the setting of subarachnoid hemorrhage.[22]
- MRA Head has a sensitivity of 95% and a specificity of 89% for diagnosis of cerebral aneurysm.[22]
- Diagnostic cervicocerebral catheter angiography has the highest spatial and temporal resolution of any vascular imaging study, however, is invasive and requires use of contrast. It has a sensitivity and specificity over 98% for identification of aneurysm and can also diagnose vascular abnormalities in up to 13% with subarachnoid hemorrhage and a negative CTA. In addition, this modality can identify an aneurysm in 25% of previously negative studies and repeat studies are supported for this reason.[22]
- In select cases of subarachnoid hemorrhage when an intracranial aneurysm is not identified, imaging the neck vessels and spinal vessels is appropriate.[12]
- Aneurysm growth ranges from 4% to 14% on follow up imaging. For surveillance of incidentally identified cerebral aneurysms or ruptured and/or treated aneurysms, the less invasive modalities, CTA and/or MRA are supported, over the more invasive diagnostic cervicocerebral angiography.[22]
- Screening for cerebral aneurysms in high-risk individual populations is also recommended with the less invasive modalities, CTA head or MRA head. This includes individuals with autosomal dominant polycystic kidney disease (ADPKD), who had a prevalence of cerebral aneurysm ranging from 10%-11.5%. The American Heart Association recommended screening those with at least 2 family members with cerebral aneurysm or subarachnoid hemorrhage.[22]
- Screening is also recommended for conditions with known increased risk of cerebral aneurysm.[4,22]
- Although vascular imaging is the primary focus of neuroimaging in the diagnosis and follow up of cerebral aneurysms, parenchymal imaging with MRI Brain may be helpful in select clinical scenarios including giant aneurysms, posterior fossa aneurysms, in the setting of cranial neuropathies or focal neurologic findings and suspected stroke.[12]
- Cervicocerebral angiography is the gold standard for imaging arteriovenous malformations (AVM) and arteriovenous fistulas (AVF). CT Angiography head (CTA) has a 90% sensitivity for the overall detection of AVMs and 100% for AVMs >3 cm in size. In the evaluation of pulsatile tinnitus, CTA has a sensitivity of 86% with a

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

specificity of 100% in identifying high flow AVFs. MR Angiography (MRA) is an alternative modality in these scenarios.[22]

- MRI Brain for diagnosis and follow up of AVM has an overall sensitivity of 89% and 100% for lesions >3 cm in size.[22]

Head Trauma (HD-13.1)

HD.TR.0013.1.A
v2.0.2026

For acute head trauma (0 to 7 days post-trauma)

- CT Head without contrast (CPT® 70450) is medically necessary in individuals with **ANY** of the following modified Canadian CT Head Rule/New Orleans Criteria.
  - Regardless of documented or stated head impact, ANY "dangerous mechanism of injury", either direct or indirect, including, but not exclusive to:
    - Fall from height greater than 3 feet
    - Fall greater than 5 steps down stairs
    - Any pedestrian motor vehicle accident
    - High impact motor vehicle accident
  - Individual >60 years old
  - Loss of consciousness, amnesia, or disorientation accompanying blunt head trauma within 24 hours
  - Taking one anticoagulant or two antiaggregants, (e.g., aspirin and Plavix)
  - Known platelet or clotting disorder
  - Glasgow coma scale (GCS) score of less than 15 at 2 hours following injury
  - >30 minutes of amnesia before impact
  - Suspected open skull fracture
  - Signs of basilar skull fracture (Battle's sign, Raccoon eyes, CSF rhinorrhea, cranial nerve palsy, hemotympanum, acute hearing loss)
  - Vomiting
  - Alcohol or drug intoxication
  - Visible trauma above clavicles
  - Deficits in short term memory, altered level of alertness, abnormal behavior, or focal neurological deficit
  - Seizure
  - Headache, see **Headache Associated with Head Trauma (HD-11.12))**

For subacute head trauma (7 days to 3 months post-trauma) and chronic head trauma (greater than 3 months post-trauma) symptoms

- MRI Brain without contrast (CPT® 70551) or CT Head without contrast (CPT® 70450) is medically necessary for the initial imaging of individuals with subacute or chronic head trauma and unexplained cognitive or neurologic deficits.
- MRI Brain without and with contrast (CPT® 70553) is medically necessary if post-traumatic infection is suspected.

Repeat and follow-up imaging

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Follow-up imaging is medically necessary for known subdural hematomas, intracerebral hemorrhage, or contusions can be done at the discretion of the ordering provider with one of the following:
  - MRI Brain without and with contrast (CPT® 70553) **OR**
  - MRI Brain without contrast (CPT® 70551) **OR**
  - CT Head without and with contrast (CPT® 70470) **OR**
  - CT Head without contrast (CPT® 70450)
- For short term follow-up imaging of acute traumatic brain injury (TBI) without neurologic deterioration, CT Head without contrast (CPT® 70450) is medically necessary in individuals with ANY of the following risk factors:
  - subfrontal/temporal intraparenchymal contusions
  - anticoagulation
  - age >65 years
  - intracranial hemorrhage
- MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) is medically necessary as a complementary study when neurological findings or symptoms are not sufficiently explained by CT or in subacute and chronic TBI for new, persistent, or slowly progressive symptoms.

For suspected intracranial venous or arterial injury, the following is medically necessary:

- CTA/CTV Head (CPT® 70496) or MRA/MRV Head (CPT® 70544, CPT® 70545, or CPT® 70546)
  - CT and MR Venography (CTV and MRV) are reported with the same codes as the CTA/MRA counterpart. If arterial and venous CT or MR studies are both performed in the same session, only one CPT® code should be used to report both procedures (see **General Guidelines - CT and MR Angiography (CTA/CTV and MRA/MRV) (HD-1.5))**

SPECT, PET, CT/MRI perfusion, DTI (diffusion tensor imaging), functional MRI, and MR spectroscopy are considered not medically necessary for the evaluation of traumatic brain injury.

Quantitative Magnetic Resonance Image (MRI) Analysis of the Brain

- Volumetric or quantitative analysis of the brain or temporal lobes and hippocampus may be requested as (CPT® 0865T or CPT® 0866T)
  - These studies lack sufficient specificity and sensitivity to be clinically useful. Their use is limited to research studies and are considered not medically necessary in the evaluation of traumatic brain injury.

See **Neck (Cervical Spine) Pain Without/With Neurological Features (Including Stenosis) and Trauma (SP-3.2)** in the Spine Imaging Guidelines

See **General Guidelines – CT and MR Angiography (CTA/CTV and MRA/MRV) (HD-1.5)** for traumatic vascular injuries

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Background and Supporting Information

Individuals with head trauma are at risk for facial and cervical trauma.

Recent studies have shown that diffusion tensor MRI tractography may be more sensitive in demonstrating abnormalities such as axonal injury in closed head injury than conventional MRI, but these techniques are best described presently as research tools and their use in clinical practice is not determined.

Decisions regarding return to normal activities, including sports, are made based on the clinical status of the individual and repeat imaging is medically unnecessary.

In cases of post-traumatic infection, contrast-enhanced MRI or CT may be helpful.

Click Here to Return to the Main TOC

Facial Trauma (HD-13.2)

HD.TR.0013.2.A
v2.0.2026

- CT Maxillofacial without contrast (CPT® 70486) and/or CT Head without contrast (CPT® 70450) is/are medically necessary for any concern regarding significant injury to facial structures including, but not limited to:
  - Concern for orbital, maxillary, or mandibular fractures
  - Trauma with associated symptoms of anosmia, hearing, vision or speech changes, vertigo, facial numbness
  - Physical exam findings of CSF rhinorrhea (suspected post-traumatic CSF leak), malocclusion, severe focal facial tenderness, focal loss of facial sensation
- CT Orbits/Temporal Bone without contrast (CPT® 70480) and/or CT Head without contrast (CPT® 70450) is/are medically necessary for:
  - concern for orbital injury or orbital wall fracture
  - symptoms of diplopia, blurred vision, vision loss
  - physical exam findings of enophthalmos, entrapment of extraocular muscle(s)
  - suspicion for temporal bone fracture
  - physical exam findings of CSF otorrhea (suspected post-traumatic CSF leak)
- MRI Maxillofacial without contrast (CPT® 70540) **OR** MRI Maxillofacial without and with contrast (CPT® 70543) is medically necessary for evaluation of cranial nerve deficits not explained or incompletely characterized on CT.
- If concern for CSF leak and CT Maxillofacial or Temporal bone is inconclusive, (see **Low-Pressure Headache and CSF Leak (HD-11.15)**)

Background and Supporting Information

Imaging is not necessary in the evaluation of simple nasal fractures if tenderness and swelling is limited to the nasal bridge, the individual can breathe through each naris, and there is no septal hematoma.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Evidence Discussion (HD-13)

v2.0.2026

- For evaluation of acute mild head trauma, less than 10% will have positive findings on CT head, and of this group, less than 1% will require neurosurgical intervention.[7,18]
- The American College of Emergency Physicians and the Choosing Wisely Initiative recommend avoiding CT scans of the head in emergency department individuals with minor head injury who are at low risk based on validated decision rules. This recommendation was based on the concern for individual exposure to ionizing radiation and the increased lifetime risk of cancer with such exposure.[17]
- Selective CT scanning is recommended by validated clinical practice guidelines, including the New Orleans Criteria and the Canadian CT Head Rule.[1,7,18] Both guidelines are 100% sensitive for mild head trauma requiring neurosurgical intervention.[7,18] The New Orleans Criteria has a sensitivity >97% for any traumatic finding on CT, with a specificity less than 6%.[7,18] The Canadian CT Head Rule has a sensitivity between 83.4% - 87.2% with a specificity between 37.2% – 39.7%.[1,7,18] The Canadian CT Head Rule has a 100% sensitivity and 29% specificity in cases of intracranial hemorrhage.[1,7,18]
- When imaging is indicating by a validated clinical decision rule, CT head is the preferred imaging modality for evaluation of acute head trauma.[7,15,17,18]
- If the initial CT head confirms subdural hematoma, follow-up CT head is supported to monitor progression.[7,8]
- For follow-up in individuals with persistent neurologic deficits without etiology identified on initial CT head, MRI brain is more sensitive, and can visualize cortical contusions, subdural hematomas, and white matter lesions in diffuse axonal injury.[7] Up to 27% of individuals with mild traumatic brain injury (TBI) with normal initial CT head show abnormalities on MRI Brain.[7,8]
- When vascular injury is suspected in the setting of head trauma, CT Angiography (CTA) head and neck is a non-invasive, rapid, and useful modality to evaluate for arterial injury.7,1 MR Angiography is an alternative option. For suspected intracranial venous injury, CT Venography (CTV) is medically necessary, with MR Venography (MRV) an alternative option.[7,16]
- There is insufficient evidence to support the use of single-photon emission computed tomography (SPECT), FDG-PET/CT brain, CT/MRI-Perfusion, MR spectroscopy (MRS), functional MRI (fMRI), or diffusion tensor imaging (DTI) in the evaluation of head trauma.[7]
- Individuals with head trauma are also at risk for orbital, facial and temporal bone injuries.[11] CT of the orbit can diagnose fractures, displaced fracture fragments, foreign bodies, traumatic hematoma, and extraocular muscle injury.[11] CT head is also recommended in the evaluation of suspected orbital fractures due to concomitant intracranial injury incidence of 9%.[16]

Click Here to Return to the Main TOC

- CT maxillofacial is useful in diagnosing maxillofacial injuries including non-displaced fractures. CT provides multiplanar and 3-D image reconstructions, allowing for better characterization of complex fractures, which is useful for surgical planning.[16]
- Over one-third of individuals with frontal sinus fractures are likely to have a concomitant intracranial injury, thus concurrent CT head imaging is recommended in individuals with suspected frontal sinus fractures. In addition, between 8% to 10% of individuals with frontal sinus fractures have subdural or epidural hematomas requiring surgical treatment.[16]
- High resolution CT (HRCT) facial and temporal bone are sensitive modalities for subtle or non-displaced skull base defects, with sensitivity of 92% for identifying cerebrospinal fluid leak.[7,15]

CNS and Head Infection (HD-14.1)

HD.HI.0014.1.A
v2.0.2026

INITIAL IMAGING

- Signs of intracranial infection include, but are not limited to:
  - headaches, seizures, meningeal signs (neck stiffness)
  - new focal neurological deficits in a setting of fever or elevated white blood cell count (WBC)
  - known infection elsewhere **or**
  - immunosuppression
- **ONE** of the following studies is medically necessary for suspected intracranial infection if any of these signs of infection are present:
  - MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551) **OR**
  - CT Head (CPT® 70450, CPT® 70460, or CPT® 70470) in cases where MRI is contraindicated, in urgent scenarios, or prior to lumbar puncture, see **General Guidelines-CT Head (HD-1.4)**
  - If vascular involvement is suspected, in addition to MRI Brain, the following are medically necessary:
    - MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **OR**
    - CTA Head (CPT® 70496) **AND/OR**
    - MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) **OR**
    - CTA Neck (CPT® 70498) **OR**
    - CTA Head and Neck (CPT® 70471) must be substituted if performed during the same session
    - (CT and MR Venography (CTV and MRV) are reported with the same codes as the CTA/MRA counterpart (there is no specific code for CT/MR venography)
  - Concern for vasculitis, see **Cerebral Vasculitis (HD-22)**

REPEAT IMAGING

- As requested by an infectious disease specialist, neurologist, neurosurgeon, radiologist, or any provider coordinating care with an infectious disease specialist, neurologist, neurosurgeon, or radiologist
- Repeat imaging would refer to any of the CPT codes listed above as initial imaging.
  - See **General Guidelines – CT Head (HD-1.4)** regarding additional indications for CT Head.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- See **Skull Base Osteomyelitis (SBO) (HD-20.1)**, **Sinus and Facial Imaging (HD-29.1)**, **Dental/Periodontal/Maxillofacial Imaging (HD-30.2)**, **Mental Status Change (HD-4.2)**, and **Eye Disorders and Visual Loss (HD-32.1)**

Evidence Discussion (HD-14.1)

- A head CT is recommended for quickly assessing intracranial infections in urgent cases. However, MRI is more effective for examining conditions that affect the cranial nerves, brain tissue, and meninges.[15] Although MRI is superior in detecting minor changes in the brain associated with infections, CT scans can promptly identify pathophysiological changes that may influence the individual's prognosis.[1]
- Acute bacterial meningitis often presents with a normal CT scan. However, due to the high mortality rate of up to 50% when left untreated, a CT scan is necessary to rule out other causes of encephalopathy or neurologic deficits. In certain clinical situations, CT is also required to exclude increased intracranial pressure before performing a lumbar puncture. Venous thromboses increase the risk of hemorrhage and are linked to high mortality. Consequently, both CT and MRI scans, including T1-weighted sequences, are recommended. These scans help detect high signal changes in several venous sinuses and can be complemented with CT or MRvenography.
- Similar considerations apply when diagnosing non-bacterial central nervous system (CNS) infections. CT scans are advantageous due to quick access to care, faster diagnosis, and earlier treatment initiation, which can reduce morbidity. However, MRI is superior in detecting patterns of vasogenic versus cytotoxic edema, contrast enhancement, and the distribution of involvement, whether multifocal or unifocal/unihemispheric. These distinctions are crucial in differentiating between differential diagnoses, such as systemic infections with hematogenous spread versus head/neck infections with a direct spread pattern.[39]
- Many individuals present with neurologic signs and symptoms that are indicative of either a cortical or subcortical syndrome. Often, these cannot be fully characterized by clinical presentation alone. As a result, radiologic evaluation becomes essential in diagnosing the etiology of the underlying process. The potential causes are varied and include meningoencephalitis, acute cerebrovascular disease, hemorrhagic necrotizing encephalopathy, immune-mediated (Bickerstaff) encephalitis, and demyelinating diseases such as acute disseminated encephalomyelitis (ADEM) and multiple sclerosis (MS).[40] Therefore, prompt and accurate diagnosis is critical to select the most appropriate imaging method (MRI vs. CT) for each clinical scenario.

