- CPT® 70472 or 70473 - “cerebral perfusion analysis using CT” is medically necessary for the following:
  - Evaluation of acute stroke (<24 hours) to help identify individuals with stroke-like symptoms and to help identify those most likely to benefit from thrombolysis or thrombectomy
  - Follow-up for acute cerebral ischemia or infarction and/or reperfusion in the subacute or chronic phase of recovery
  - To assist in planning and evaluating the effectiveness of therapy for cervical or intracranial arterial occlusive disease (as an isolated test or in combination with a cerebrovascular reserve challenge) and/or chronic cerebral ischemia
  - Identifying cerebral hyperperfusion syndrome following revascularization
  - Evaluation of the vascular status of solid tumors where MRI is degraded due to susceptibility artifact from air-containing spaces, surgical clips, or dental work
  - Follow-up of tumor response to therapy
- MRI Perfusion is obtained with MRI Brain (CPT® 70551 OR CPT® 70552 OR CPT® 70553).
  - No additional CPT® codes are medically necessary to perform MRI perfusion.
- Medically necessary indications for perfusion magnetic resonance imaging (MRI) MRI Perfusion (CPT® 70551 OR CPT® 70552 OR CPT® 70553)[9] include the following:
  - Diagnosis and Characterization of Mass Lesions
    - Differential diagnosis (tumor versus tumor mimic)
    - Diagnosis of primary neoplasms (may include grading)
    - Surgical planning (biopsy or resection)
    - Targeting locations for biopsy
    - Guiding resection extent

Click Here to Return to the Main TOC

- Therapeutic follow-up
  - Radiation necrosis versus recurrent or residual tumor
  - Chemonecrosis versus recurrent or residual tumor
  - Pseudoprogression and pseudoresponse
  - Monitor potential transformation of non-resectable low-grade neoplasms to higher grade
- Assessment of Neurovascular Disease
  - Acute stroke (assessment of ischemic penumbra)
  - Assessment of the hemodynamic significance of cervical or intracranial vascular stenosis
  - Assessment of cervical or intracranial revascularization efficacy
  - Assessment of vasospasm

• Other indications are usually regarded as not medically necessary.

Cone Beam Computed Tomography (CBCT) (HD-24.7)

HD.OI.0024.7.A

v2.0.2026

- CPT® Codes: CPT® 70486, CPT® 70487, CPT® 70488, CPT® 70480, CPT® 70482 (No separate 3-D rendering codes should be reported)
- An alternative to traditional CT imaging is in-office cone beam testing and possible decreased radiation dosage. The indications for office-based CT imaging are the same as for traditional scanners, and they should not be used for diagnosing or managing uncomplicated acute bacterial rhinosinusitis (ABRS).
- See **Temporomandibular Joint Disease (TMJ) (HD-30.1)** and **Dental/Periodontal/ Maxillofacial Imaging (HD-30.2)**

Transcranial Doppler (CPT® 93886) (HD-24.8)

HD.OI.0024.8.A
v2.0.2026

- Transcranial Doppler (TCD) is a non-invasive ultrasonic technique that measures local blood flow velocity and direction in the proximal portions of intracranial and extracranial arteries

CPT Code	Description	Additional Notes
93886	Transcranial Doppler study of the intracranial arteries; complete study	
93888	Transcranial Doppler study of the intracranial arteries; limited study	
93892	Transcranial Doppler study of the intracranial arteries; emboli detection without intravenous microbubble injection	
93893	Transcranial Doppler study of the intracranial arteries; venous-arterial detection with intravenous microbubble injection	Report 93893 if the study is performed with intravenous microbubble injection. Transcranial Doppler studies described as “with contrast” are performed with intravenous microbubble injection. The bubbles serve to enhance ultrasound thus enabling better visualization of the intracranial arteries.

- Transcranial Doppler studies are ordered either as a single complete or limited study or as a combination of the complete or limited study with additional studies for further evaluation of the condition being investigated.
- Evaluation of Stroke/TIA usually includes CPT® 93886 (Vasoreactivity study) and either CPT® 93892 or CPT® 93893 (Emboli detection).

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Examples include:
    - Evaluation of right to left cardiac shunts: Detection of microemboli in individuals with stroke or TIA. (CPT® 93892 or CPT® 93893 added to CPT® 93886)
    - Evaluation of intracranial occlusive disease in individuals with documented stroke or TIA
    - Evaluation of hemodynamic effects of known severe extra-cranial occlusive disease
- TCD studies are medically necessary for the following:
  - Evaluation of severe stenosis or occlusion of the extracranial (≥60% diameter reduction) and major basal intracranial arteries (≥50% diameter reduction)
  - Detection and serial evaluation of cerebral vasospasm in subarachnoid hemorrhage
  - Evaluation of cerebral embolization including in COVID-19 and refractory encephalopathy
  - Assessing the extent of collateral circulation in individuals with known regions of severe stenosis or occlusion
  - To detect residual right to left shunting after repair/closure of an intracardiac or intrapulmonary shunt
  - Evaluation of AVM both pre- and post-surgical intervention.
  - Periprocedural monitoring to detect cerebral thrombosis, embolization, hypoperfusion, and hyperperfusion
  - Assessing the stroke risk in children aged two to sixteen with homozygous sickle cell disease
  - Annual screening for individuals with Sickle Cell Anemia (Hb-SS) and Sickle Beta Thalassemia (Sß) (CPT® 93886) up to the age of 16.
- TCD studies are not medically necessary for evaluation of:
  - Brain tumors
  - Familial and degenerative disease of the brain
  - Psychiatric disorders
  - Epilepsy
  - Migraine or other primary headache disorders
  - Infectious and inflammatory conditions

Background and Supporting Information

- Transcranial Doppler (TCD) ultrasound provides rapid, non-invasive, real-time measure of cerebrovascular function.
- TCD can be used to measure flow velocity in the proximal cerebral arteries to assess relative changes in flow, diagnose focal vascular stenosis, or to detect embolic signals within these arteries.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- TCD can be used to measure blood flow responses to changes in blood pressure (cerebral autoregulation), changes in end-tidal CO2 (cerebral vasoreactivity), or cognitive and motor activation (neurovascular coupling or functional hyperemia).
- A technical limitation of TCD includes inadequate temporal bone acoustic windows due to a thickened skull which limits ultrasound penetration.
- Studies are ongoing regarding the use of TCD in the evaluation of dementia and psychiatric conditions such as depression.
- CPT® 93892 and CPT® 93893 represent add on services that require additional expertise, lab time, and equipment not included in the complete and limited codes. These additional codes may be appropriate during the same encounter if medical necessity is documented.
- CPT® 93892/CPT® 93893: Identification of right to left shunts (microembolic signals may be detected during TCD monitoring) and may indicate source of emboli in individuals with stroke or TIA. TCD bubble test is very sensitive and may be superior to transthoracic and transesophageal echocardiography in detection of right to left shunts.
- Transcranial Doppler (TCD) is considered not medically necessary for the following indications:
  - Assessing individuals with migraine;
  - Monitoring during cardiopulmonary bypass and other cerebrovascular and cardiovascular interventions, and surgical procedures (except during carotid endarterectomy, as noted above);
  - Evaluation of individuals with dilated vasculopathies such as fusiform aneurysms;
  - Assessing autoregulation, physiologic, and pharmacological responses of cerebral arteries; and/or
  - Evaluating children with various vasculopathies, such as moyamoya disease and neurofibromatosis.

Evidence Discussion (HD-24)