Neuro-COVID-19 and Sars-CoV-2 Vaccines (HD-14.2)

HD.HI.0014.2.A
v2.0.2026

- The following studies are medically necessary for evaluation of:
  - Acute or chronic Neuro-COVID-19 syndrome
    - MRI Brain without contrast (CPT® 70551) **OR**
    - MRI Brain without and with contrast (CPT® 70553) **OR**
    - CT Head without contrast (CPT® 70450) **OR**
    - CT Head without and with contrast (CPT® 70470) is medically necessary if there is a contraindication to MRI **AND/OR**
    - MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) OR CTA Head (CPT® 70496) **AND/OR**
    - MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) or CTA Neck (CPT® 70498)
      - CTA Head and Neck (CPT® 70471) must be substituted if performed during the same session
    - CT and MR Venography (CTV and MRV) are reported with the same codes as the CTA/MRA counterpart (there is no specific code for CT/MR venography):
      - If arterial and venous CT or MR studies are both performed in the same session, only one CPT® code is used to report both procedures
      - If an arterial CTA or MRA study has been performed and subsequently a repeat study is needed to evaluate the venous anatomy, then this study is medically necessary
      - If a venous CTV or MRV has been performed and subsequently a repeat study is needed to evaluate the arterial anatomy, then this study is medically necessary
      - MRA without and with contrast with venous sinus thrombosis to differentiate total from subtotal occlusion is medically necessary
  - For suspected neurologic adverse reactions after SARS- CoV-2 vaccination, the following is medically necessary:
    - MRI Brain without contrast (CPT® 70551) **OR**
    - MRI Brain without and with contrast (CPT® 70553) **OR**
    - CT Head without contrast (CPT® 70450) **OR**
    - CT Head without and with contrast (CPT® 70470) is medically necessary if there is a contraindication to MRI **AND/OR**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) OR CTA Head (CPT® 70496) **AND/OR**
- MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) or CTA Neck (CPT® 70498)
  - CTA Head and Neck (CPT® 70471) must be substituted if performed during the same session
- CT and MR Venography (CTV and MRV) are reported with the same codes as the CTA/MRA counterpart (there is no specific code for CT/MR venography):
  - If arterial and venous CT or MR studies are both performed in the same session, only one CPT® code is used to report both procedures
  - If an arterial CTA or MRA study has been performed and subsequently a repeat study is needed to evaluate the venous anatomy, then this study is medically necessary
  - If a venous CTV or MRV has been performed and subsequently a repeat study is needed to evaluate the arterial anatomy, then this study is medically necessary
  - MRA without and with contrast with venous sinus thrombosis to differentiate total from subtotal occlusion is medically necessary

◦ If suspected transverse myelitis, acute necrotizing myelitis, and/or COVID-19 infection, then **ANY** the following are medically necessary:
- MRI Cervical without and with contrast (CPT® 72156)
- MRI Thoracic without and with contrast (CPT® 72157)
- MRI Lumbar Spine without and with contrast (CPT® 72158)
- See **Stroke/TIA (HD-21.1)** for vascular imaging
- See **Transverse Myelitis (HD-16.4)** regarding spine imaging to evaluate for post-vaccination neurological syndrome

• Repeat imaging considered on a case-by-case basis for a change in neurological symptoms or signs on the neurological exam and/or change in the treatment.

Background and Supporting Information

• The findings observed in the central nervous system in the acute-phase of COVID- 19 may extend into a prolonged symptomatic phase of Neuro-COVID in long haulers with chronic COVID syndrome. Symptoms may include, but are not inclusive to: "brain fog", dizziness, inability to concentrate, psychiatric symptoms, and confusion.

• Acute-phase neurologic manifestations of COVID-19 include: headache, dizziness, taste and smell dysfunction, impaired consciousness (described as confusion or agitation), cerebrovascular events (ischemic stroke, cerebral venous sinus thrombosis, cerebral hemorrhage), seizures, meningoencephalitis, and immune-mediated neurologic diseases (Guillan-Barre syndrome, Miller-Fisher syndrome, polyneuritis cranialis, transverse myelitis).

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Neurologic adverse reactions in those receiving SARS-CoV-2 vaccines, including mRNA vaccines (Pfizer, Moderna), have been reported, and include, although not limited to: headache, Guillan-Barre syndrome, transverse myelitis, facial nerve palsy, small fiber neuropathy, autoimmune encephalitis, reversible cerebral vasoconstriction syndrome, multiple sclerosis, neuromyelitis optica, intracerebral bleeding, cerebral venous sinus thrombosis, hypophysitis, epilepsy, encephalopathy, and acute disseminated encephalomyelitis.
- Cases of Thrombosis with Thrombocytopenia Syndrome (TTS) following administration of the Johnson & Johnson/Janssen COVID-19 Vaccine have been reported in males and females, in a wide age range of individuals 18 years and older, with the highest reporting rate (approximately 8 cases per 1,000,000 doses administered) in females ages 30-49 years; overall, approximately 15% of TTS cases have been fatal. Currently available evidence supports a causal relationship between TTS and the Johnson & Johnson/Janssen COVID-19 Vaccine. The clinical course of these events shares features with autoimmune heparin-induced thrombocytopenia. In individuals with suspected TTS following administration of the Johnson & Johnson/ Janssen COVID-19 Vaccine, the use of heparin may be harmful and alternative treatments may be needed. Consultation with hematology specialists is strongly recommended. The American Society of Hematology has published considerations relevant to the diagnosis and treatment of TTS following administration of the Janssen COVID-19 Vaccine.

Evidence Discussion (HD-14.2)

- A head CT is recommended for quickly assessing intracranial infections in urgent cases. However, MRI is more effective for examining conditions that affect the cranial nerves, brain tissue, and meninges.[15] Although MRI is superior in detecting minor changes in the brain associated with infections, CT scans can promptly identify pathophysiological changes that may influence the individual's prognosis.[1]
- Acute bacterial meningitis often presents with a normal CT scan. However, due to the high mortality rate of up to 50% when left untreated, a CT scan is necessary to rule out other causes of encephalopathy or neurologic deficits. In certain clinical situations, CT is also required to exclude increased intracranial pressure before performing a lumbar puncture. Venous thromboses increase the risk of hemorrhage and are linked to high mortality. Consequently, both CT and MRI scans, including T1-weighted sequences, are recommended. These scans help detect high signal changes in several venous sinuses and can be complemented with CT- or MR-venography.
- Similar considerations apply when diagnosing non-bacterial central nervous system (CNS) infections. CT scans are advantageous due to quick access to care, faster diagnosis, and earlier treatment initiation, which can reduce morbidity. However, MRI is superior in detecting patterns of vasogenic versus cytotoxic edema, contrast enhancement, and the distribution of involvement, whether multifocal or unifocal/

Autoimmune/Paraneoplastic Encephalitis & Neuroinflammatory Disorders (HD-14.3)

HD.HI.0014.3.A
v2.0.2026

Indications:

When acute/subacute or rapid progression (<3 months) of altered mental status, focal findings including cranial nerve, motor or sensory symptoms or memory loss or psychiatric symptoms, seizure, and/or focal CNS findings are present.

OR

There is a stated concern for neuro-inflammatory encephalitis from or in consultation with a neurologist, neurosurgeon, psychiatrist, oncologist, rheumatologist, or infectious disease specialist.

Medically Necessary Initial Imaging:

- MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551) **OR**
- CT Head without contrast (CPT® 70450) **OR** CT Head without and with contrast (CPT® 70470) when MRI is unavailable or contraindicated or for bony pathology concerns
- MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **OR** CTA Head (CPT® 70496) **AND/OR** MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) **OR** CTA Neck (CPT® 70498)
  - CTA Head and Neck (CPT ® 70471) must be submitted if performed during the same session

  The above imaging studies are for evaluating large vessel obstructions, aneurysms and vascular malformations, dissection, vasospasm, and vasculopathies such as CNS vasculitis (see **Cerebral Vasculitis (HD-22.1)**, **Cerebral Aneurysms (HD-12.1)**, **Arteriovenous Malformations (AVMs) and Related Lesions (HD-12.2)**, **Stroke/TIA (HD-21.1)**)

Medically Necessary Repeat Imaging:

MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551) when specialized sequences are needed such as, but not limited to:

- high T2 contrast sequences (CISS, FIESTA) sequences to identify blood (SWI) or

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- identifying acute cytotoxic edema (DWI) or
- when requested by or in consultation with a neurologist, oncologist, rheumatologist, infectious disease specialist, neurosurgeon, or psychiatrist

Metabolic (FDG) Brain PET (CPT® 78608) is medically necessary to evaluate individuals suspected of having encephalitis, including autoimmune encephalitis, if diagnosis remains unclear after evaluation with MRI Brain, CSF analysis, and/or lab testing including serology.

Neurosarcoidosis:

- The following are medically necessary for known or suspected neurosarcoidosis.
  - MRI Brain without and with contrast (CPT® 70553)

    AND/OR
  - If spinal cord involvement suspected, then
    - MRI Cervical Spine without and with contrast (CPT® 72156) **AND/OR**
    - MRI Thoracic Spine without and with contrast (CPT® 72157) **AND/OR**
    - MRI Lumbar Spine without and with contrast (CPT® 72158)

    AND/OR
  - If peri-orbital involvement suspected, then
    - MRI Orbits/Face/Neck without and with contrast (CPT® 70543)
  - Repeat imaging supported if requested by neurologist, rheumatologist, ophthalmologist, oncologist, or radiologist or provider in consultation with a neurologist, rheumatologist, ophthalmologist, oncologist or radiologist.
- For non-neurologic imaging related to sarcoidosis (see **Sarcoid (CH-15.1)**)

Background and Supporting Information

Supportive studies in the evaluation of Autoimmune/Paraneoplastic Encephalopathy include:

- CSF pleocytosis (>5 WBC/µL) or
- EEG changes or
- Supporting labs (including positive CSF antibody positivity and/or serologies)

Potential etiologies:

- Paraneoplastic
  - NMDA Receptor encephalitis
  - LGI1 antibody encephalitis
- Autoimmune
  - Neurosarcoidosis can involve any of the following:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

    - Brain, Cranial Nerves, Spinal Cord, and/or Peripheral Nerves
    - Acute Disseminated Encephalomyelitis (ADEM), Anti-MOG Syndrome, Multiple Sclerosis (MS), Neuromyelitis Optica (NMO)
    - IgG4 related disease
    - CNS histiocytosis
- Neuro-rheumatologic
  - ANCA related disease
  - Behcet's disease
  - Sjogren Syndrome +/- Rheumatoid Arthritis (RA)

FDG-PET imaging of the brain for paraneoplastic and autoimmune encephalitis may be more sensitive than brain MRI (87% vs. 56%) but is nonspecific. Areas of hypometabolism are seen in neurodegenerative disorders such as dementias. However, topographic patterns of hypometabolism may help characterize the disorder as autoimmune/ paraneoplastic encephalitis, in a way that may help clarify diagnosis and alter management strategies. For example, anterior to posterior gradient of hypometabolism is seen in NMDA Receptor encephalitis. Hemispheric hypometabolism out of proportion to atrophy characterizes Rasmussen encephalitis.

Non-Head Imaging

- MRI is helpful in determining the length of spine lesion (short versus longitudinally extensive transverse myelitis), width (partial versus transverse), and location (eccentric, central, hemicord, anterior versus posterior, conus, tracts, or meningeal).
  - See **Myelopathy (SP-7.1)** and **Anti-MOG Syndromes (HD-16.3)**
- The Trident Sign on axial MRI, which has been described in relation to neurosarcoidosis, demonstrates leptomeningeal or dorsal subpial enhancement that may or may not involve the central canal.
  - See **Myelopathy (SP-7.1)**
- Involvement of the conus medullaris is a clue to Anti-MOG (Myelin Oligodendrocyte Glycoprotein-associated disorder) as the cause of longitudinally extensive transverse myelitis.
  - See **Transverse Myelitis (HD-16.4)**
- CT of the chest, abdomen, and pelvis with contrast is a generally accepted first method of screening for occult malignancy or systemic inflammation (e.g., sarcoidosis).
  - See **Paraneoplastic Syndromes (ONC-30.3)** and **Sarcoid (CH-15.1)**

Evidence Discussion (HD-14.3)

- The American College of Radiology (ACR) Appropriateness Criteria® provided guidance on the appropriateness of CT versus MRI Brain in certain clinical scenarios

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

relating to altered mental status. For acute, undifferentiated presentations and with focal symptoms, CT Head is an appropriate modality, but with known intracranial process, suspected medical illness or toxic-metabolic etiology, and/or psychosis, MRI Brain, is appropriate and in some cases may be preferable.[45]

- In the appropriate clinical scenarios, recognition of structural and functional imaging patterns of brain involvement using CT head, MRI brain, and brain PET, in autoimmune encephalitis (including paraneoplastic and non-rheumatologic inflammatory disorders) can facilitate rapid access to appropriate treatment, as well as avoid invasive diagnostic procedures such as brain biopsy.[26]
- FDG-PET/CT brain performed at a median 4 weeks of symptom onset was more often abnormal than initial MRI, EEG, or laboratory cerebrospinal fluid testing, in individuals with suspected autoimmune encephalitis (AE), with focal hypometabolism, the most common PET/CT finding.[2]
- Spine MRI shows abnormalities in up to 45% of cases of paraneoplastic myeloneuropathy.[47]
- The three-dimensional (3D) constructive interference in steady state (CISS) is a gradient-echo MRI or Fast Imaging Employing Steady-state Acquisition Cycled Phases (FIESTA-C) on GE MRI systems are widely employed for over a decade and have been shown to have utility in demonstration of contrast between cerebrospinal fluid and brain parenchymal structure. Therefore, these have particular utility in the examination of cranial nerves, the ventricular system, cavernous sinus, and other structures which are commonly involved in neuro-inflammatory conditions.[48]
- Neuropsychiatric lupus and other neuro-inflammatory conditions have been described to mimic vascular disease, such as vasculitis and small vessel cerebrovascular disease, and in these cases vessel imaging with CT Angiography (CTA) and MR Angiography (MRA) Brain can contribute to meaningful diagnosis.[49]
- In the evaluation of a first episode of psychosis when an autoimmune cause is suspected, up to 4% of cases have abnormalities on MRI brain.[50]
- Sarcoidosis can manifest with neurologic complications in every part of the neural axis, with diagnostic challenges represented by multiple pathophysiologic pathways and frequently lack of specific histopathologic diagnosis. In clinically suspected neurosarcoidosis on the basis of synthesized clinical history and physical examination findings, the demonstration of neuro-inflammation using cerebrospinal fluid testing and contrast-enhanced MRI is useful. In difficult or complicated cases, FDG-PET and Gallium-67 imaging have been useful for identification of targets for biopsy.[h1]

Movement Disorders (HD-15.1)

HD.MD.0015.1.A
v2.0.2026

- The majority of movement disorders are diagnosed based on a clinical diagnosis and imaging is not medically necessary. These include:
  - typical Parkinson's Disease
  - essential tremor or tremors of anxiety or weakness
  - restless leg syndrome
  - tics or spasms which can be duplicated at will
  - Tourette syndrome
  - tardive dyskinesia
- MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) is medically necessary in the following clinical scenarios:
  - Clinical diagnostic uncertainty
  - Incomplete or uncertain response to medication
  - Anti-psychotic drug-induced Parkinsonism or atypical tardive dyskinesia
  - Atypical Parkinsonism suspected because of unusual clinical features. These may include, but are not limited to:
    - Persistent unilateral signs or symptoms
    - Onset under age 50
    - Rapid progression
    - See *Background and Supporting Information* for further information on atypical parkinsonism and Parkinson's Plus Syndromes
  - Suspected Huntington Disease
- Evaluation for surgical treatment of essential tremor, Parkinson's disease, and/or spasmodic torticollis/dystonia, see **Torticollis and Dystonia (Neck-10.2)** in the Neck Imaging Guidelines
  - Deep Brain Stimulation (DBS) therapy
    - MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) **AND/OR** unlisted CT procedure code (CPT® 76497) are medically necessary
  - MR guided Focused Ultrasound:
    - CT Head without contrast (CPT® 70450) to evaluate bone density **AND/OR** MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) are medically necessary
  - Repeat imaging studies for pre-surgical evaluation, MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) **AND/OR** CT Head without contrast (CPT® 70450), are medically necessary when ordered by a

Neurosurgeon or Neurologist or any provider in consultation with a Neurosurgeon or Neurologist if greater than 6 months old **and/or** for new symptoms/signs
  - Post-op imaging is medically necessary when ordered by a Neurosurgeon or Neurologist or any provider in consultation with a Neurosurgeon or Neurologist for either procedure, see also **Post-Operative Imaging (HD-28.3)** indications
- Dopamine Transporter Scan [DAT-SPECT Radiopharmaceutical Localization SPECT (Ioflupane I-123 SPECT)] (CPT® 78803 or CPT® 78830) **OR** Fluorodopa F^{18} (F-DOPA) PET Brain (CPT® 78608) is medically necessary to:[2,3,16,17,18]
  - evaluate motor symptoms (tremor, rigidity, bradykinesia, and/or postural instability) in suspected Parkinsonian Syndromes (Parkinson Disease, Multiple System Atrophy, Progressive Supranuclear Palsy, Corticobasal Degeneration) when the diagnosis is unclear, to differentiate from non-neurodegenerative disorders, such as Essential Tremor, drug-induced tremor, vascular parkinsonism, and/or psychogenic tremor
  - Imaging with either modality, **not both**, is medically necessary when the diagnosis remains unclear after evaluation by a neurologist, medication trials and brain imaging.
  - See ***Background and Supporting Information*** for additional information regarding Parkinson's Plus Syndromes.
  - Neither DAT Scans nor F-DOPA PET scans are medically necessary for differentiation of subtypes of Parkinson's syndromes, to monitor progression of disease, or predict risk of development of disease mainly to exclude other conditions with similar clinical presentations.
- MRI Brain without and with contrast (CPT® 70553) is medically necessary for initial imaging for suspected motor neuron disease (see **Motor Neuron Disease/ Amyotrophic Lateral Sclerosis (ALS) (PND-8.1)** in the Peripheral Nerve and Neuromuscular Disorders Imaging Guideline)
- Dementia associated with movement disorder (see **Lewy Body Dementia (LBD) – SPECT Brain Scan and PET (HD-8.3))**

Background and Supporting Information

- Parkinson's Plus Syndromes are a group of disorders characterized by atypical parkinsonism. They are NOT Parkinson's disease. They represent different neurodegenerative diseases with features of PD, and may be confused with PD. These syndromes include, but are not limited to:
  - Multiple system atrophy: orthostatic hypotension (dysautonomia), dysphonia, dysarthria
  - Progressive Supranuclear Palsy: balance difficulties, vertical gaze paresis
  - Corticobasal Syndrome: dysphasia, apraxia, myoclonus, alien-limb phenomenon
- These are distinct entities. Care must be taken to determine if there are unusual features present that will suggest atypical parkinsonian syndrome.