v2.0.2026

- Functional magnetic resonance imaging (fMRI) is useful for localizing eloquent cortex in relation to a focal brain lesion, for pre-surgical planning and therapeutic follow up.[7] Overall functional MRI imaging sensitivity is 83% with a specificity of 82%, for mapping language and motor functions. [22] Functional MRI is a useful tool for predicting post-operative outcomes in individuals with a single brain tumor.[23] Overall, fMRI studies are used in pre-operative decision making in 89% of tumor individuals and in 91% of epilepsy surgery individuals.[24,25] In 63% of epilepsy individuals undergoing surgical evaluation, fMRI imaging results helped to avoid further studies, including the Wada test.[25]
- For cases when conventional imaging by magnetic resonance imaging or computed tomography provides limited information regarding specific clinical questions, magnetic resonance spectroscopy (MRS) provides further characterization of brain tumors, radiation treatment changes, cerebral abscess, seizure disorders, and inherited metabolic disorders.[8,27,28] MRS has a 90% sensitivity and 86% specificity in distinguishing tumoral tissue from non-tumoral tissue.[27]
- Pulse-gated MRI imaging or MRI CINE is performed as part of an MRI Brain study and allows qualitative and quantitative analysis of oscillatory cerebrospinal fluid (CSF) movement in normal and abnormal conditions.[11,21] This imaging technique is useful for evaluation of hydrocephalus, Chiari syndromes, Normal Pressure Hydrocephalus, intracranial hypertension, and spontaneous intracranial hypotension.[10,11]
- MRI perfusion is useful for the diagnosis and characterization of mass lesions, surgical planning and therapeutic follow-up.[9,30] MR perfusion allows localization of tumor for higher yield on stereotactic biopsy and non-invasive differentiation between radiation necrosis from recurrent tumor when conventional MR findings are equivocal.[30]
- CT perfusion has multiple uses including in stroke diagnosis and treatment planning, characterization of neoplastic disease and response to treatment, and is alternative modality for those with contraindication to MRI-based perfusion imaging.[2,29]
- The American Heart Association/American Stroke Association guidelines for acute stroke management recommended CT Perfusion for selecting candidates for mechanical thrombectomy within 24 hours after last known well.[29]

Epistaxis (HD-25.1)

HD.EX.0025.1.A
v2.0.2026

- After initial nasal endoscopy by ENT, if there are findings suspicious for a mass lesion, the following imaging is medically necessary:
  - CT Maxillofacial without or with contrast (CPT® 70486 or CPT® 70487) **AND/OR**
  - MRI Orbit/Face/Neck without and with contrast (CPT® 70543)
- Individuals who have failed initial management with cauterization and packing and have persistent or recurrent epistaxis despite these primary interventions, should be referred to a clinician who can evaluate the individual for their candidacy for surgical ligation or endovascular embolization.
- Prior to embolization with surgical or endovascular technique, CT Maxillofacial without contrast (CPT® 70486) **OR** CT Maxillofacial with contrast (CPT® 70487) is medically necessary when requested by the clinician performing embolization or referring for embolization.
  - If endovascular embolization is planned, the following studies are medically necessary ahead of the interventional radiologic procedure:
    - CTA Head (CPT® 70496) OR
    - CTA Neck (CPT® 70498)
      - CTA Head and Neck (CPT® 70471) must be substituted if performed during the same session.

Background and Supporting Information

The American Academy of Otolaryngology Head and Neck Surgery recommended, in its most recent 2020 Clinical Practice Guidelines on Epistaxis, that the clinician should perform, or should refer to a clinician who can perform, nasal endoscopy to identify the site of bleeding and guide further management in individuals with recurrent nasal bleeding, despite prior treatment with packing or cautery, or with recurrent unilateral nasal bleeding. No recommendations for advanced imaging are outlined in this guideline without the exam findings (anterior rhinoscopy and/or nasal endoscopy) or the procedural needs of the individual indicating the need for such studies. If anterior rhinoscopy does not reveal the source of bleeding, it is recommended that the clinician perform nasal endoscopy or refer to a clinician who can perform nasal endoscopy, first.

Embolization procedures have shown an average nosebleed control rate of 87%, with minor transient complications in 20% (transient nasal ischemia, temporal-facial pain or numbness, headache, swelling, jaw claudication, trismus, and access site complications not requiring additional therapy) and major complications in up to 2.1% to 3.8% (skin/nasal necrosis, permanent facial nerve paralysis, monocular blindness, and stroke).

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Detailed angiography, including internal and external carotid angiography, and precise embolization techniques are required. Despite use of meticulous techniques and knowledge of external carotid-internal carotid anastomoses, blindness and stroke are the most feared complications of endovascular embolization. These complications are rare but are more frequent than in individuals undergoing surgical arterial ligation. In one study, similar transient ischemic attacks are demonstrated across all groups but there is increased risk of stroke in the groups who underwent endovascular embolization alone (0.9%) or combined with surgical ligation (1.6%) as compared with surgical ligation alone (0.1%).