- Dementia with Lewy bodies (DLB): dementia prior to movement disorder (see **Lewy Body Dementia (LBD) - SPECT Brain Scan and PET (HD-8.3)**)

Evidence Discussion (HD-15)

- The majority of movements disorders are diagnosed based on history and clinical examination findings and do not require imaging.[1,2,3,24] For cases of diagnostic uncertainty, incomplete response to medication, for atypical Parkinsonism or drug-induced parkinsonism, and for suspected Huntington disease, MRI brain is the preferred imaging modality.[1,3,24]
- Structural imaging with MRI Brain is usually normal in individuals with Parkinson's disease but is useful to diagnose causes of secondary parkinsonism, such as stroke, iron deposition, normal pressure hydrocephalus, and neoplasm.[1,2,3]
- CT Head is not preferred due to its limited soft-tissue characterization when compared to MRI.[1]
- Functional imaging studies assessing dopaminergic function in Parkinson's disease include single-photon emission computed tomography (SPECT) and positron emission tomography (PET) imaging.1,2,3 These studies are used as an adjunct diagnostic test.[1,2,3]
- Both Dopamine Transporter single-photon emission computed tomography (DAT-SPECT) and [18F]-fluorodopa (F-DOPA) PET brain are useful to differentiate suspected parkinsonian syndromes from non-neurodegenerative disorders such as Essential Tremor, drug-induced tremors, vascular parkinsonism, and/or psychogenic tremors.[1,2,3,17,18]
- DAT-SPECT has a sensitivity of 91% with a specificity of 100% for essential tremor, a sensitivity of 86.2% with a specificity of 93.8% for drug-induced parkinsonism, and a sensitivity of 86.2% with a specificity of 82.9% for vascular parkinsonism.[18,25,26]
- F-DOPA PET brain has a sensitivity of 73% with a specificity of 91% for evaluation of parkinsonian syndrome vs non-neurodegenerative parkinsonian syndrome.[17]
- Neither DAT-SPECT scans nor F-DOPA PET brain scans are useful for the differentiation between subtypes of Parkinsonian syndromes, to monitor progression of disease nor to predict the risk of development of disease.[1,2,3]
- There is insufficient evidence for the routine use of FDG-PET brain in the diagnosis of parkinsonian syndromes.[1]

Multiple Sclerosis (MS) (HD-16.1)

HD.MS.0016.1.A
v2.0.2026

Establishing a New Diagnosis of Multiple Sclerosis

Repeat Imaging for Unclear Diagnosis

New Neurologic Symptoms in an Individual with Multiple Sclerosis

Baseline Imaging with Disease Modifying Therapy (DMT)

Current Treatment with High-Risk Disease Modifying Therapy (DMT)

Annual Imaging on Low-Risk DMT or No Treatment

History of Clinically Isolated Syndrome (CIS) or Radiologically Isolated Syndrome (RIS)

Prolonged Treatment with Tysabri® (natalizumab)

Progressive Multifocal Leukoencephalopathy (PML) Evaluation

Background and Supporting Information

Multiple Sclerosis General Information Page

- MRI Lumbar Spine is not medically necessary since Cervical and Thoracic studies will usually visualize the entire spinal cord. If the clinical concern is for lumbosacral radiculopathy, see **Lower Extremity Pain with Neurological Features (Radiculopathy, Radiculitis, or Plexopathy and Neuropathy) with or without Low Back (Lumbar Spine) Pain (SP-6.1)** in the Spine Imaging Guidelines.
- Family members need not be screened, unless they exhibit suspicious signs or symptoms suggestive of MS.
- Computed Tomography (CT) scans of the head and/or spine are **NOT** medically necessary for the evaluation of multiple sclerosis due to inferior soft tissue resolution when compared to MRI.
- Quantitative Magnetic Resonance Image (MRI) Analysis of the Brain
  - Volumetric or quantitative analysis of the brain or temporal lobes and hippocampus may be ordered as (CPT® 0865T or CPT® 0866T).
    - These studies lack sufficient specificity and sensitivity to be clinically useful. Their use is limited to research studies and are not medically necessary in the evaluation of Multiple Sclerosis.

Proprietary Information of UnitedHealthcare.

Establishing a New Diagnosis of Multiple Sclerosis

Indication	Medically Necessary Imaging
Establishing a new diagnosis of Multiple Sclerosis is based on the following: • Clinical suspicion based on recurrent episodes of variable neurological signs and/or symptoms **AND** • Baseline exclusion of appropriate alternative conditions that can mimic MS **OR** Clinically Isolated Syndrome (CIS)* based on **ALL** the following: • First episode of neurologic symptoms and neurologic deficits concerning for possible demyelinating disease • Symptoms last ≥24 hours • Baseline exclusion of appropriate alternative conditions that can mimic MS **OR** Radiologically Isolated Syndrome (RIS)* based on **ALL** the following: • Individual with brain MRI obtained for unrelated reason with findings conspicuous for demyelinating disease	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551) if there is a contraindication to gadolinium If optic neuritis** is suspected the following imaging is **ALSO** medically necessary: • MRI Orbit without and with contrast (CPT® 70543) **OR** • MRI Orbit without contrast (CPT® 70540) ****For additional information related to optic neuritis see Eye Disorders and Visual Loss (HD-32.1)** **AND/OR** • MRI Cervical Spine without and with contrast (CPT® 72156) **OR** • MRI Cervical Spine without contrast (CPT® 72141) **AND/OR** • MRI Thoracic Spine without and with contrast (CPT® 72157) **OR** • MRI Thoracic Spine without contrast (CPT® 72146)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging
• Baseline exclusion of appropriate alternative conditions that can mimic MS *For more information about CIS and RIS, see ***Background and Supporting Information***	

Repeat Imaging for Unclear Diagnosis

Indication	Medically Necessary Imaging
Diagnosis of Multiple Sclerosis remains unclear or equivocal after initial MRI • Repeat imaging 3-6 months after initial MRI Brain	• MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

New Neurologic Symptoms in an Individual with Multiple Sclerosis

Indication	Medically Necessary Imaging
New neurologic signs or symptoms in an individual with multiple sclerosis	• MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553) If optic neuritis is suspected**, the following imaging is **ALSO** medically necessary: • MRI Orbit without and with contrast (CPT® 70543) **OR** • MRI Orbit without contrast (CPT® 70540) ****For additional information related to optic neuritis, see Eye Disorders and Visual Loss (HD-32.1)** If there are new or worsening symptoms concerning for spinal cord involvement, the following imaging is **ALSO** medically necessary: • MRI Cervical Spine without contrast (CPT® 72141) **OR** • MRI Cervical Spine without and with contrast (CPT® 72156) **AND/OR** • MRI Thoracic Spine without contrast (CPT® 72146) **OR** • MRI Thoracic Spine without and with contrast (CPT® 72157)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Baseline Imaging with Disease Modifying Therapy (DMT)

Indication	Medically Necessary Imaging
• Before starting **OR** changing disease modifying therapy (DMT) **AND/OR** • 3-6 months after starting or changing DMT to establish a new MRI treatment baseline **AND/OR** • If there are new abnormal MRI Brain findings without clinical symptoms, an additional follow-up MRI Brain is supported after 6 months	• MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553)

Current Treatment with High-Risk Disease Modifying Therapy (DMT)

Indication	Medically Necessary Imaging *Every 6 Months*	Medically Necessary Imaging *Annually*
Individuals treated with DMT* associated with either the risk of progressive multifocal leukoencephalopathy (PML) **AND/OR** other CNS opportunistic infections * For list of medications, see ***Background and Supporting Information***	• MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553)	• MRI Cervical Spine without contrast (CPT® 72141) **OR** • MRI Cervical Spine without and with contrast (CPT® 72156) **AND/OR** • MRI Thoracic Spine without contrast (CPT® 72146) **OR** • MRI Thoracic Spine without and with contrast (CPT® 72157)

Proprietary Information of UnitedHealthcare.

Annual Imaging on Low-Risk DMT or No Treatment

Indication	Medically Necessary Imaging Annually
Individuals with diagnosed Multiple Sclerosis with **EITHER** of the following: • Not treated with disease modifying therapy (DMT)* **OR** • Treated with low-risk DMT (beta interferon or glatiramer acetate medications) * For list of DMT medications, see ***Background and Supporting Information***	• MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553) **AND/OR** • MRI Cervical Spine without contrast (CPT® 72141) **OR** • MRI Cervical Spine without and with contrast (CPT® 72156) **AND/OR** • MRI Thoracic Spine without contrast (CPT® 72146) **OR** • MRI Thoracic Spine without and with contrast (CPT® 72157)

Proprietary Information of UnitedHealthcare.

Prolonged Treatment with Tysabri® (natalizumab)

Indication	Medically Necessary Imaging *Every 3-6 Months*	Medically Necessary Imaging *Annually*
Individuals treated with Tysabri® (natalizumab) with the following medical history: • ≥18 months of treatment ◦ During Tysabri® (natalizumab) treatment and up to 9-12 months after transitioning off Tysabri® (natalizumab) **AND** • JC virus antibody positive	• MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553)	• MRI Cervical Spine without contrast (CPT® 72141) **OR** • MRI Cervical Spine without and with contrast (CPT® 72156) **AND/OR** • MRI Thoracic Spine without contrast (CPT® 72146) **OR** • MRI Thoracic Spine without and with contrast (CPT® 72157)

Progressive Multifocal Leukoencephalopathy (PML) Evaluation

Indication	Medically Necessary Imaging
Symptoms suggestive of PML* during treatment with Tysabri® (natalizumab) or other medication with similar risk * For more information about PML, see ***Background and Supporting Information***	• MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553)

Background and Supporting Information

- Multiple sclerosis is an autoimmune disease that is associated with inflammation, demyelination, and neurodegenerative changes within the optic nerves, brain, and spinal cord (i.e., central nervous system (CNS)).

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Multiple sclerosis commonly begins with a relapsing-remitting course with partial or complete neurologic recovery following acute events.
  - An acute demyelinating event lasts at least 24 hours or longer
  - Common types of MS relapses include:
    - Unilateral optic neuritis
    - Brainstem or cerebellar syndrome (i.e. trigeminal neuralgia, diplopia or intranuclear ophthalmoplegia (INO), and/or ataxia)
    - Partial transverse myelitis
- The first event concerning for demyelinating disease without meeting criteria for separation of time is known as a clinically isolated syndrome (CIS).
- Individuals who undergo a brain MRI for other indications (i.e., headaches, trauma, seizure) which incidentally reveals abnormalities that are characteristic for demyelination in the absence of clinical symptoms is known as radiologically isolated syndrome (RIS).
- Progressive Multifocal Leukoencephalopathy (PML) is a progressive multi-focal disease of the central nervous system that can occur in individuals treated with immunosuppressive or immunomodulatory medications.
  - In individuals treated with natalizumab, there is an increased risk of developing PML in individuals who:
    - Received prior immunosuppressive medication, and/or
    - Have a high JC virus antibody index, and/or
    - Received natalizumab for ≥18 months
- Interferon beta medications include (but are not limited to): Avonex®, Betaseron®, Extavia®, Plegridy®, Rebif®
- Glatiramer acetate medications include (but are not limited to): Copaxone, Glatopa®
- High-risk medications are associated with a risk of PML and/or other CNS opportunistic infections (i.e. herpes encephalitis, cryptococcal meningitis). These include (but are not limited to): Tysabri® (natalizumab), Tecfidera® (dimethyl fumarate), Gilenya® (fingolimod), Tascenso® ODT (fingolimod), Aubagio® (teriflunomide), Ocrevus® (ocrelizumab), Kesimpta® (ofatumumab), Mavenclad® (cladribine), Mayzent® (siponimod), Ponvory® (ponesimod), Vumerity® (diroximel fumarate), Zeposia® (ozanimod), Lemtrada® (alemtuzumab), Bafiertam® (monomethyl fumarate), Briumvi® (ublituximab), Rituxan® (rituximab)

Neuromyelitis Optica Spectrum Disorders (HD-16.2)

HD.MS.0016.2.A
v2.0.2026

Initial evaluation of Neuromyelitis Optica (NMO) or Neuromyelitis Optica Spectrum Disorders (NMOSD) with any of the following:

Indication	Medically Necessary Imaging
Clinical concern for optic neuritis	• MRI Orbit without and with contrast (CPT® 70543) **OR** • MRI Orbit without contrast (CPT® 70540)
Recurrent hiccups or intractable nausea and/or vomiting (clinical concern for area postrema syndrome)	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551)
Other neurologic signs or symptoms concerning for brain involvement	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging
Clinical concern for transverse myelitis	• MRI Cervical Spine without and with contrast (CPT® 72156) **OR** • MRI Cervical Spine without contrast (CPT® 72141) **AND/OR** • MRI Thoracic Spine without and with contrast (CPT® 72157) **OR** • MRI Thoracic Spine without contrast (CPT® 72146) **AND/OR** Due to potential for conus involvement: • MRI Lumbar Spine without and with contrast (CPT® 72158) **OR** • MRI Lumbar Spine without contrast (CPT® 72148)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging
Positive NMO antibody test when ordered by a neurologist or any provider in consultation with a neurologist	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551) **AND/OR** • MRI Orbit without and with contrast (CPT® 70543) **OR** • MRI Orbit without contrast (CPT® 70540) **AND/OR** • MRI Cervical Spine without and with contrast (CPT® 72156) **OR** • MRI Cervical Spine without contrast (CPT® 72141) **AND/OR** • MRI Thoracic Spine without and with contrast (CPT® 72157) **OR** • MRI Thoracic Spine without contrast (CPT® 72146)

Individual with established diagnosis of (NMOSD) with any of the following:

Indication	Medically Necessary Imaging
Clinical concern for optic neuritis	• MRI Orbit without and with contrast (CPT® 70543) **OR** • MRI Orbit without contrast (CPT® 70540)
New neurologic signs or symptoms concerning for brain involvement	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging
Clinical concern for transverse myelitis	• MRI Cervical Spine without and with contrast (CPT® 72156) **OR** • MRI Cervical Spine without contrast (CPT® 72141) **AND/OR** • MRI Thoracic Spine without and with contrast (CPT® 72157) **OR** • MRI Thoracic Spine without contrast (CPT® 72146) **AND/OR** Due to potential for conus involvement: • MRI Lumbar Spine without and with contrast (CPT® 72158) **OR** • MRI Lumbar Spine without contrast (CPT® 72148)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging
Repeat imaging for **ANY** of the following: • Re-establish baseline after starting treatment (typically 3-6 months after last MRI) • Changing disease modifying therapy (DMT) • As requested when ordered by a neurologist, neuro-ophthalmologist, ophthalmologist, or any provider in consultation with a neurologist, neuro-ophthalmologist, or ophthalmologist	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551) **AND/OR** • MRI Orbit without and with contrast (CPT® 70543) **OR** • MRI Orbit without contrast (CPT® 70540) **AND/OR** • MRI Cervical Spine without and with contrast (CPT® 72156) **OR** • MRI Cervical Spine without contrast (CPT® 72141) **AND/OR** • MRI Thoracic Spine without and with contrast (CPT® 72157) **OR** • MRI Thoracic Spine without contrast (CPT® 72146)

- For Neuromyelitis Optica Spectrum Disorder with concern for occult neoplasm, see **Paraneoplastic Syndromes (ONC-30.3)** in the Oncology Imaging Guidelines.
- Computed Tomography (CT) scans of the head and/or spine are not recommended for the evaluation of NMOSD due to inferior soft tissue resolution when compared to MRI.
- Quantitative Magnetic Resonance Image (MRI) Analysis of the Brain
  - Volumetric or quantitative analysis of the brain or temporal lobes and hippocampus may be ordered as (CPT® 0865T or CPT® 0866T).
    - These are not medically necessary in the evaluation of NMOSD.
  - Volumetric or quantitative analysis of the brain or temporal lobes and hippocampus may be ordered as 3D rendering (CPT® 76376 and CPT® 76377).
    - These studies are considered not medical necessary in the evaluation of NMOSD.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Background and Supporting Information

- Neuromyelitis optica spectrum disorder (NMOSD, Devic's disease) is a chronic inflammatory autoimmune disease that involves the optic nerves, spinal cord, and brain.
- Core clinical characteristics of NMOSD include
  - Optic neuritis
    - Frequently bilateral optic nerve involvement with severe vision loss
  - Longitudinally extensive transverse myelitis
    - Extends ≥ 3 complete vertebral segments of the spinal cord
  - Area postrema syndrome
    - Otherwise, unexplained episode of recurrent hiccups or intractable nausea and vomiting
  - Brainstem or cerebral syndrome with NMOSD typical brain lesions
  - Rarely paraneoplastic syndromes occur with NMO spectrum disorder
  - Medications used for the treatment of NMO spectrum disorders include (but are not limited to) azathioprine, Enspryng® (satralizumab), mycophenolate, Soliris® (eculizumab), rituximab, Uplizna® (inebilizumab) and Ultomiris® (ravulizumab)[54]
    - Possible adverse reactions associated with treatment include risk of PML and meningococcal infections.

Proprietary Information of UnitedHealthcare.