Evidence Discussion (HD-25)

- The American Academy of Otolaryngology - Head & Neck Surgery (AAO-HNS) recommendeds, in its most recent 2020 Clinical Practice Guidelines on Epistaxis, that the clinician should perform, or should refer to a clinician who can perform, nasal endoscopy to identify the site of bleeding and to guide further management in individuals with recurrent nasal bleeding despite prior treatment with packing or cautery, or with recurrent unilateral nasal bleeding. No recommendations for advanced imaging are outlined in this AAO-HNS Guideline without the exam findings (anterior rhinoscopy and/or nasal endoscopy) or the procedural needs of the individual, directing the need for such studies. If anterior rhinoscopy does not reveal the source of bleeding, it is recommended that the clinician perform nasal endoscopy or refer to a clinician who can perform nasal endoscopy.[3]
- Further characterization of any mass lesions suspected on initial nasal endoscopy may be evaluated with CT Maxillofacial, either with OR without contrast (CPT® 70487 or CPT® 70486), AND/OR MRI Orbit, Face, and/or Neck without and with contrast (CPT® 70543).[1,2]
- Because of the risks involved in embolization procedures (blindness, stroke, and others), CT or MRI imaging is supported prior to any planned intervention.[4]
- Embolization procedures have shown an average nosebleed control rate of 87%, with minor transient complications in 20% (transient nasal ischemia, temporal-facial pain or numbness, headache, swelling, jaw claudication, trismus, and access site complications not requiring additional therapy) and major complications in up to 2.1% to 3.8% (skin/nasal necrosis, permanent facial nerve paralysis, monocular blindness, and stroke).[4,5]

Mastoid Disease or Ear Pain (HD-26.1)

HD.MA.026.1.A
v2.0.2026

A pertinent clinical evaluation including a detailed history, physical examination (including otoscopic examination), must be performed on any individual with ear pain prior to considering advanced imaging. Common causes of ear pain include external and middle ear infections, dental problems, sinus infection, neck problems, tonsillitis, and pharyngitis.

Indications (Any one of the following)	Medically Necessary Imaging
• Persistent ear pain without obvious cause • Clinical suspicion for complicated or invasive infection such as mastoiditis • Clinical suspicion for complications from otitis media • Clinical suspicion of mass lesion causing ear pain • Significant trauma with concern for hematoma formation • Pre-operative planning • (For additional imaging requirements for cholesteatoma surgery, see bullet below) • (For skull base osteomyelitis, see **Skull Base Osteomyelitis (SBO) (HD-20.2)**)	• CT Orbits/Temporal Bone without contrast (CPT® 70480) **OR** • CT Orbits/Temporal Bone without and with contrast (CPT® 70482) **OR** • MRI Brain without and with contrast with attention to internal auditory canals (CPT® 70553) **OR** • MRI Orbits/Face/Neck without and with contrast (CPT® 70543)

- Advanced imaging is not medically necessary in the overwhelming majority of individuals with ear pain.
- The following imaging is medically necessary for **pre-operative evaluation** for cholesteatoma surgery when ordered by an otolaryngologist or in consultation with the otolaryngologist:
  - CT Orbits/Temporal Bone without contrast (CPT® 70480) **OR**
  - CT Orbits/Temporal Bone without and with contrast (CPT® 70482)

    AND/OR
  - MRI Brain without and with contrast with attention to internal auditory canals (CPT® 70553) **OR**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - MRI Internal Auditory Canal: (IAC) MRI can be reported as a limited study with one code from the set (CPT® 70540, CPT® 70542, or CPT® 70543), but should not be used in conjunction with MRI Brain codes (CPT® 70551, CPT® 70552, or CPT® 70553) if IAC views are performed as part of the brain
- The following imaging is medically necessary one time **post-operatively** to exclude residual or regrown cholesteatoma to avoid the need for a second-look surgery when ordered by an otolaryngologist or in consultation with the otolaryngologist:
  - CT Orbits/Temporal Bone without contrast (CPT® 70480) **AND/OR**
  - MRI Brain without and with contrast with attention to internal auditory canals (CPT® 70553), **OR**
  - MRI Internal Auditory Canal: (IAC) MRI can be reported as a limited study with one code from the set (CPT® 70540, CPT® 70542, or CPT® 70543), but should not be used in conjunction with MRI Brain codes (CPT® 70551, CPT® 70552, or CPT® 70553 if IAC views are performed as part of the brain
- Eustachian Tube Dilation: (endoscopic balloon dilatation of the Eustachian Tube, to treat persistent Eustachian tube dysfunction)
  - CT Orbit/Temporal Bone without contrast (CPT® 70480) is medically necessary for pre-operative evaluation of possible aberrant carotid.
- Concern for petrous apex lesions when requested by the otolaryngologist or in consultation with the otolaryngologist, the following are medically necessary:
  - CT Orbit/Temporal bone without contrast (CPT® 70480) **OR**
  - CT Orbit/Temporal bone without and with contrast (CPT® 70482) **AND/OR**
  - MRI Brain without and with contrast (CPT® 70553) **OR**
  - MRI Internal Auditory Canal: (IAC) MRI can be reported as a limited study with one code from the set (CPT® 70540, CPT® 70542, or CPT® 70543), but should not be used in conjunction with MRI Brain codes (CPT® 70551, CPT® 70552, or CPT® 70553 if IAC views are performed as part of the brain
- For concern related to non-resolving otalgia with chronic otorrhea:
  - See **Skull Base Osteomyelitis (SBO) (HD-20.2)**

Background and Supporting Information

- Common causes of ear pain include external and middle ear infections, dental problems, sinus infection, neck problems, and referred pain from the oral pharynx.
- Clinical suspicion for complications from otitis media such as coalescent mastoiditis, resulting in: subperiosteal abscess formation/Bezold's abscess, acute facial nerve paralysis, and intracranial abscess formation.
- Cholesteatomas are expansive cysts of the middle ear filled with cellular debris. They can be congenital or arise from recurrent middle ear infections or trauma to the tympanic membrane. Hearing loss is usually conductive, although if the lesion is

Copyright ©2026 United HealthCare Services, Inc.

large enough combined conductive and sensorineural hearing loss may be present. Otoscopic exam findings and symptoms may include a white mass in the middle ear cleft, painless drainage from the ear or chronic/recurrent ear infections.

- Petrous apex lesions/infections may include: cholesteatoma, cephalocele, mucocele, and cholesterol granuloma and can present with symptoms of pain, hearing loss, headache, vertigo, and Cranial nerve insults (including CN V VI, VII, IX, X, XI).

Evidence Discussion (HD-26)

- Contrast enhanced CT is commonly used for evaluation of head and neck infections due to its accessibility and short examination time. MRI provides better sensitivity of soft tissue infections in the setting of cholesteatoma, when there is concern for abscess formation or intracranial complications.[7]

Hearing Loss (HD-27.1)

HD.HL.0027.1.A
v2.0.2026

- An initial evaluation including hearing tests, by bedside testing or by formal audiology, is necessary to determine whether an individual's hearing loss is conductive (external or middle ear structures) or sensorineural (inner ear structures, such as cochlea or auditory nerve) hearing loss. See **General Guidelines (HD-1.0)**
- CT Orbits/Temporal Bone without (CPT® 70480) **OR** MRI Brain without and with contrast (with IAC views) (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551) is medically necessary for the following:
  - Mixed conductive (MC)/Sensorineural (SN) hearing loss or any sensorineural hearing loss (MRI generally preferred for SN - See *Background and Supporting Information*)
  - Unilateral fluctuating or asymmetric hearing loss
  - Cholesteatoma (see **Mastoid Disease or Ear Pain (HD-26.1)**)
  - Congenital hearing loss
  - Surgical planning, including cochlear implants (both CT Temporal Bone and MRI Brain for surgical planning if requested by surgeon or any provider in consultation with the surgeon)
  - Hearing loss with vertigo (see **Dizziness/Vertigo (HD-23.1)**)
- CT Orbits/Temporal Bone without contrast (CPT® 70480) is medically necessary for the following:
  - Conductive hearing loss should have a CT Temporal Bone initially in the absence of an evident mass in the middle ear
- CT Orbits/Temporal Bone with contrast (CPT® 70481) is medically necessary for the following:
  - Glomus tumors or other vascular tumors of the middle ear, and/or surgical planning
  - Acquired sensorineural hearing loss if MRI unavailable or contraindicated
- Limited MRI of the internal auditory canals (CPT® 70540, CPT® 70542, or CPT® 70543) is medically necessary when requested by the provider in place of a complete MRI Brain. Note: Limited MRI codes should not be used in addition to MRI Brain codes; IAC views are performed as additional sequences as part of the brain study (see **General Guidelines – Anatomic Issues (HD-1.1)**)
- FIESTA protocol can be performed with MRI Brain without contrast (CPT® 70551) or limited MRI with attention to internal auditory canals.