MOG Antibody-Associated Disease (MOGAD) (HD-16.3)

HD.MS.0016.3.A
v2.0.2026

Initial evaluation of MOG (myelin oligodendrocyte glycoprotein) antibody-associated diseases (MOGAD) with any of the following:

Indication	Medically Necessary Imaging
Clinical concern for optic neuritis	• MRI Orbit without and with contrast (CPT® 70543) **OR** • MRI Orbit without contrast (CPT® 70540)
Neurologic signs or symptoms concerning for brain involvement	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551)
Clinical concern for transverse myelitis	• MRI Cervical Spine without and with contrast (CPT® 72156) **OR** • MRI Cervical Spine without contrast (CPT® 72141) **AND/OR** • MRI Thoracic Spine without and with contrast (CPT® 72157) **OR** • MRI Thoracic Spine without contrast (CPT® 72146) **AND/OR** Due to potential for conus involvement: • MRI Lumbar Spine without and with contrast (CPT® 72158) **OR** • MRI Lumbar Spine without contrast (CPT® 72148)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging
Positive MOG antibody test when ordered by a neurologist or any provider in consultation with a neurologist	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551) **AND/OR** • MRI Orbit without and with contrast (CPT® 70543) **OR** • MRI Orbit without contrast (CPT® 70540) **AND/OR** • MRI Cervical Spine without and with contrast (CPT® 72156) **AND/OR** MRI Thoracic Spine without and with contrast (CPT® 72157) **OR** • MRI Cervical Spine without contrast (CPT® 72141) **AND/OR** MRI Thoracic Spine without contrast (CPT® 72146) **AND/OR** Due to potential for conus involvement: • MRI Lumbar Spine without and with contrast (CPT® 72158) **OR** • MRI Lumbar Spine without contrast (CPT® 72148)

Individuals with established diagnosis of (MOGAD) with any of the following:

Indication	Medically Necessary Imaging
Clinical concern for optic neuritis	• MRI Orbit without and with contrast (CPT® 70543) **OR** • MRI Orbit without contrast (CPT® 70540)
Neurologic signs or symptoms concerning for brain involvement	• MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551)

- For MOG (myelin oligodendrocyte glycoprotein) Antibody-Associated Disease with concern for occult neoplasm, see **Paraneoplastic Syndromes (ONC-30.3)** in the Oncology Imaging Guidelines.
- Computed Tomography (CT) scans of the head and/or spine are not recommended for the evaluation of MOG (myelin oligodendrocyte glycoprotein) Antibody-Associated Disease due to inferior soft tissue resolution when compared to MRI.

Background and Supporting Information

- MOG (myelin oligodendrocyte glycoprotein)-IgG disorders are CNS inflammatory diseases, distinct from multiple sclerosis and NMO-spectrum disorders.
- Unlike multiple sclerosis and neuromyelitis optica spectrum disorder (NMOSD), individuals with MOG antibody-associated disease (MOGAD) can have a monophasic or relapsing course.
  - Relapses are more common in the first six months after the first episode.
  - An acute relapse is considered when an individual with MOGAD develops new neurologic signs or symptoms at least 30 days following the previous event.
- Diagnosis is based on the clinical presentation, MRI findings, and the presence of auto-antibodies.
- Clinical features of individuals with MOGAD include
  - Optic neuritis
    - Bilateral optic neuritis is common at onset, and seems to be more frequent in individuals with MOGAD than with those with multiple sclerosis or neuromyelitis optica spectrum disorder (NMOSD).
    - Vision improves quickly with return to normal or near normal visual acuity following treatment with intravenous corticosteroids.
  - Transverse myelitis
    - Cauda equina and peripheral nerve root involvement can occur (lumbar spine imaging is medically necessary)
    - Can occur as an isolated episode of transverse myelitis, as a component of ADEM or in conjunction with optic neuritis.
    - T2 spinal cord lesions often are centrally located and can be restricted to the grey matter producing the “H sign” on MRI
    - Most T2 lesions resolve or reduce in size substantially on follow-up MRI
  - Brainstem encephalitis
  - Encephalitis with seizures
  - Acute disseminated encephalomyelitis (ADEM)
    - Occurs mainly in children but can occur in adults.
  - Tumefactive brain lesions
  - Cranial neuropathies

Transverse Myelitis (HD-16.4)

HD.MS.0016.4.A
v2.0.2026

An initial assessment, to include a pertinent history and neurologic exam, should be performed prior to imaging requests.

Clinical Concern for Transverse Myelitis

Indication	Medically Necessary Imaging
Clinical concern for transverse myelitis	• MRI Cervical Spine without and with contrast (CPT® 72156) **OR** • MRI Cervical Spine without contrast (CPT® 72141) **AND/OR** • MRI Thoracic Spine without and with contrast (CPT® 72157) **OR** • MRI Thoracic Spine without contrast (CPT® 72146) **AND/OR** Due to potential for conus involvement: • MRI Lumbar Spine without and with contrast (CPT® 72158) **OR** • MRI Lumbar Spine without contrast (CPT® 72148) **AND/OR** • MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551) If optic neuritis is suspected*, the following imaging is **ALSO** medically necessary: • MRI Orbit without and with contrast (CPT® 70543) **OR** • MRI Orbit without contrast (CPT® 70540) ***For additional information related to optic neuritis see Eye Disorders and Visual Loss (HD-32.1)**

New Neurologic Signs or Symptoms in an individual with a history of transverse myelitis (TM)

Indication	Medically Necessary Imaging
New neurologic signs or symptoms	• MRI Cervical Spine without and with contrast (CPT® 72156) **OR** • MRI Cervical Spine without contrast (CPT® 72141) **AND/OR** • MRI Thoracic Spine without and with contrast (CPT® 72157) **OR** • MRI Thoracic Spine without contrast (CPT® 72146) **AND/OR** • MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551) If optic neuritis is suspected*, the following imaging is **ALSO** medically necessary: • MRI Orbit without and with contrast (CPT® 70543) **OR** • MRI Orbit without contrast (CPT® 70540) ***For additional information related to optic neuritis, see Eye Disorders and Visual Loss (HD-32.1)**

Proprietary Information of UnitedHealthcare.

Surveillance of Transverse Myelitis

Indication	Medically Necessary Imaging Annually for 5 years
Individual with a history of transverse myelitis • Ordered by a neurologist or any provider in consultation with a neurologist	• MRI Cervical Spine without and with contrast (CPT® 72156) **OR** • MRI Cervical Spine without contrast (CPT® 72141) **AND/OR** • MRI Thoracic Spine without and with contrast (CPT® 72157) **OR** • MRI Thoracic Spine without contrast (CPT® 72146) **AND/OR** • MRI Brain without and with contrast (CPT® 70553) **OR** • MRI Brain without contrast (CPT® 70551)

- For transverse myelitis with concern for occult neoplasm, see **Paraneoplastic Syndromes (ONC-30.3**) in the Oncology Imaging Guidelines.
- Individuals with transverse myelitis present with various symptoms of sensory, motor and/or autonomic dysfunction.
  - Bilateral signs and/or symptoms (although not necessarily symmetrical)
  - Examination findings may include but are not limited to any of the following:
    - Bilateral limb weakness
    - Loss of manual dexterity
    - New or worsening foot drop
    - Sensory abnormalities
    - Sensory level
    - Hyperreflexia (including upgoing toes, positive Babinski, Hoffman's sign, clonus)
    - Gait abnormality (spastic or ataxic gait)
    - See also: *Background and Supporting Information*
  - If inflammation is identified within the spinal cord suggestive of transverse myelitis, a brain MRI is recommended to evaluate for a multifocal inflammatory process
- See **Multiple Sclerosis (MS) (HD-16.1)**, **Neuromyelitis Optica Spectrum Disorders (HD-16.2)**, **MOG Antibody-Associated Diseases (MOGAD) (HD-16.3)**

Background and Supporting Information

- Symptoms may include but are not limited to the following:
  - Motor weakness of a limb or limbs, including paraparesis and/or complete paralysis

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - Change in sensation in a limb or limbs that may be associated with paresthesias and/or dysthesias.
  - Urinary urgency, incontinence, and/or urinary retention
  - Worsening constipation and/or bowel urgency/incontinence
  - Sexual dysfunction
  - Lhermitte's sign
  - New or worsening spasticity
- Acute transverse myelitis is defined as an acute inflammatory syndrome leading to motor and/or sensory impairment, with or without sphincter dysfunction, secondary to a variety of autoimmune or inflammatory diseases.
- Diagnosed by spinal MRI and/or cerebrospinal fluid.
- Individuals typically progress to maximal neurological deficits within 4 weeks.
- Longitudinally extensive transverse myelitis (≥3 vertebral segments) is more commonly associated with neuromyelitis optica spectrum disorders (NMOSD) and/or MOG antibody-associated diseases (MOGAD)
- Transverse myelitis:
  - May be idiopathic
  - Initial event of multiple sclerosis (see **Multiple Sclerosis (MS) (HD-16.1)**
  - Initial event of neuromyelitis optica spectrum disorder (NMOSD) (see **Neuromyelitis Optica Spectrum Disorders (HD-16.2)**)
  - Initial event of MOG antibody-associated disease (MOGAD) (see **MOG Antibody-Associated Diseases (MOGAD) (HD-16.3)**)
  - May be associated with connective tissue disease
    - Systemic lupus erythematous (SLE)
    - Rheumatoid Arthritis (RA)
    - Sjögren's syndrome
    - Systemic sclerosis
  - Manifestation of neurosarcoidosis (see **Autoimmune/Paraneoplastic Encephalitis & Neuroinflammatory Disorders (HD-14.3)**)
  - Post-infectious and/or post-vaccination related
    - COVID-19 and COVID-19 post-vaccination myelitis cases have been reported (see **Neuro-COVID-19 and Sars-COV-2 Vaccines (HD-14.2)**)
    - May have a prodromal syndrome with fever, respiratory and/or gastrointestinal symptoms
    - May be associated with headache, neck stiffness or recurrence of fever

Proprietary Information of UnitedHealthcare.

Evidence Discussion (HD-16)

v2.0.2026

- Magnetic resonance imaging (MRI) is the recommended imaging modality for the diagnosis and monitoring of multiple sclerosis (MS) and other inflammatory diseases of the central nervous system (CNS). Its high sensitivity for the evaluation of inflammatory and neurodegenerative processes in the brain and spinal cord has made it the gold standard for the evaluation of individuals with MS.[8,31]
- Computed Tomography Scan (CT) is not recommended for the evaluation of MS due to inferior soft tissue resolution when compared to MRI.[28,41,42]
- MRI plays an important role in the following clinical scenarios:
  - establishing the diagnosis of multiple sclerosis (MS) by establishing evidence for dissemination in space and time.[8,31]
  - diagnostic workup. Approximately 50%-90% of individuals with MS have spinal cord lesions.[8]
  - detecting optic nerve abnormalities in individuals with symptoms concerning for optic neuritis.[7,42]
  - assessment of treatment response and in monitoring for potential treatment related safety concerns. Management and surveillance intervals are primarily consensus based and have been addressed in several evidence and practice-based guidelines.[7,8]
  - evaluation of other central nervous system (CNS) inflammatory diseases, including autoimmune disseminated encephalomyelitis (ADEM), neuromyelitis optica (NMO), myelin oligodendrocyte glycoprotein antibody-associated disease (MOGAD) and transverse myelitis (TM).[28,31,36,44]
  - detecting conus medullaris involvement in individuals with myelin oligodendrocyte glycoprotein-associated disease (MOGAD) and transverse myelitis.[28,36,44]

Papilledema/Pseudotumor Cerebri (HD-17.1)

HD.PP.0017.1.A
v2.0.2026

- See **Eye Disorders and Visual Loss (HD-32.1)**
- Papilledema and Pseudotumor Cerebri (Idiopathic Intracranial Hypertension, Benign Intracranial Hypertension):
  - MRI Orbits/Face/Neck without contrast (CPT® 70540) **OR** MRI Orbits/Face/Neck without and with contrast (CPT® 70543) **OR** CT Orbits/Temporal bone with contrast (CPT® 70481) **OR** CT Orbit/Temporal bone without contrast (CPT® 70480) **AND/OR** MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) is/are medically necessary for:
    - Suspected elevated intracranial pressure **AND/OR** papilledema
    - CT Head without contrast (CPT® 70450) is medically necessary when MRI is contraindicated or for urgent evaluation
    - See **General Guidelines – CT Head (HD-1.4)** regarding required use of CT Head prior to lumbar puncture and/or spinal tap.
    - See **Eye Disorders and Visual Loss (HD-32.1)** regarding concern for orbital pseudotumor or primary orbital disorder.
  - MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) or CTA Head (CPT® 70496) is medically necessary, in addition, for venogram when requested.
    - CT and MR Venography (CTV and MRV) are reported with the same codes as the CTA/MRA counterpart. If arterial and venous CT or MR studies are both performed in the same session, only one CPT® code should be used to report both procedures
    - See **Stroke/TIA (HD-21.1)**
    - See **Cerebral Venous Thrombosis (HD-21.8)**
  - Repeat structural and/or vascular imaging, with any of the above listed studies, for follow-up, including to confirm stent patency, and for evaluation of worsening symptoms, or suspected complications, as requested by a neurologist or a neurosurgeon or any provider in consultation with a neurologist or a neurosurgeon.
    - See also **Hydrocephalus Shunts (HD-11.14)**

Background and Supporting Information

Treatment for idiopathic intracranial hypertension (IIH) includes weight loss and acetazolamide. Surgical interventions include optic nerve sheath fenestration,

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

cerebrospinal fluid shunting, and bariatric surgeries. These surgical procedures are invasive and associated with complications.

Venous sinus stenting is a treatment option for those with idiopathic intracranial hypertension who have failed first line therapy. Prior to stenting, individuals should undergo venography. CTV and/or MRV can be performed to confirm stent patency.

Stenting improves tinnitus, papilledema, diplopia/visual disturbances, and headaches.

Post- stent complications include subdural hematoma, subarachnoid hemorrhage, worsening headaches, visual impairment, worsening papilledema, blindness, arterial dissection, and death. Venous sinus stenting has lower complications relative to surgical interventions.

Evidence Discussion (HD-17)

- In the evaluation of suspected or known intracranial hypertension and/or exam findings of papilledema, neuroimaging is helpful for diagnosis, excluding other structural causes, and for the identification of venous outflow obstruction.[2,4,5]
- MRI Brain allows detection of findings supportive of intracranial hypertension and detection of structural abnormalities such as mass, edema, or hydrocephalus.[1,2,3,5,7] MR Venogram allows identification of venous sinus stenosis and thrombosis for treatment planning in these scenarios.[2,3,5]
- Alternatively, CT Head allows exclusion of secondary causes such as hydrocephalus, mass, or edema, particularly in urgent scenarios.[1,2,5,7] CT Venogram allows direct vessel visualization to exclude venous outflow obstruction in these cases.[1,2,5]
- In addition, orbital symptoms may be evaluated with either CT Orbits or MRI Orbits, with CT providing superior bony anatomy evaluation and calcification detection and MRI providing superior soft tissue resolution and evaluation of the optic nerve.[1,5,7]

Sensory/Weakness Complaints (HD-18.1)

HD.PS.0018.1.A
v2.0.2026

Advanced imaging for complaints of sensory loss and/or paresthesias (see *Background and Supporting Information)* and/or weakness that are unaccompanied by other symptoms and not preceded by trauma must have the following: a thorough clinical history and a detailed neurological exam (including the symptomatic area).

Imaging for sensory and weakness complaints is medically necessary with the following findings:

Indications	Medically Necessary Imaging
ANY of the following: • Hyperreflexia • Babinski/Hoffman sign* • Increased tone in affected limb • Bladder and/or bowel dysfunction • Motor symptoms in ANY of the following patterns: ◦ Two limbs on same side of body ◦ Face and limb involvement • Sensory symptoms in ANY of the following patterns: ◦ Two limbs on same side of body ◦ Face and limb involvement *See ***Background and Supporting Information***	• MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553) **AND/OR** • MRI Cervical Spine without contrast (CPT® 72141) **OR** • MRI Cervical Spine without and with contrast (CPT® 72156) **AND/OR** • MRI Thoracic Spine without contrast (CPT® 72146) **OR** • MRI Thoracic Spine without and with contrast (CPT® 72157)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Findings Specific to the Spinal Cord	Medically Necessary Imaging
ANY of the following: • Decreased pinprick sensation on one side of the body with weakness and decreased proprioception on the other side • Sensory level (also called spinal cord level) on the trunk with sensory loss in both legs • Tight band around the trunk or torso • Pure sensory symptoms with proximal and distal involvement and a symmetric pattern • Decreased or absent reflexes AND noted concern for spinal cord shock or acute spinal cord injury* *See ***Background and Supporting Information***	• MRI Cervical Spine without contrast (CPT® 72141) **OR** • MRI Cervical Spine without and with contrast (CPT® 72156) **AND/OR** • MRI Thoracic Spine without contrast (CPT® 72146) **OR** • MRI Thoracic Spine without and with contrast (CPT® 72157)

Findings Specific to the Terminal End of the Spinal Cord	Medically Necessary Imaging
Concern for conus medullaris syndrome.* • Symptoms may include, but are not limited to: ◦ Saddle anesthesia ◦ Urinary retention ◦ Bowel incontinence ◦ Lower limb paresthesias ◦ Lower limb weakness *See ***Background and Supporting Information***	• MRI Lumbar Spine without contrast (CPT® 72148) **OR** • MRI Lumbar Spine without and with contrast (CPT® 72158)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- MRI Lumbar Spine is not typically medically necessary to visualize the spinal cord except in the clinical scenarios noted above. MRI Cervical Spine and MRI Thoracic Spine will image the entire spinal cord.
- Findings NOT consistent with central nervous system localization and NOT supporting brain or spinal cord imaging include:
  - Sensory loss that involves the hands and feet and not the trunk
  - Limb pain
- For symptoms after trauma, refer to **Head Trauma (HD-13.1)** and/or the appropriate level in the Spine Imaging Guidelines
- For generalized weakness, polyneuropathy, and/or other patterns of sensory and/or motor symptoms not referenced above, refer to the following guidelines:
  - Myopathy or myositis, see **Muscle Diseases (PN-8.5)** and **Gaucher Disease (Storage Disorders) (PN-8.6)**
  - Motor Neuron Disease or Amyotrophic Lateral Sclerosis (ALS), see **Motor Neuron Disease/Amyotrophic Lateral Sclerosis (ALS) (PN-8.1)**
  - Neuromuscular Junction Disorders, see **Neuromuscular Junction Disorders (PN-8.4)**
  - Multifocal Motor Neuropathy (MMN) and Chronic Inflammatory Demyelinating Polyneuropathy (CIDP), see **Polyneuropathy (PN-3.1)**
  - Polyneuropathy, see **Polyneuropathy (PN-3.1)**
  - Neuropathy with concern for malignancy, see **Paraneoplastic Syndromes (ONC-30.3)** in the Oncology Imaging Guidelines
  - Proximal asymmetric and concern for plexopathy, see **Brachial Plexus (PN-4.1)** and/or **Lumbar and Lumbosacral Plexus (PN-5.1)**
  - Sensory and/or motor symptoms localized to a single nerve, see **Focal Neuropathy (PN-2.1)**
  - Thoracic Outlet Syndrome, see **Thoracic Outlet Syndrome (CH-31.1)** in the Chest Imaging Guidelines
  - Radiculopathy, see appropriate level in the Spine Imaging Guidelines
  - Cauda Equina Syndrome, see **Red Flag Indications (SP-1.2)** in the Spine Imaging Guidelines

Background and Supporting Information

- Paresthesia refers to an abnormal sensation that is associated with nervous system dysfunction and may be described as a tingling, pricking, pins and needles, or a burning sensation. The priority is to determine whether the etiology is due to pathology of the peripheral nervous system (PNS) or central nervous system (CNS).
- A thorough clinical history, including symptom location and time course, can be helpful to differentiate PNS pathologies from CNS. For example, paresthesia affecting one side of the face and/or body (i.e., hemisensory deficit) points strongly towards

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

central nervous system dysfunction. Therefore, brain and/or spinal cord imaging may be supported based on the location of symptoms. Typically, lumbar spine imaging is not supported unless there is sphincter involvement, saddle anesthesia, and/or cauda equina syndrome is suspected. In contrast, an insidious course of distal, symmetric limb paresthesia is more commonly associated with peripheral nerve abnormalities. In such cases, NCS/EMG testing results should be completed prior to advanced imaging. (See *Peripheral Nerve and Neuromuscular Disorders Imaging Guidelines)*.

- Upper motor neuron signs (e.g., increased tone, hyperreflexia, presence of Babinski or Hoffman signs) may support a need for central nervous system imaging.
- Lower motor neuron signs (e.g., decreased tone, hypo- or areflexia, muscle atrophy) may support evaluation for peripheral nervous system diseases. Nerve conduction and needle EMG testing should be completed prior to advanced imaging.
- It is important to note that both peripheral and central nervous system disease can co-exist. As a result, if both upper and lower motor neuron signs are observed simultaneously, advanced imaging may be supported regardless of NCS/EMG testing results, (see **Polyneuropathy (PN-3.1)** in the Peripheral Nerve and Neuromuscular Disorders (PNND) Imaging Guidelines).
- Babinski sign - presence of an upgoing big toe with stimulation of the lateral plantar region of the foot.
- Hoffman sign - involuntary flexion of the fingers, particularly the thumb and index fingers, triggered by flicking the distal segment of the middle finger.
- Spinal cord shock/acute spinal cord injury - occurs after hyperacute or acute injury to the cord and presents with flaccid areflexia below the level of injury. May be associated with hypotension and/or bradycardia if loss of sympathetic tone occurs. Signs may last from days to weeks before upper motor neuron findings develop.
- Conus Medullaris Syndrome - compressive damage to the spinal cord from T12-L2. Symptoms suggestive of conus medullaris syndrome include saddle anesthesia, urinary retention, bowel incontinence, and/or lower extremity motor or sensory changes.

Evidence Discussion (HD-18)

- The imaging modality of choice for the evaluation of signs or symptoms localizing to the spinal cord is with MRI.[3,4,5,10,11] MRI allows visualization of the soft tissues and structures that comprise the neural axis.[3,10,11] Imaging of the cervical and thoracic segments are sufficient to view the entire spinal cord.[4,10]
- MRI of the lumbar spine is reserved for the evaluation of conus and the cauda equina.[4]
- For evaluation of isolated distal symmetric polyneuropathy, MRI of the brain and/or spine rarely change management in these individuals despite being frequently performed. MRI has little role in these scenarios as it evaluates the central nervous system.[7]

Pituitary (HD-19.1)

HD.PT.0019.1.A
v2.0.2026

- Endocrine laboratory studies should be performed prior to considering advanced imaging, except in the cases of stable, non-functioning microadenomas or macroadenomas, cysts, and/or for incidentally found lesions.
- MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551) with a specific pituitary protocol that includes fine cuts through the sella is medically necessary as the primarily performed pituitary imaging:
  - MRI Orbit/Face/Neck without and with contrast (CPT® 70543) or CT Head without and with contrast (CPT® 70470) are medically necessary alternatives
  - CT Head without contrast (CPT® 70450) or without and with contrast (CPT® 70470) **AND/OR** CT Maxillofacial without contrast (CPT® 70486) is medically necessary in addition to MRI to visualize perisellar bony structures in the pre-operative evaluation of certain sellar tumors and for pre-operative planning for transphenoidal approaches
    - See **General Guidelines – Anatomic Issues (HD-1.1)** as CT Temporal bone (CPT® 70480) is medically necessary instead of CT Maxillofacial per surgeon's preference and contrast level
  - CTA Head (CPT® 70496) or MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) is medically necessary for surgical planning
  - MRI Brain without and with contrast (CPT® 70553) covers both brain and dedicated pituitary if performed at the same time; no additional CPT® codes are medically necessary
- Medically necessary repeat imaging for incidentally found lesions on other studies:
  - MRI Brain without and with contrast (CPT® 70553) or MRI Orbit/Face/Neck without and with contrast (CPT® 70543) follow-up dedicated pituitary study obtained if a pituitary abnormality is reported incidentally on a MRI Brain or CT Head performed for other reasons (MRI Brain without and with contrast [CPT® 70553] covers both brain and dedicated pituitary if performed at the same time; no additional CPT® codes are needed); further evaluation and subsequent imaging dependent on specific imaging and biochemical laboratory evaluation findings.
- Repeat imaging in the setting of worsening clinical status or new neurologic symptoms
- See in the Pelvic Imaging Guidelines for initial lab and imaging work up to exclude other causes. See Female Hypogonadism or Prolactinoma or other relevant sections in the grid if suspicion for pituitary tumor/disease or **Craniopharyngioma and Other Hypothalamic/Pituitary Region Tumors (HD-19.4)** for suspicion of hypothalamic causes.

Pituitary Imaging

Indication	Medically Necessary Initial Imaging	Medically Necessary Repeat Imaging
Microadenoma: Nonfunctioning, unexplained pituitary asymmetries, or incidentally found small tumors (<10 mm)	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551)	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551) at 12 months and then (if stable in size), every 1-2 years for 3 years, and less frequently thereafter based on clinical status
Macroadenoma (≥10 mm): Nonfunctioning and/or not surgically removed including those with a post-operative remnant	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551)	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551) every 6 months for the first year and then (if stable in size), every year for 3 years, and less frequently thereafter based on clinical status (longer if craniopharyngioma)
Acromegaly* (Elevated IGF-1 confirmed by lack of suppression of growth hormone on glucose suppression testing)	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551)	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551) ◦ At least 12 weeks after surgery to evaluate for residual tumor ◦ If treated with Pegvisomant, 6 to 12 months after treatment initiated, then annually if stable ◦ Long-term follow-up imaging based on clinical and biochemical status at the request of a specialist or any provider in consultation with a specialist

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Initial Imaging	Medically Necessary Repeat Imaging
Cushing's Disease** (Pituitary ACTH excess leading to hypercortisolism)	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551)	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551) ◦ At least 12 weeks after surgery as new baseline ◦ Annually after bilateral adrenalectomy for Cushing's disease or ectopic ACTH production ◦ Long-term follow-up imaging based on clinical and biochemical status at the request of a specialist or any provider in consultation with a specialist
Rathke's cleft cyst/ Simple cyst	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551)	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551) in one year; if stable and without mass effect or invasion into surrounding structures, no further imaging is required.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging
Prolactinomas* **	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551) with: ◦ Diagnosis: ▪ Unexplained prolactin level above the normal range ◦ On Dopamine Agonist (DA) therapy with good response: ▪ Macroadenomas 3 months after start of DA therapy ▪ Microadenomas 1 year after start of DA therapy ▪ To decide on stoppage of therapy after ~2 years if in “remission” (normal PRL and no visible tumor on MRI) ◦ On Dopamine Agonist therapy with suboptimal response: ▪ PRL levels rise ▪ New symptoms develop (galactorrhea, vision changes, headaches, pituitary deficiency) ▪ If on high dose maximal DA and no plans for surgery/radiation therapy use guideline for microadenoma or macroadenoma ◦ After Dopamine Agonist therapy: ▪ Rise in PRL level ▪ For DA stoppage at menopause, use guideline for microadenoma or macroadenoma ◦ Not on therapy – refer to recommendations for repeat imaging for microadenoma or macroadenoma ◦ Galactorrhea/nipple discharge with normal prolactin and thyroid function levels: See **Nipple Discharge/ Galactorrhea (BR-6.1)** in the Breast Imaging Guidelines
Medication-induced Prolactinemia**	• To differentiate between medication-induced hyperprolactinemia and hyperprolactinemia due to a pituitary or hypothalamic mass if the medication cannot be discontinued or hyperprolactinemia persists after medication discontinuation

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging
TSH, FSH, or LH producing adenomas (inappropriate pituitary hypersecretion of TSH, FSH or LH)***	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551) when hormone levels are inappropriately elevated and there is a concern for a pituitary lesion. • Refer to appropriate post-operative, or Microadenoma/ Macroadenoma guidelines based on the size of the lesion and initial management. ◦ Long-term follow-up imaging based on clinical and biochemical status at the request of a specialist or any provider in consultation with a specialist
Male Hypogonadism****	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551) if **ONE** of the following: ◦ Severe secondary hypogonadism (as indicated by morning serum testosterone level <150 ng/dl and low or normal LH and FSH levels) (See *Background and Supporting Information*) ◦ Below normal testosterone level (serum total testosterone, free testosterone, and/or bioavailable morning testosterone) AND low or normal LH and FSH levels, in an individual with either: ▪ Panhypopituitarism ▪ Hyperprolactinemia ▪ Signs of tumor mass effect (headache, visual impairment, or visual field deficit) ▪ Elevated sex hormone binding globulin (SHBG)
Female Hypogonadism (Secondary Amenorrhea may be a feature)	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551) for normal or low FSH with low estradiol (LH may be normal or low also)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging
Growth Hormone Deficiency (Adult onset)	MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551) for the following: • Low Growth Hormone (GH) **OR** • Low IGF-1 **AND** • One abnormal provocative test (likely will be Glucagon Stimulation test as GNRH is unavailable and Insulin Tolerance test poses risks) • If 3 or more pituitary hormones are deficient (including GH), then provocative test is not needed.
Secondary (Central) Adrenal Insufficiency	MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551) for the following: • ACTH is low or normal at 10 or lower **AND** • Low baseline cortisol level <3 µg/dL **OR** • abnormal ACTH stimulation test with suboptimal cortisol stimulation where cortisol does not reach above 18 µg/dL
Central Hypothyroidism	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551) for the following: ◦ Low free T4 with normal, low, or mildly elevated TSH
Hypopituitarism **(deficiency of one or more pituitary hormones)**	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Initial Imaging	Medically Necessary Repeat Imaging for Non-Operative Care
Diabetes Insipidus (DI) - ADH deficiency	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551) if: ◦ Laboratory testing consistent with DI (serum osmolality should be high and urine osmolality should be low) and etiology uncertain	NA
Syndrome of Inappropriate ADH (SIADH)	• MRI Brain without and with contrast (CPT® 70553) or MRI Brain without contrast (CPT® 70551) if: ◦ Etiology remains uncertain or is thought to be in the nervous system ◦ Urine osmolality should be high and serum osmolality low	NA
Other Pituitary Region Tumors	• Evaluation may require CT in addition to MRI to evaluate for hyperostosis.	

Background and Supporting Information

- ***Acromegaly:** A serum level of growth hormone greater than 1ng/mL when measured two hours following an oral glucose load confirms acromegaly.
- ****Cushing's Disease:** It is important to differentiate Cushing's syndrome (hypercortisolism from any source) from Cushing's disease which is ACTH hypersecretion from the pituitary gland. Hypercortisolism is quantified by 24hour urine cortisol collection, low dose dexamethasone suppression test and/or late-night salivary cortisol measurement. ACTH is elevated or inappropriately normal in Cushing's disease and ectopic sources of ACTH production but suppressed in other causes of hypercortisolism. A high dose dexamethasone suppression test can help determine if the elevated ACTH is from a pituitary or ectopic source. Petrosal sinus sampling may be required for tumor localization pre-operatively in the setting of a normal pituitary MRI or a small adenoma. These tumors may be managed with surgery, medical therapy, radiation, and/or bilateral adrenalectomy.
- ***Prolactinoma:** To establish the diagnosis of hyperprolactinemia, a single measurement of serum prolactin is recommended; a level above the upper limit of normal confirms the diagnosis as long as the serum sample was obtained without excessive venipuncture stress. Pregnancy and primary hypothyroidism should be

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

excluded as physiologic causes of prolactin elevation and medications that may be contributing to prolactin elevation should be considered. Dopamine agonist therapy is typically stopped during pregnancy, monitoring of prolactin levels ceases. Routine imaging surveillance during pregnancy is not recommended due to risk to fetus. Repeat imaging with MRI without gadolinium can be performed however for new or worsening symptoms, such as headaches or visual symptoms.

- **** **Medication-induced prolactin elevation:** Medication induced hyperprolactinemia is seen most commonly with antipsychotics/neuroleptics and antidepressants but may also be seen with some anti-emetics and antihypertensive agents. In individuals on prolactin elevating drugs, a prolactin level should be repeated after withdrawal of medications for 72 h, however, this approach may not be safe if this treatment is offered for psychiatric indications. If stopping the drug is not feasible, pituitary MRI is advised to rule out a sellar/parasellar tumor.
- *****TSH, FSH, or LH producing adenomas:** These are the least common of all hormonally active pituitary tumors. Individuals with TSH secreting adenomas have inappropriate TSH elevation in the setting of hyperthyroidism (elevated thyroid hormone levels). Almost all gonadotroph adenomas are clinically non-functioning. The infrequent presentation of a functioning gonadotroph adenoma should be differentiated clinically from appropriate FSH and LH elevation seen in low estrogen states (including menopause) as well as primary hypogonadism (testicular failure). Functioning TSH, FSH or LH pituitary adenomas may be managed with surgical, radiation and/or medical therapies.
- ******Male Hypogonadism:** Alterations in sex hormone-binding globulin (SHBG) can impact testosterone levels. Free or bioavailable testosterone concentrations should be measured when total testosterone concentrations are close to the lower limit of the normal range and when altered SHBG levels are suspected (e.g. moderate obesity, nephrotic syndrome, hypo- and hyperthyroidism, use of glucocorticoids, progestins, estrogens, and androgenic steroids, anticonvulsants, acromegaly, diabetes mellitus, aging, HIV disease, liver cirrhosis, hepatitis). LH and FSH should be obtained to evaluate for secondary (central) hypogonadism once low testosterone level is confirmed. Morning testosterone level is drawn anytime before 10 am for a typical sleep-wake cycle.
- Central hypothyroidism is an anatomic or functional disorder of the pituitary gland or the hypothalamus, resulting in altered TSH secretion. Diagnosis is usually made biochemically with low circulating free T4 (FT4) concentrations associated with low/normal serum TSH levels.

Post-Operative and Repeat Imaging Indications (HD-19.2)

HD.PT.0019.2.A

v2.0.2026

- For imaging in the immediate post-operative period or for acute surgical complications
  - See **Primary Central Nervous System Tumors (ONC-2.1)** in the Oncology Imaging Guidelines.
- A routine post-operative MRI is generally done at 3 months and/or at the discretion of, or in consultation with an Endocrinologist, Neurologist, Neurosurgeon, ENT, Ophthalmologist, Neuro-Ophthalmologist or Radiation Oncologist.
- Frequency of follow-up imaging depends on the post-operative size and/or functional status of the pituitary adenoma. Refer to the grid sections for Microadenoma/ Macroadenoma as well as those for disorders of pituitary hormone excess.
- Individuals with hyper-functioning tumors such as acromegaly, Cushing's disease, and excess TSH secretion may be treated with a combination of surgery, medical therapy, and radiation. Long-term monitoring of clinical status and repeat imaging at the discretion of, or in consultation with an Endocrinologist, Neurologist, Neurosurgeon, ENT, Ophthalmologist, Neuro-Ophthalmologist or Radiation Oncologist.