Background and Supporting Information

- Sensorineural (SN) hearing loss – MRI is generally preferable to CT. CT Temporal bone is medically necessary in post-traumatic SN hearing loss, to evaluate for bony

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

remodeling of the IAC due to vestibular schwannoma and labyrinthine ossification resulting from prior infection and for consideration of otospongiosis, a common cause of MC and SN hearing loss.

Evidence Discussion (HD-27.1)

- A complete history and otologic exam should be performed prior to advanced imaging for the workup of hearing loss. Formal audiometric testing is also necessary to determine whether the hearing loss is conductive, sensorineural, or mixed.[3,6]
- MRI brain is generally preferred for sensorineural and mixed hearing loss, particularly for unilateral hearing loss, congenital loss, or for surgical planning.[1,4,5]
- CT orbits/temporal bone is preferred for cases of conductive hearing loss, trauma, or suspected bony or middle ear disorders.[1,4,5]
- Both may be supported for surgical planning (cochlear implants, petrous apex disorders).[1,4,5]
- 3D-Fast imaging employing steady state acquisition (3D-FIESTA) demonstrates significantly higher spatial resolution with superior imaging contrast between cranial nerves and CSF with a shorter acquisition time than conventional MRI scan.[7]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Tinnitus (HD-27.2)

HD.HL.0027.2.A
v2.0.2026

- A hearing evaluation is not required prior to imaging for tinnitus.
- The history in individuals with tinnitus should include a description of the tinnitus (episodic or constant, pulsatile or non-pulsatile, rhythmicity, pitch, quality of the sound), as well as inciting or alleviating factors. Continuous and pulsatile tinnitus are more concerning for an underlying and significant disorder. Audiometric assessment can be used as initial diagnostic testing particularly in individuals with tinnitus that is unilateral, persistent (>6 months) or associated with hearing difficulties (see **General Guidelines (HD-1.0)**)

Indications (Any one of the following)	Medically Necessary Imaging
• Clinical suspicion of mass lesion causing tinnitus • Asymmetric or unilateral non-pulsatile tinnitus (i.e., tinnitus that localizes to one ear) • Tinnitus associated with focal neurologic abnormalities, including asymmetric hearing loss • Persistent tinnitus after recent significant trauma. • Pulsatile tinnitus with or without concern for vascular lesion	• CT Orbits/Temporal Bone without contrast (CPT® 70480) **OR** • CT Orbits/Temporal Bone without and with contrast (CPT® 70482) **OR** • MRI Brain without and with contrast with attention to internal auditory canals (CPT® 70553) **OR** • MRI Brain without contrast with attention to internal auditory canals (CPT® 70551) **OR** • MRI Orbits/Face/Neck without contrast (CPT® 70540), with contrast CPT® 70542, or without and with contrast (CPT® 70543)
• Pulsatile tinnitus • Suspicion for vascular lesions	• MRA Head (CPT® 70544, CPT® 70545 OR CPT® 70546) **OR** • CTA Head (CPT® 70496) **AND/OR** • MRA Neck (CPT® 70547, CPT® 70548 or CPT® 70549) **OR** • CTA Neck (CPT® 70498) ◦ CTA Head and Neck (CPT® 70471) must be substituted if performed during the same session,

- Imaging is not medically necessary for bilateral non-pulsatile tinnitus without other neurologic signs or symptoms

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Limited MRI of the internal auditory canals (CPT® 70540, CPT® 70542, or CPT® 70543) is medically necessary when requested by the provider in place of a complete MRI Brain. Note: Limited MRI codes should not be used in addition to MRI Brain codes; IAC views are performed as additional sequences as part of the brain study (see **General Guidelines – Anatomic Issues (HD-1.1)**)
- CT and MR Venography (CTV and MRV) are reported with the same codes as the CTA/MRA counterpart. If arterial and venous CT or MR studies are both performed in the same session, only one CPT® code should be used to report both procedures.

Background and Supporting Information

- Non-pulsatile tinnitus may be described as ringing, buzzing, or clicking sensations which is constant and non-synchronous.
- Pulsatile tinnitus is a repetitive sound coinciding with the individual's heartbeat. The symptom may be subjective or objective.