Empty Sella Turcica (HD-19.3)

HD.DPT.0019.3.A

v2.0.2026

- Enlarged/Empty Sella Turcica: An enlarged sella turcica without evident tumor is an incidental finding on MRI Brain or CT Head from a defect in the dural diaphragm of the sella (especially if there is elevated intracranial pressure from another cause), pituitary surgery, or as a result of a pituitary tumor which has expanded the sella and then infarcted (pituitary apoplexy).
- MRI Brain without and with contrast (pituitary protocol) (CPT® 70553) with thin sections of pituitary or MRI Brain without contrast (CPT® 70551) is medically necessary. CT Head without and with contrast (CPT® 70470) – If MRI is contraindicated.
  - Primary Empty Sella:
    - Incidentally found on other studies, asymptomatic and no related abnormalities: follow-up at 2 years. No further imaging unless clinical symptoms develop (neuro-/ophthalmological symptoms, intracranial hypertension, or endocrine/hormonal abnormalities).
    - Following medical or surgical treatment of related endocrine, neurological, or ophthalmological problems: follow-up imaging every 6 months in the year after treatment and/or at the request of a specialist or any provider in consultation with a specialist (see **Papilledema/Pseudotumor Cerebri (HD-17.1)** for additional imaging recommendations)
  - Secondary Empty Sella
    - Imaging according to the cause or if clinical disease progression (such as adenomas, infiltrative or malignant disorders, hormonal abnormalities, neuro-/ophthalmological symptoms)

Evidence Discussion (HD-19)

v2.0.2026

- MRI imaging of the Sella region using high-resolution pituitary protocols is the preferred diagnostic imaging modality for evaluation of the pituitary and sellar regions and is considered the gold standard for imaging the pituitary gland when there is suspicion of hypothalamic pituitary disease.[8]
- Both the anatomy and pathology of the pituitary gland and surrounding areas including optic chiasm, infundibulum, and vascular structures, as well as an empty sella, are reliably depicted on MRI.[8]
- MRI is the most sensitive imaging study for evaluating pituitary disease.[8]
- CT of the Sella can be used to detect bone destructive lesions of the skull base, such as craniopharyngiomas, menigiomas, or larger pituitary macroadenomas, but CT is insensitive when compared to MRI for pituitary pathology.[8]
- MRI utilizes a magnetic field and radio waves with computer processing to produce detailed images whereas CT uses ionizing radiation. Radiation dosages vary based on many factors and can be harmful to tissues. Thus, from radiation safety perspective MRI should be utilized when appropriate and supported by existing literature.[27]

Scalp and Skull Lesions (HD-20.1)

HD.SK.0020.1.A
v2.0.2026

The majority of these are benign soft tissue or bony lesions easily defined by physical examination or with skull x-rays or ultrasound.

- Ultrasound is the initial imaging of scalp lesions
- X-ray is the initial imaging of skull (bony) lesions
- CT Head without or without and with contrast (CPT® 70450 or CPT® 70470) is medically necessary for the following scenarios:
  - Any lesion on physician examination and skull x-ray or ultrasound which is not clearly benign.
  - In cases where surgical planning is in progress, x-rays and/or ultrasound are not required.
  - When bony lesions are detected on physical examination with any of the following:
    - Signs or symptoms of Langerhan's cell histiocytosis
    - Signs or symptoms of multiple myeloma
    - History of a cancer condition with a suspicion of metastasis
    - History of Paget's disease
    - History of radiation therapy to the head region
- MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) is medically necessary if there is concern for intracranial extension.
- See **Dental/Periodontal/Maxillofacial Imaging (HD-30.2)** for mandibular masses
- The following imaging is medically necessary for children and adults with Pott Puffy Tumor:
  - MRI Brain without and with contrast (CPT®70553) or CT Head without and with contrast (CPT® 70470)
  - Repeat imaging is medically necessary if requested by a neurologist, neurosurgeon, otolaryngologist (ENT) and/or oromaxillofacial surgeon (OMS) or any provider coordinating care with a neurologist, neurosurgeon, otolaryngologist (ENT) and/or oromaxillofacial surgeon (OMS)

Background and Supporting Information

Pott Puffy Tumor is an abscess involving the frontal bone with adjacent osteomyelitis as the result of a frontal sinus infection that spreads contiguously through the wall of the sinus or through hematogenous spread via the veins that drain sinus mucosa.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion (HD-20.1)

- The ACR Practice Parameter or the Performance of Computed Tomography (CT) of the head and of the extracranial head and neck gives a broad description of some of the pathologies that would be beneficially imaged using this modality, and points out that the reason for imaging must be for a valid medical reason and should be done with the aim for using only the minimum necessary radiation. This in some cases requires the use of additional modalities.[1,7]
- The majority of skull lesions is benign, but advanced imaging characteristics may aid in defining the lesion as having a relatively high pretest probability of malignancy (prior to histological confirmation). However, clinical contextual information is necessary to help decide which individuals would benefit from advanced imaging including the individual's age and features of the individual's presenting history.[6]
- Ultrasound offers many radiographic advantages for the characterization of scalp masses, which are not visualized by CT or MRI, the primary goal being to differentiate benign vs. malignant scalp masses. Cancers of the scalp represent 2% of all skin cancers. In both squamous and basal cell carcinomas, the US shows hypoechoic solid tumors with increased vascularity, and basal cell pathology can also consist of hyperechoic spots internally.[8]
- In folliculotropic mycosis fungoides (FMF), the most common manifestation of cutaneous T-cell lymphoma, the sonographic features include skin thickening, and hypoechoic upper dermis and hair follicles, with large surrounding hyperechoic deposits.[8]
- Skull (bony) lesions are most often discovered incidentally either clinically or as a result of CT or MRI of the brain performed for another indication, and these skull masses can be either malignant or benign. The individual's history is essential to understand along with the imaging characteristics in order to obtain accurate diagnosis. Radiographic features, both CT- and MRI- specific can be used to differentiate between benign and malignant lesions, identifying whether lesions have well-defined borders, sclerotic margins, and a narrow transition zone.
- The presence of bony destruction is a useful observation, periosteal reaction, soft tissue component, and intracranial or extracranial extension can be identified as malignant features in addition, and patterns such as lytic vs. sclerotic, dingle vs multiple, homogeneous vs varied composition also can give helpful information for diagnosis, and various patterns are recognizable that may support the tissue type of origin such as fibrogenic, chondrogenic, osteogenic, vascular, etc.[6]
- Plain radiograph can identify some of these features as a first diagnostic study, but advanced imaging may be necessary, in conjunction with x-ray, and at times CT and MRI are useful as complementary studies.[9]
- Pott puffy tumor is a rare complication of sinusitis or trauma, and early diagnosis is important since it is treatable with broad spectrum antibiotics, therefore advanced imaging is medically necessary with a clinical suspicion.[10]

Skull Base Osteomyelitis (SBO) (HD-20.2)

HD.SK.0020.2.A

v2.0.2026

- Note: SBO may occur from the temporal bones or paranasal sinuses and imaging should be of the region of origin
- Any of the following imaging studies are medically necessary in the diagnosis and treatment of skull base osteomyelitis and/or necrotizing external otitis:
  - MRI Brain without and with contrast (with IAC views) (CPT® 70553)
  - CT Temporal bone without contrast (CPT® 70480)
  - CT Temporal bone with contrast (CPT® 70481)
  - CT Maxillofacial without contrast (CPT® 70486)
  - CT Maxillofacial with contrast (CPT® 70487)
  - CT Neck with contrast (CPT® 70491)
  - CTA/CTV Head (CPT® 70496)
  - MRA/MRV Head, contrast as requested (CPT® 70544, 70545, 70546)
  - Gallium-67 Scan (CPT® 78800 or 78801, and 78803, 78831, 78830 or 78832)
  - Bone Scan (CPT® 78830 or 78832)
    - Skull base osteomyelitis: + Gallium and + Bone scan
    - Necrotizing otitis externa: + Gallium and - Bone scan
  - Indium WBC (CPT® 78800 or 78801, and 78803, 78831, 78830 or 78832) is medically necessary as a substitute for or used in addition to Gallium scanning to evaluate response to therapy and especially in cases that have undergone surgical debridement.
- Treatment response: Gallium-67 Scan every 4-6 weeks till scan is negative
- Surveillance Scanning: Gallium-67 Scan at 4 weeks and 3 months post-treatment
- For CT Head imaging, see General Guidelines - CT Head (HD-1.4) and/or Headache (HD-11)
- Internal Auditory Canal: (IAC) MRI can be reported as a limited study with one code from the set (CPT® 70540, CPT® 70542, or CPT® 70543), but should not be used in conjunction with MRI Brain codes (CPT® 70551, CPT® 70552, or CPT® 70553) if IAC views are performed as part of the brain.

Background and Supporting Information

Skull base osteomyelitis is a rare complication of otitis externa. It occurs most commonly among the immunocompromised, older members (greater than 65 years of age) and members with diabetes.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

MRI Brain will be positive earliest in the disease process. CT scans will best define bony destruction and are positive later in the disease process.

Evidence Discussion (HD-20.2)

- CT, although involves radiation, is more readily available and provides superior information regarding bony erosion and/or demineralization in the individual with suspected osteomyelitis.[5]
- MRI can assist with early detection of bone changes in as early as 3-5 days from onset of osteomyelitis.[5] In cases of diabetic osteomyelitis MRI provides a sensitivity of 90% and a specificity of 79%. MRI provides superior soft tissue detail and intracranial involvement secondary to its superior resolution when compared to CT for evaluation of skull-base osteomyelitis.[5,11,12]
- Both nuclear imaging by means of Technetium 99m (^{99m}Tc) and Gallium 67 (^{67}Ga) scan can assist in localizing infection. The Gallium scan is often used to determine the resolution of the infection and thus the end of antibiotic therapy.[11,12] The Technetium 99m scan can be useful for detecting the infection however often times remains positive prolonged period of time, and thus should not be used to determine resolution of infection.[12]

Stroke/TIA (HD-21.1)

HD.HL.0021.1.A
v2.0.2026

Indications	Medically Necessary Imaging
• Acute ischemic stroke • Transient ischemic attacks (TIA) • Suspected hemorrhagic stroke • Suspected subdural hemorrhage	**ANY** or **ALL** of the following: • CT Head without contrast (CPT® 70450) • CTA Head (CPT® 70496) **AND/OR** CTA Neck (CPT® 70498) ◦ CTA Head and Neck (CPT® 70471) must be substituted if performed during the same session • CT Perfusion (CPT® 70472 or 70473) • MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) • MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) • MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549
Repeat imaging for follow-up and resolution of stroke or hemorrhage	• As requested by a neurologist, neurosurgeon, hematologist, or physiatrist (PM&R), or any provider in consultation with a neurologist, neurosurgeon, hematologist, or physiatrist
Contraindication to MRI	• CT Head without contrast (CPT® 70450) **OR** • CT Head without and with contrast (CPT® 70470)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indications	Medically Necessary Imaging
Arterial Vascular Imaging supported for TIA/Stroke evaluation including dissection: • Supported concurrently with brain imaging	• MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **OR** • CTA Head (CPT® 70496) **AND/OR** • MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) **OR** • CTA Neck (CPT® 70498) **OR** • CTA Head and Neck (CPT® 70471) if performed during the same session
Venous vascular imaging for evaluation of venous infarcts	• MRA/MRV ([CPT® 70544, CPT® 70545, or CPT® 70546]) **OR** • CTA/CTV Head (CPT® 70496) **AND/OR** • MRI Brain without contrast (CPT® 70551) • MRI Brain without and with contrast (CPT® 70553) **OR** • CT Head without contrast (CPT® 70450) Also see **Cerebral Venous Sinus Thrombosis (HD-21.8)**
Cervicocerebral Catheter Angiography for stroke evaluation	• 3D Rendering (CPT® 76377 or CPT® 76376)
Stroke in Pregnancy and other hypercoagulable states • See arterial and venous vascular imaging studies above for vascular imaging requests • See *Background and Supporting Information*	• MRI Brain without contrast (CPT® 70551) **OR** • CT Head without contrast (CPT® 70450)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indications	Medically Necessary Imaging
Amaurosis Fugax or Ocular Microembolism • May include optic nerve/retinal arterial or Hollenhorst plaques on exam	See above for TIA or New Stroke brain imaging options and vascular imaging
Reversible Cerebral Vasoconstriction Syndrome	See also **Sudden Onset of Headache (HD-11.3)**
Neurologic signs and/or symptoms, including headaches, associated with COVID-19 infection and/or COVID-19 vaccination (Ischemia may be arterial or venous)	• MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553) See also **General Guidelines-CT head (HD-1.4)**, **Abnormal Blood Clotting (HD-11.9),** and **Neuro-Covid-19 (HD-14.2)**, and **Cerebral Venous Sinus Thrombosis (HD-21.8)**
Adults with HbSS (Sickle cell disease) or HbSb Thalassemia	One time MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) for screening to detect silent cerebral infarcts Follow-up or repeat testing per neurologist or hematologist or in consultation with a neurologist or hematologist See also **Sickle Cell Disease (HD-21.6)**
Secondary work-up of stroke/TIA	Transcranial Doppler Studies See **Transcranial Doppler CPT® 93886 (HD-24.8)**
Moyamoya Disease when surgery or other vascular intervention is being considered	See **Moyamoya Syndrome/Disease (HD-21.5)**
Evaluation of paradoxical venous thromboembolism in cryptogenic stroke with PFO	See **Acute deep venous thrombosis (DVT) (PVD-12.2)** and **Cryptogenic Stroke (HD-21.3)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indications	Medically Necessary Imaging
Cerebral Amyloid Angiopathy (CAA)	• MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553) **OR** • CT Head without contrast (CPT® 70450) Amyloid-PET Brain (CPT® 78811 or CPT® 78814) is considered not medically necessary for stroke evaluation. See **Mild Cognitive Impairment (MCI) and Dementia - PET (HD-8.2)**
Multisystem Smooth Muscle Syndrome/ Smooth Muscle Dysfunction Syndrome	See **Multisystem Smooth Muscle Syndrome/Smooth Muscle Dysfunction Syndrome (HD-21.7)**

Background and Supporting Information

- Pregnancy is an independent risk factor for stroke. Additional risk factors are not required for assessment of a stroke/TIA with acute focal neurological deficits.
- Additional arterial and venous hypercoagulable states that impose a stroke risk include:
  - Antiphospholipid syndrome
  - Hyperhomocysteinemia
  - Factor V Leiden mutation
  - Prothrombin gene mutation
  - Protein S deficiency
  - Protein C deficiency
  - Anti-thrombin deficiency

Proprietary Information of UnitedHealthcare.

Risk Assessment for Extracranial Carotid Disease (HD-21.2)

HD.HL.0021.2.A

v2.0.2026

- Duplex Ultrasound Carotid Arteries (CPT® 93880 or CPT® 93882) is medically necessary for the following:
  - Asymptomatic or symptomatic cervical bruits;
  - Clinical suspicion of extracranial carotid occlusion and the rationale is included
  - Pulsatile neck mass
  - Evaluation of blunt or penetrating neck trauma
  - Amaurosis fugax or ocular microembolism (optic nerve/retinal arterial or Hollenhorst plaques seen on exam)
  - Recent history of focal cerebral or ocular transient ischemic attacks
- Follow-up with CTA or contrast enhanced MRA
  - CTA and contrast enhanced MRA are comparable non-invasive imaging alternatives each with their own advantages and disadvantages
- For additional indications for Duplex Ultrasound Carotid Arteries
  - See **Initial Imaging (PVD-3.1)** in the Peripheral Vascular Disease (PVD) Imaging Guidelines
- For repeat (Surveillance) Duplex Ultrasound Carotid Arteries (CPT® 93880 or CPT® 93882)
  - See **Surveillance Imaging with NO History of Carotid Surgery or Intervention (PVD-3.2)** and **Surveillance Imaging WITH History of Carotid Surgery or Intervention (PVD-3.3)** in the Peripheral Vascular Disease (PVD) Imaging Guidelines.

Cryptogenic Stroke (HD-21.3)

HD.ST.0021.3.A
v2.0.2026

- 25% of individuals with ischemic stroke have no probable cause and is considered cryptogenic after a standard workup including an echocardiogram, inpatient cardiac telemetry or 24-Holter monitoring, CT or MRI Brain and vessel imaging of the brain or neck arteries and hematologic tests.
- A stroke may also be considered cryptogenic after a standard evaluation fails to yield an etiology in an individual <50 years of age without risk factors with more extensive testing.
- Most cryptogenic sources are embolic in etiology from venous or arterial sources with investigations from disturbances in coagulation and sources of embolism including patent foramen ovale (PFO) and paroxysmal atrial fibrillation.
- Specialized evaluation with the following documentation:
  - MRI/CT Brain with results of stroke
  - Results of MRA/CTA Head and Neck
  - TTE or TEE
  - 24-Hr Holter monitor or Inpatient cardiac telemetry and 12-Lead ECG
- Hematologic testing to include: CBC, Platelet count, INR, PT, PTT, D-Dimer and Arterial and Venous Hypercoagulability tests
  - MRA or CTA Pelvis for the evaluation of paradoxical venous thromboembolism with PFO
    - See **Acute Limb Swelling (PVD-12)** in the Peripheral Vascular Disease (PVD) Imaging Guidelines.
  - Work-up for occult cancer, CT Chest, Abdomen, and/or Pelvis with contrast after the previously indicated tests with results are provided.
    - See **Paraneoplastic Syndromes (ONC-30.3)** in the Oncology Imaging Guidelines.