Evidence Discussion (HD-27.2)

- A targeted history and clinical examination should be performed as the initial evaluation of an individual with tinnitus and determination as to whether the tinnitus is bothersome or not should be made before any imaging is considered.[3,6]
- Both MRI and CT have utility in diagnosing the etiology of tinnitus, particularly for concerns of mass lesions, or for tinnitus in conjunction with hearing loss or trauma.[1,4,5]
- MRA or CTA of the head and neck are also useful in the workup of pulsatile tinnitus or for suspicion of a vascular lesion.[1,4,5]

Neurosurgical Imaging (HD-28.1)

HD.NI.0028.1.A

v2.0.2026

- Typically, advanced imaging for monitoring disease for mass lesions occurs after biopsy (histologic) confirmation. This ensures appropriate determination related to phase of oncology imaging and alignment to appropriate diagnosis-specified guideline section.
  - However, repeat imaging by neurosurgeons or others of the management team for areas of the central nervous system (CNS) where permanent neurologic damage would be excessive with even a limited biopsy attempt is medically necessary.
  - Examples would include, but are not exclusive to: medically fragile individual, and tumors of the brainstem, eloquent areas of the brain, deep gray matter areas of the brain (ex. thalamus), and cavernous sinus.
- Repeat diagnostic head imaging is medically necessary when:
  - previous diagnostic head imaging is determined to be inadequate or additional imaging sequences/protocols are required by the neurosurgeon or the treatment team
  - prior imaging is greater than 6 months old

Neuronavigation (HD-28.2)

HD.NI.0028.2.A
v2.0.2026

- Neurosurgical navigation is “image-based” meaning that the necessary pre-operative CT and MRI images are used for navigation in the operating room (image acquisition). Accurate registration (a process to match the pre-operative images to the individual position) of pre-operative images is necessary to guide surgery regardless of the navigation system that is used. Registration can be point-based or surface matched routines to allow the surgeon to view the overlapping data sets and the current situation to allow navigation.
- The process of registration for neuronavigation via the acquisition of pre-operative CT and MRI images does not require a radiologist interpretation.
  - Diagnostic imaging codes are not medically necessary for the purpose of registration for neuronavigation.
  - Can be referenced by proprietary brand systems such as Brainlab or Stealth imaging procedures
  - See **Unlisted Procedures/Therapy Treatment Planning (Preface-4.3)** in the Preface Imaging Guidelines and **Unlisted Procedure Codes (ONC-1.5)** in Oncology in the Oncology Imaging Guidelines
- Advanced imaging for neuronavigation (image acquisition for registration for surgery) is medically necessary with one of each of the following as unlisted codes apply:
  - Unlisted MRI procedure code (CPT® 76498)
  - Unlisted CT procedure code (CPT® 76497)
  - Due to variances with techniques currently available for neuronavigation, the following are medically necessary:
    - CTA Head without and with contrast (CPT® 70496) or MRA Head (CPT® 70544, CPT® 70545 or CPT® 70546) (to avoid arterial and venous structures)
    - 3D (CPT® 76377 or CPT® 76376) (see **General Guidelines – Other Imaging Situations (HD-1.7)**)
  - Diagnostic imaging codes are only medically necessary if radiological supervision and interpretation of imaging is necessary with supporting documentation
    - MRI Brain without contrast (CPT® 70551) **OR** MRI Brain with contrast (CPT® 70552) **OR** MRI Brain without and with contrast (CPT® 70553) (contrast as requested) **AND/OR** CT Head without contrast (CPT® 70450) **OR** CT Head with contrast (CPT® 70460) **OR** CT Head without and with contrast (CPT® 70470) (contrast as requested)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Post-Operative Imaging (HD-28.3)