Transient Global Amnesia (HD-21.4)

HD.ST.0021.4.A

v2.0.2026

- Transient Global Amnesia (TGA) is a clinical diagnosis with the differential diagnosis including, but not exclusive to: ischemic events, migraine headaches, and transient epileptic amnesia.
- Characteristics of TGA may include the following:
  - Inability to retain new information, lasting for several hours with preservation of alertness and all other cognitive functions with repetitive queries and amnesia
  - Witnessed episode
  - There must be anterograde amnesia during the attack
  - Cognitive impairment is limited to amnesia
  - No clouding of consciousness or loss of personal identity
  - No focal neurological signs/symptoms
  - No epileptic features
  - Attack must resolve within 24 hours
  - No recent head injury or active epilepsy
- Head and vessel imaging for ischemic etiology work-up should follow **Stroke/TIA (HD-21.1)**
- For suspected seizure, see **Epilepsy/Seizures (HD-9.1)**

Moyamoya Syndrome/Disease (HD-21.5)

HD.ST.0021.5.A
v2.0.2026

Initial imaging for Moyamoya Syndrome/Disease

- The imaging listed below is medically necessary for initial evaluation of Moyamoya Syndrome/Disease:
  - MRI Brain without contrast (CPT® 70551) **OR**
  - MRI Brain without and with contrast (CPT® 70553) **AND/OR**
  - MRA Head (CPT® 70544, CPT® 70545, **OR** CPT® 70546) **AND/OR**
  - MRA Neck (CPT® 70547, CPT® 70548 **OR** CPT® 70549)
    - If MRA is contraindicated or not readily available, then CTA Head (CPT® 70496) **AND/OR** CTA Neck (CPT® 70498) **OR** CTA Head and Neck (CPT® 70471) must be substituted if performed during the same session is/are medically necessary

Repeat imaging for Moyamoya Syndrome/Disease

- MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **AND/OR** MRA Neck (CPT® 70547, CPT® 70548 or CPT® 70549)
  - Follow-up or repeat testing per neurologist, neurosurgeon, hematologist or in consultation with a neurologist, neurosurgeon, or hematologist.
  - If MRA is contraindicated or not readily available, then CTA Head (CPT® 70496) AND/OR CTA Neck (CPT® 70498) **OR** CTA Head and Neck (CPT® 70471) must be substituted if performed during the same session is/are medically necessary.
- MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553)
  - Follow-up or repeat testing per neurologist, neurosurgeon, hematologist or in consultation with a neurologist, neurosurgeon, or hematologist.
- Radiopharmaceutical Localization Imaging SPECT (CPT® 78803, CPT® 78830 or CPT® 78832) with vasodilating agent acetazolamide (Diamox) challenge is supported when surgery or other vascular intervention is considered. Follow-up or repeat testing per neurologist, neurosurgeon, hematologist or in consultation with a neurologist, neurosurgeon, or hematologist.
- 3D Rendering (CPT® 76377 or CPT® 76376) with cerebral angiography is medically necessary to define the presence, location, and anatomy of intracranial and cervical vascular malformations.
  - See **General Guidelines – Other Imaging Situations (HD-1.7)** and in the Preface Imaging Guidelines

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- CT Perfusion (CPT® 70472 or 70473) **OR** MRI Perfusion (CPT® 70551 OR CPT® 70552 OR CPT® 70553) is medically necessary for any of the following:
  - When requested by neurologist and/or neurosurgeon
  - Prior to change in treatment
  - Post-surgical

Screening imaging for Moyamoya Disease

- Screening is not medically necessary for Moyamoya Syndrome.
  - See *Background and Supporting Information*
- Screening for Moyamoya Disease is medically necessary for:
  - First-degree relatives (biological parent, full sibling, or biological child) of individuals with Moyamoya Disease when requested by, or any provider in consultation with, a neurologist, geneticist, or neurosurgeon
- The imaging listed below is medically necessary for screening evaluation of Moyamoya Disease:
  - MRA Head (CPT® 70544, CPT® 70545, **OR** CPT® 70546) **OR** Transcranial Doppler (TCD) Ultrasound (CPT® 93886 or CPT® 93888) (see **Transcranial Doppler (CPT® 93886) (HD-24.8)** in the Head Imaging Guidelines)
  - If MRA is contraindicated or not readily available, then CTA Head (CPT® 70496) is medically necessary

CT Perfusion (CPT® 70472 or 70473)

- Is medically necessary if requested by a neurologist, neurosurgeon or any provider coordinating care with a neurologist or neurosurgeon

MRI Perfusion

- MRI Perfusion may be obtained with MRI Brain (CPT® 70551 OR CPT® 70552 OR CPT® 70553)
  - No additional CPT® codes are medically necessary or appropriate to perform MRI perfusion.

Background and Supporting Information

Moyamoya disease (MMD) is a rare cerebrovascular disease characterized by progressive spontaneous bilateral occlusion of the intracranial internal carotid arteries (ICA) and their major branches (middle cerebral artery, MCA, and anterior cerebral artery, ACA) with compensatory capillary collaterals as an expression of pathologically increased angiogenic activity resembling a "puff of smoke" (Japanese: Moyamoya) on cerebral angiography. Moyamoya Disease is most prevalent individuals with East Asian

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

ancestry. Up to 15% of individuals with Moyamoya Disease may have a family history of Moyamoya Disease.

Moyamoya Disease is distinguished from Moyamoya Syndrome (MMS). MMD is a primary disease process. MMS is a secondary process that occurs in response to another underlying pathological process that causes stenosis of intracranial blood vessels. There are two peaks of incidence with different clinical presentations, at around 10 years and 30-40 years. The peak appears to occur later in women than men. In children, ischemic symptoms, especially transient ischemic attacks, are predominant. Intellectual decline, seizures, and involuntary movements are also more common in this age group. In contrast, adult individuals present with intracranial hemorrhage more often than pediatric individuals.

Sickle Cell Disease (HD-21.6)

HD.ST.0021.6.A
v2.0.2026

- MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) is medically necessary for the following:
  - Screening to detect silent cerebral infarcts
  - New symptoms or cognitive impairment occurs or a change in academic performance
  - Prior to any change in therapy
- MRA Head (CPT® 70544, CPT® 70545 OR CPT® 70546) **OR** CTA Head (CPT® 70496) is medically necessary for the following:
  - Any new, indeterminate, or equivocal findings on MRI Brain
  - Prior to any change in therapy

Background and Supporting Information

Individuals with sickle cell disease are at significantly increased risk for stroke and silent infarction, beginning at a very young age. Recent advances allow physicians to identify individuals at high risk for stroke and begin a primary stroke prevention program.

Identification of silent cerebral infarction is important because treatment with prophylactic red cell transfusions to maintain hemoglobin S levels at <30% of total hemoglobin may reduce recurrent stroke and extent of neurologic damage.

- TCD for children aged 17 years old may be medically necessary on a case-by-case basis.
- See **Transcranial Doppler (CPT® 93886)(HD-24.8)** in the Head Imaging Guidelines for other indications for this modality and **Stroke/TIA (HD-21.1)** in the Head Imaging Guidelines.
- After 17 years old, for individuals with a history of abnormal TCDs, TCDs may be repeated every 3 months.
- TCD is not medically necessary for individuals with other phenotypes (Hgb SC, Hgb $S\beta^+$).

Multisystemic Smooth Muscle Syndrome (MSMS)/Smooth Muscle Dysfunction Syndrome (SMDS)/ACTA2 Mutations (HD-21.7)

HD.ST.0021.7.A
v2.0.2026

Indications	Medically Necessary Imaging
Initial evaluation for confirmed ACTA2 mutation	• MRI Brain without and with contrast (CPT® 70553) with OR without MRI perfusion **AND/OR** • MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **AND/OR** • MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549)
Repeat imaging if requested by neurologist and/or neurosurgeon and/or geneticist and/or provider coordinating care with a neurologist and/or neurosurgeon and/or geneticist	• MRI Brain without and with contrast (CPT® 70553) with OR without MRI perfusion **AND/OR** • MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **AND/OR** • MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549)

- MRI Perfusion may be obtained with MRI Brain (CPT® 70551 OR CPT® 70552 OR CPT® 70553)
  - No additional CPT® codes are medically necessary to perform MRI perfusion.
- Because radiation is a known risk factor for development of moyamoya, MRI/MRA Head is recommended instead of Computed Tomography (CT)/CTA.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - See *Background and Supporting Information*
- Conventional catheter angiogram 3D rendering (CPT® 76376 or CPT® 76377) should be reserved for individuals with focal neurologic symptoms or evidence on MRA or transcranial Doppler (TCD) of critical or progressive narrowing of the cerebral arteries.
  - See **Screening for Suspected Peripheral Artery Disease/Aneurysmal Disease (PVD-2)**

Background and Supporting Information

Smooth muscle dysfunction syndrome (SMDS)/Multisystemic Smooth Muscle Syndrome (MSMS) presents with a recognizable pattern of complications, including congenital mydriasis, patent ductus arteriosus (PDA), pulmonary arterial hypertension, aortic and other arterial aneurysms, moyamoya-like cerebrovascular disease, intestinal hypoperistalsis and malrotation, and hypotonic bladder.

SMDS/MSMS is caused by heterozygous mutations of the ACTA2 altering arginine 179, most commonly p.Arg179His. With a single exception, all cases are due to de novo mutations.

Cerebral Venous Sinus Thrombosis (HD-21.8)

HD.ST.0021.8.A
v2.0.2026

CT and MR Venography (CTV and MRV) are reported with the same codes as the CTA/MRA counterpart (there is no specific code for CT/MR venography):

- If arterial and venous CT or MR studies are both performed in the same session, only one CPT® code is used to report both procedures.
- If an arterial CTA or MRA study has been performed and subsequently a repeat study is needed to evaluate the venous anatomy, then this study is medically necessary.
- If a venous CTV or MRV study has been performed and subsequently a repeat study is needed to evaluate the arterial anatomy, then this study is medically necessary.

Indications	Medically Necessary Imaging
Venous vascular imaging for evaluation of venous infarcts	MR or CT Venography: • MRV Head (CPT® 70544, CPT® 70545, or CPT® 70546) **OR** • CTV Head (CPT® 70496)
Suspected cerebral venous thrombosis	• MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553) **OR** • CT Head without contrast CPT® 70450 **AND/OR** • MRV Head (CPT® 70544, CPT® 70545, or CPT® 70546) **OR** • CTV Head (CPT® 70496)
Follow up of known cerebral venous sinus thrombosis	• MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553) **OR** • CT Head without contrast (CPT® 70450) **AND/OR** • MRV Head (CPT® 70544, CPT® 70545, or CPT® 70546) **OR** • CTV Head (CPT® 70496)

Evidence Discussion (HD-21)

v2.0.2026

- Guidelines from the American Heart Association (AHA) and American Stroke Association supported the role of neuroimaging in stroke triage and individual selection for endovascular therapy in the management of acute stroke.[1,6,55] Current AHA guidelines also recommended non-invasive imaging of the carotid arteries for individuals with TIA or stroke who may be candidates for carotid endarterectomy or stenting.[1,6] This includes CT Angiography (CTA) of the head and neck or MR Angiography (MRA) of the head and neck.
- For clinically suspected stroke, initial imaging includes CT head to exclude intracranial hemorrhage, exclude other structural causes and assess for early ischemic changes.[1] CT Angiography (CTA) head is medically necessary during the initial evaluation to assess for large vessel occlusion and has high sensitivity of 93% and specificity of 100%.[1,54] CTA neck is also a rapid modality for imaging the extracranial vasculature to identify carotid stenosis, occlusion, and vertebral-basilar disease.[1]
- CT Perfusion (CTP) can identify individuals with large vessel occlusion who may be candidates for endovascular therapy in the acute stroke setting.
- A CT stroke protocol that includes unenhanced CT, CTA head, and CTP has effective radiation doses between 10-15 mSvm, with newer generation scanners and optimized sequences with lower radiation doses closer to 2 mSv.[5]
- MRI Brain with Diffusion Weighted Imaging (DWI) is the most sensitive test to detect an acute ischemic infarct, with a sensitivity of 94% and a specificity of 97%.[1,6,56,57]
- MR Angiography (MRA) Head and Neck is an alternative to CTA for identification of vascular lesions in the setting of a stroke evaluation.[1] Diagnostic cervicocerebral catheter angiography has the highest spatial and temporal resolution of any vascular imaging study, however, is invasive and requires use of contrast.[1]
- Compared with CT, a full stroke protocol with MRI is longer to acquire and susceptible to motion artifacts, in addition to contraindication with metallic devices, and certain implants.[55] MRI, however, does have the advantage of increased sensitivity for acute ischemia, including in transient ischemic attack, and does not require radiation.
- In the delayed stroke evaluation, CT Head may identify complications such as hemorrhagic conversion, mass effect and herniation.[55] MRI Brain in this scenario can confirm the extent of an ischemic stroke, evaluate for underlying pathology, and identify any complications.[55]
- For clinically suspected transient ischemic attack (TIA), CT Head is useful to exclude hemorrhage and other intracranial abnormalities.[1] CT perfusion can identify abnormalities in the setting of TIA in up to one-third of cases.[1] CT Angiography (CTA) Head and Neck is a rapid modality for evaluating intracranial and extracranial vascular lesions.[1] MRA Head and neck is an alternative modality, preferred in those

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

with renal impairment and iodine contrast allergy.[1] MRI Brain is the most sensitive modality for acute ischemic infarct.[1] MRI Brain with Diffusion Weighted Imaging (DWI) sequences can identify ischemic changes in approximately 40% of individuals with TIA.[58]

- For clinically suspected venous sinus thrombosis, imaging is medically necessary to identify the clot and assess for complications, such as venous infarction or hemorrhagic transformation. In addition to imaging previously reviewed for the stroke protocol, CT Venogram (CTV) or MR Venogram (MRV) are appropriate to localize the clot within the venous system.[1]
- For stroke or hemorrhage related to Cerebral amyloid angiopathy (CAA), Amyloid PET Brain has a sensitivity that ranges from 82% to 91%, however, its specificity is poor, ranging from 44% to 55%; therefore, this modality is not recommended.[33]

Cerebral Vasculitis (HD-22.1)

HD.CV.0022.1.A
v2.0.2026

- When CNS vasculitis is suspected, MRI Brain without and with contrast (CPT® 70553) is medically necessary
  - MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **AND/OR**
  - MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549); **OR**
  - CTA Head (CPT® 70496) **AND/OR**
  - CTA Neck (CPT® 70498) **OR**
  - CTA Head and Neck (CPT® 70471) if performed during the same session
  - The above studies are medically necessary concurrently with brain imaging
- Primary CNS vasculitis includes Giant Cell Arteritis also known as Temporal Arteritis (see **New Headache Onset Older than Age 50 (HD-11.7)**)
- If initial vascular imaging is suspicious for vasculitis, 3D rendering (CPT® 76377 or CPT® 76376) with cervicocerebral angiography/arteriography (see **General Guidelines- Other Imaging Situations (HD-1.7)**)
- Transcranial Doppler Studies for individuals with documented vasculitis or concern for vasospasm (see **Transcranial Doppler (CPT® 93886) (HD-24.8**))
- FDG-PET/CT Brain (CPT® 78608) is not supported due to lack of peer reviewed literature or expert consensus supporting the study for vasculitis.
- For extra-cranial giant cell arteritis evaluation (see **Giant Cell Arteritis (PVD-6.9.2))**

Background and Supporting Information

The diagnosis of primary central nervous system vasculitis is challenging because of its nonspecific and varied symptoms. Central nervous system vasculitis typically presents with headache, followed by encephalopathy and behavioral changes. Focal neurologic deficits, including but not limited to, visual loss, unilateral weakness, language impairment, sensory loss, incoordination, occurs in 20% to 30% of individuals. Seizures and intracranial hemorrhage may also occur. With a strong clinical suspicion, brain imaging is important for supporting the diagnostic process and directing biopsy.

Classification of vasculitides based on vessel size adapted from Younger. MRA and CTA are useful for the evaluation of the large proximal arteries; evaluation of a possible small vessel vasculitis may be beyond the resolution of routine MRA and CTA Head. However, other abnormalities, such as atherosclerotic disease, arterial dissection, Moyamoya disease, or reversible cerebral vasoconstriction may be demonstrated. Conventional angiogram is superior to MRA and CTA in demonstrating abnormalities in smaller vessels and is considered the "gold standard" in the evaluation of primary small vessel CNS vasculitis.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Dominant Vessel Involved	Primary	Secondary
Large arteries	• Giant cell arteritis • Takayasu's arteritis	Aortitis with rheumatoid disease; Infection (e.g., syphilis)
Medium arteries	• Classical polyarteritis nodosa • Kawasaki disease	Infection (e.g., hepatitis B)
Small vessels and medium arteries	• Wegener's granulomatosis • Churg–Strauss syndrome • Microscopic polyangiitis	Vasculitis with rheumatoid disease, systemic lupus erythematosus (lupus cerebritis), Sjögren's syndrome, drugs, infection (e.g., HIV)
Small vessels	• Henoch-Schönlein purpura • Essential cryoglobulinemia • Cutaneous leukocytoclastic vasculitis	Drugs (e.g., sulphonamides, etc.) Infection (e.g., hepatitis C)

Evidence Discussion (HD-22)

- Non-invasive neuroimaging modalities play a role in the diagnostic evaluation of central nervous vasculitis by providing supportive imaging findings and guiding biopsy.[3,6] The preferred modality for the evaluation of central nervous system vasculitis is MRI, which provides superior soft-tissue resolution.[6] MRI Brain is abnormal in >95% of individuals with CNS vasculitis.[8] MRI Brain shows infarcts in up to 50% of cases and white matter hyperintensities in 42% of cases.[3,6]
- MRA head was found to be abnormal in 81% of individuals with angiographic findings of vasculitis and normal in 100% of individuals with a normal angiogram.[6]
- CT Angiography is an alternative non-invasive modality that also provides visualization of blood vessels.[3,6,8]
- FDG-PET/CT brain is not supported due to the high physiologic FDG uptake in the brain and limited resolution of the camera system. Atherosclerosis may also interfere with the FDG-PET interpretation.

Indications	Medically Necessary Imaging
Stroke/TIA	See **Stroke/TIA (HD-21.1)**
Acoustic Neuroma/Vestibular Schwannoma	• MRI Brain without and with contrast (with IAC views) (CPT® 70553) **OR** without contrast (CPT® 70551) • Limited MRI of the internal auditory canals (CPT® 70540, CPT® 70542, OR CPT® 70543) when requested by the provider in place of a complete MRI Brain See also • **Acoustic Neuroma (HD-33.1)** • **Peripheral Nerve Sheath Tumors (PN-9.1)**
Head trauma/Temporal Bone Fracture/ Post-traumatic vertigo	• CT Head without contrast (CPT® 70450) ◦ See **Head Trauma (HD-13.1)** **AND/OR** • CT Orbit/Temporal bone without contrast (CPT® 70480)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indications	Medically Necessary Imaging
Vertebrobasilar disease/ Vertebrobasilar Insufficiency/ Dissection	• CTA Head (CPT® 70496 **AND/OR** • CTA Neck (CPT® 70498) **OR** • CTA Head and Neck (CPT® 70471) if performed during the same session **OR** • MRA Head (CPT® 70544, CPT® 70545, OR CPT® 70546) **AND/OR** • MRA Neck (CPT® 70547, CPT® 70548, or CPT®70549) See also: • **General Guidelines - CT and MR Angiography (CTA/ CTV and MRA/MRV) (HD-1.5)** • **Headache and Suspected Vascular Dissection (HD-11.1)** • **Intracranial Cerebral Aneurysms (HD-12.1)**
Semicircular canal dehiscence	• CT Orbit/Temporal bone without contrast (CPT® 70480)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indications	Medically Necessary Imaging
Meniere's Disease	• MRI Brain without and with contrast (with IAC views) (CPT® 70553) **OR** without contrast (CPT® 70551) • Limited MRI of the internal auditory canals (CPT® 70540, CPT® 70542, OR CPT® 70543) when requested by the provider in place of a complete MRI Brain

Background and Supporting Information

- Dizziness, a common complaint, with benign and dangerous causes, may be continuous, triggered, or spontaneous.
- For the continuously dizzy individual with nystagmus at the time of evaluation, a head impulse test and a test of skew should be performed to determine if dizziness is due to a peripheral cause or a posterior circulation stroke. Abnormalities on exam may be indications for imaging as detailed in the guideline.
- For triggered dizziness, positional testing such as the Dix-Hallpike maneuver, and/or orthostatic blood pressure measurements, should be performed. If symptoms are reproduced on examination, triggered dizziness is confirmed.
- Spontaneous dizziness may be due to vestibular migraine, TIA, or Meniere's disease, among other causes. A detailed neurologic examination should be performed, and imaging as detailed in the guideline.
- The Dix-Hallpike maneuver should be performed or the individual should be referred to a clinician who could perform the procedure if Benign Paroxysmal Positional Vertigo (BPPV) is suspected.
- The Head Impulse Test (HIT) is also known as the Head thrust test. It is designed to evaluate the vestibular-ocular reflex in an individual with concern for a peripheral vestibulopathy due to ACUTE spontaneous vertigo. The individual is instructed to look at the examiner during the entire test. The individual's head is then quickly turned or rotated to one side and then the other. If normal, the individual's eyes should remain locked on the examiner. If abnormal, the eyes will move in the direction of the head rotation and then quickly correct. This saccade indicates peripheral vestibular hypofunction on the side of the direction that the head is turned. The HIT test is

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

abnormal in individuals with vestibular neuronitis, and normal in individuals with a posterior circulation stroke.

- Posterior Canal BPPV (85%-95% of BPPV cases) is defined as:
  - Individual reports repeated episodes of vertigo with changes in head position relative to gravity.
  - Each of the following criteria is fulfilled on physical exam:
    - Vertigo associated with torsional (rotatory), upbeating (toward the forehead) nystagmus is provoked by the Dix-Hallpike test.
    - There is a latency period between the completion of the Dix-Hallpike maneuver and the onset of vertigo and nystagmus.
    - The provoked vertigo and nystagmus increase and then resolve within 60 seconds from the onset of the nystagmus.
- Lateral or Horizontal Canal BPPV (5%-15% of BPPV cases) will have horizontal or no nystagmus to which a supine roll test assesses for this condition.
- Exclusions for Dix-Hallpike maneuver
  - Individual previously diagnosed with BPPV and who on date of encounter in calendar year does not have positional dizziness or vertigo consistent with active BPPV
  - Individual has declined Dix-Hallpike maneuver
  - Individual has cervical spinal disease (i.e., cervical stenosis, severe kyphoscoliosis, limited cervical range of motion, Down's syndrome, severe rheumatoid arthritis, cervical radiculopathies, Paget's disease, ankylosing spondylitis, low back dysfunction, spinal cord injuries, spinal fractures)
  - Individual unable to lay flat (i.e., severe heart disease)
  - Individual has severe atherosclerotic disease or recent dissection involving the anterior or posterior cerebral circulation
  - Unable to be seated in exam chair (i.e., morbidly obese), or maneuver cannot be safely performed given morbid obesity
  - Ehlers Danlos/Marfans/Connective tissue disorder due to risk of cranio spinal instability/dissection
- Triggered episodic vestibular syndrome (t-EVS) usually last seconds to minutes with the most common triggers (vs. exacerbating factors) are head motion or change in body position. In the Emergency Department, benign paroxysmal positional vertigo (BPPV) is the second most common cause of t-EVS after orthostatic hypotension. Far lateral rotation of the neck leads to mechanical occlusion of one or both vertebral arteries causing temporary symptoms of vertigo and nystagmus when this position is maintained and may occur with the individual upright.
- Diagnoses or conditions associated with orthostatic hypotension (OH) or nOH include: Parkinson Disease (PD), Multiple System Atrophy (MSA), Pure Autonomic

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Failure (PAF) or Dementia with Lewy Bodies (DLB), unexplained fall or syncope, peripheral neuropathies secondary to diabetes, amyloidosis and HIV), individuals ≥70 years of age and frail and on multiple medications and individuals with postural (orthostatic) dizziness or nonspecific symptoms that occur when standing. Symptoms may include: lightheadedness or dizziness, the sensation of blacking out, cognitive dysfunction, mental dulling, generalized weakness, neck pain or discomfort in the suboccipital and paracervical region (coat hanger) or platypnea (dyspnea while standing).

- Secondary or advanced laboratory testing is considered for use in select individuals for paraneoplastic syndromes (paraneoplastic panel) and serum and urine protein electrophoresis for monoclonal gammopathy for peripheral neuropathy.
  - See **Polyneuropathy (PN-3.1)** in the Peripheral Nerve and Neuromuscular Disorders Imaging Guidelines, **Multiple Myeloma and Plasmacytomas (ONC-25)** in the Oncology Imaging Guidelines, and **Paraneoplastic Syndromes (ONC-30.3)** in the Oncology Imaging Guidelines.
- Semicircular canal dehiscence (SCD) is a rare syndrome caused by dehiscence in the boney covering of the affected superior, posterior or lateral semicircular canal. When present, it can result in vestibular symptoms of vertigo associated with auditory symptoms including oscillopsia evoked by noise and conductive hearing loss. The vestibular symptoms in SCD can be debilitating. Individuals may note that loud noises cause them to see things moving or that they experience a similar sensation when they cough, sneeze, or strain to lift something heavy. The signs of vestibular abnormalities in SCD relate directly to the effect of the dehiscence which has created a third mobile window of the inner ear. Some individuals have a conductive hearing loss for low-frequency sounds that can resemble the pattern in otosclerosis.
- Occlusive carotid artery disease does not cause fainting but rather causes focal neurologic deficits such as unilateral weakness. Thus, carotid imaging will not identify the cause of the fainting and increases cost. Fainting is a frequent complaint, affecting 40% of people during their lifetime.

Evidence Discussion (HD-23.1)

- MRI Brain is the preferred initial imaging modality for evaluation of persistent vertigo, vertigo associated with an abnormal neurologic exam, and vertigo due to a suspected central cause. [24,25]
- CT Head is not recommended for the initial evaluation of dizziness due to inferior soft tissue resolution when compared to MRI Brain. In addition, MRI Brain provides better visualization of the cerebellum and posterior fossa and is more sensitive for the detection of posterior fossa infarcts. For suspected superior semicircular canal dehiscence, CT Temporal bone is the appropriate initial imaging study.[24]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- In the evaluation of dizziness or vertigo in the emergency department, the positivity rate of CT Head was 2%, for MRI Brain 4%, with the diagnostic yield increasing to 12% for MRI Brain if neurologic findings were present.[24]
- For dizziness due to suspected vertebral-basilar insufficiency, MRA sensitivity reaches 97% when performed with contrast-enhancement.[24]
- For suspected vertebral artery dissection, CTA had the highest sensitivity 100%, followed by MRA 77%, and Doppler ultrasound at 71%.[24]
- Vascular imaging should include the entire vertebral artery from the origin at the aortic arch to the basilar artery.[24]

Syncope (HD-23.2)

HD.DZ.0023.2.A
v2.0.2026

Indications	Medically Necessary Imaging
Syncope with focal signs of a neurologic deficit **OR** Syncope without focal signs of a neurological deficit AND negative or inconclusive Electrocardiogram (EKG)	• MRI Brain without contrast (CPT® 70551) **OR** • MRI Brain without and with contrast (CPT® 70553) **OR** • CT Head without contrast (CPT® 70450) **AND/OR** • CTA Head (CPT® 70496) **OR** • MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) **AND/OR** • CTA Neck (CPT® 70498) **OR** • MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) ◦ CTA Head and Neck (CPT® 70471) must be substituted if performed during the same session
Recurrent syncope with risk of head injury or head trauma related to syncope	See **Head Trauma (HD-13.1)**
Situational syncope, including precipitating factors to syncope such as coughing, defecation, eating, laughing, or urination Myoclonic jerks without symptoms or signs associated with seizure, including but not limited to prolonged amnesia/confusion, tongue biting.	Advanced imaging is not medically necessary

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indications	Medically Necessary Imaging
Loss of consciousness with other symptoms or signs of seizure, including but not limited to, prolonged amnesia/ confusion, tongue biting, and/or urinary incontinence.	See **Epilepsy/Seizure (HD-9.1)**

Evidence Discussion (HD-23.2)

- The Choosing Wisely Campaign Best Practices, supported by the American College of Emergency Physicians, American College of Physicians, and the American Academy of Neurology recommended against neuroimaging in the evaluation of simple syncope and a normal neurologic evaluation.[1,15]
- The initial evaluation for individuals with syncope includes a detailed history, physical exam, and electrocardiography.[1,6,15,26,29] Neuroimaging has a low diagnostic yield of 5% to 6.4% of an acute abnormality on CT Head.[1,15,27] Clinical factors associated with abnormal scans include head trauma or a focal neurologic deficit on exam.[1,15,27]
- In select cases when neuroimaging is medically necessary, structural brain imaging with either CT Head or MRI Brain may be useful, along with vascular imaging, depending on the suspected underlying pathology.[15,29]
- Inappropriate imaging studies may identify incidental findings, incorrectly assumed to be the cause of syncope, leading to further delay in the identification of the true cause and risk additional unnecessary procedures.[26]
- Situational syncope does not require advanced imaging.[3,6,28]

Transcranial Magnetic Stimulation (TMS) (HD-24.1)

HD.OI.0024.1.A
v2.0.2026

In TMS, an electromagnetic coil placed on the surface of the skull overlying the motor cortex depolarizes the motor axons, creating a motor evoked potential (MEP), which is recorded via superficial skin electrodes as it passes through the upper and lower motor pathways to an innervated muscle.

TMS is typically utilized for behavioral health purposes.

Functional MRI (fMRI) (HD-24.2)

HD.OI.0024.2.A

v2.0.2026

- fMRI is useful in pre-operative scenarios to define the “eloquent” areas of brain
  - The ordering physician must be a neurologist, neurosurgeon or radiation oncologist or any provider in consultation with one of these specialists.
- Primary medically necessary indications for fMRI include, but are not limited to, the following:
  - Assessment of intracranial neoplasm and other targeted lesions
  - Pre-surgical planning and operative risk assessment
  - Assessment of eloquent cortex (e.g., language, sensory, motor, visual centers) in relation to a tumor or another focal lesion
  - Surgical planning (biopsy or resection)
  - Therapeutic follow-up, as a one-time, post-operative, follow- up study
  - Evaluation of preserved eloquent cortex
  - Assessment of eloquent cortex for epilepsy surgery
  - Assessment of radiation treatment planning and post-treatment evaluation of eloquent cortex
- fMRI is medically necessary with PET Brain in epilepsy surgery planning
- Procedure codes for functional MRI:
  - CPT® 70554 MRI Brain, functional MRI, including test selection and administration of repetitive body part movement and/or visual stimulation, not requiring physician or psychologist administration
  - CPT® 70555 MRI Brain, functional MRI; requiring physician or psychologist administration of entire neurofunctional testing
  - If MRA Head (CPT® 70544) is medically necessary but Functional MRI (CPT® 70554 or CPT® 70555) was erroneously ordered, then CPT® 70544 may be substituted when appropriate
- MRI Brain (CPT® 70551 or CPT® 70553) and/or fMRI (CPT® 70554 or CPT® 70555) are medically necessary concurrently
  - See **Unlisted Procedures/Therapy Treatment Planning (Preface-4.3)** in the Preface Imaging Guidelines if MRI Unlisted is requested for surgical planning

Magnetic Resonance Spectroscopy (MRS) (HD-24.3)

HD.OI.0024.3.A
v2.0.2026

- MRS (CPT® 76390) involves analysis of the levels of certain chemicals in a pre-selected voxels (small regions) on an MRI scan done at the same time.
- When conventional imaging by magnetic resonance imaging (MRI) or computed tomography (CT) provides limited information regarding specific clinical questions, indications for MRS in adults and children include, but are not limited to, the following and are evaluated on a case-by-case basis:
  - Distinguish recurrent brain tumor from radiation necrosis as an alternative to PET (CPT® 78608)
  - Diagnosis of certain rare inborn errors of metabolism affecting the CNS (primarily pediatric individuals)
  - Evidence or suspicion of primary or secondary neoplasm (pre-treatment and post-treatment)
  - Grading of primary glial neoplasm, particularly high-grade versus low-grade glioma
  - Evidence or suspicion of brain infection, especially cerebral abscess (pre-treatment and post-treatment) and HIV-related infections
  - Seizures, especially temporal lobe epilepsy

Background and Supporting Information

- Evaluation of certain primary brain tumors where diagnostic accuracy has been established in peer-reviewed literature.
  - See **Primary Central Nervous System Tumors – General Considerations (ONC-2.1)**, **Low Grade Gliomas (ONC-2.2)**, and **High Grade Gliomas (ONC-2.3)** in the Oncology Imaging Guidelines

CSF Flow Imaging (HD-24.4)

HD.OI.0024.4.A

v2.0.2026

- Pulse-gated MRI imaging or MRI CINE is generally performed as a part of an MRI Brain study. It is not coded separately for pre-operative evaluation of hydrocephalus, Chiari syndromes, Normal Pressure Hydrocephalus, Idiopathic Intracranial Hypertension (also known as pseudotumor cerebri), and spontaneous intracranial hypotension.
- There is no specific or unique procedure code for this study; it is done as a special sequence of a routine MRI Brain without contrast (CPT® 70551).
- If not previously performed as part of recent study, a second study for the purpose of evaluating CSF flow is medically necessary.

CT or MRI Perfusion (HD-24.5)

HD.OI.0024.5.A
v2.0.2026

- Performed as part of a CT Head or MRI Brain examination in the evaluation of individuals with very new strokes or brain tumors.
- CT perfusion study is coded as either CPT® 70472 or CPT® 70473
- CPT® 70472, CT cerebral perfusion analysis with contrast material, including imaging postprocessing, performed with concurrent CT or CT angiography of the same anatomy, (use in conjunction with 70450, 70460, 70470, 70471, 70496).