HD.NI.0028.3.A
v2.0.2026

- Post-operative imaging including MRI Brain without contrast (CPT® 70551), or MRI Brain with contrast (CPT® 70552), or MRI Brain without and with contrast (CPT® 70553) (contrast as request) or CT Head without contrast (CPT® 70450), or CT Head with contrast (CPT® 70460), or CT Head without and with contrast (CPT® 70470) (contrast as request) is medically necessary per neurosurgeon's or in concert with management team's request that includes, but not exclusive to the following indications:
  - Within 24-72 hours following brain surgery including to document the need for repeat surgery or if adjuvant intervention is necessary, concern or rule out for complication(s), evaluation if incomplete resection vs. consideration for plan for gross resection
  - Signs or symptoms indicating concern of clinical deterioration
  - Development of new neurological signs or symptoms
  - Follow-up on blood products, edema, and/or concern of cerebrospinal fluid leak
  - Follow- up imaging per condition-based guideline
- See additional condition-based guidelines:
  - Pediatric Neurosurgeries
    - See **Special Imaging Studies in Evaluation for Epilepsy Surgery (PEDHD-6.3)** in the Pediatric Head Imaging Guidelines
    - See **Modality General Considerations (PEDONC-1.3)** and **Pediatric CNS Tumors (PEDONC-4)** in the Pediatric and Special Populations Oncology Guidelines
  - Epilepsy
    - See **Perioperative Evaluations for Drug-Resistant Epilepsy (HD-9.2)**
  - Movement Disorders
    - See **Movement Disorders (HD-15.1)**
  - Pituitary or Sella Surgery
    - See **Pituitary (HD-19.1)**
  - Acoustic Neuroma and Other Cerebellopontine Angle Tumors
    - See **Acoustic Neuroma and Other Cerebellopontine Angle Tumors (HD-33.1)**
  - Central Nervous System Tumors
    - See **Primary Central Nervous System Tumors (ONC-2)** and **Brain Metastases (ONC-31.3)** in the Oncology Imaging Guidelines

Proprietary Information of UnitedHealthcare.

Evidence Discussion (HD-28)

v2.0.2026

- Imaging modalities for neurosurgical planning include MRI Brain and CT Head, along with vascular imaging.
- MRI Brain is the preferred modality for the evaluation of intracranial neoplasms and other conditions affecting the brain parenchyma, meninges or cranium, due to its superior soft tissue resolution when compared to CT Head.[19]
- CT Head is the preferred modality for evaluation of bony structures in the pre-operative setting.[22]
- For localization of relevant vascular anatomy prior to surgery, MRI angiography (MRA) head and neck or CT angiography (CTA) head and neck, may be appropriate.[20,21]
- Pre-surgical navigational imaging, whether by CT or MRI, allows a spatially accurate anatomical individual model for use in the treatment-planning process.[1,18]
- The requirements for surgical planning images differ from the requirements for diagnostic images, especially regarding the spatial accuracy of the images in the stereotactic coordinates used for localization and targeting.[1,18]
- Navigation based on an immediate pre-operative scan optimizes the accuracy of data used for initial surgical planning.[1] Navigation systems reduce length of surgery, lower incidence of wound infection and shorten length of post-operative hospital stay.[23]
- For post-operative imaging, CT Head is also useful for follow-up of intracranial hemorrhage, edema, hydrocephalus, shunts, and general post-operative follow-up. CT Head has the benefit of providing rapid evaluation if a post-operative complication is suspected.[19] Post-operative MRI Brain provides superior soft tissue resolution in less urgent scenarios.[22]

Sinus and Facial Imaging (HD-29.1)

HD.SI.0029.1.U
v2.0.2026

- CT Maxillofacial without contrast (CPT® 70486) or limited CT Sinus without contrast (CPT® 76380) is medically necessary for ANY of the following:
  - Acute sinusitis without resolution of symptoms after a minimum of 4 weeks of treatment (treatment can include an appropriate course and duration of empiric oral antibiotic, topical intranasal steroid, and/or nasal saline rinses.)
  - Concern for potential or suspected complicated sinusitis, which is sinusitis with actual or threatened orbital or intracranial extension
  - Recurrent sinusitis (4 or more episodes of acute bacterial rhinosinusitis within the past 12 months without symptoms or signs between episodes)
    - In practice, recurrent acute exacerbations of chronic rhinosinusitis are seen as well as recurrent acute rhinosinusitis with disease free intervals between the acute episodes. CT Maxillofacial without contrast (CPT® 70486) may still be medically necessary under chronic sinusitis definitions.
  - Suspicion of chronic sinusitis (**Note:** A trial of antibiotic therapy is not required prior to imaging if individual meets criteria for chronic sinusitis)
    - Chronic sinusitis is suspected when **BOTH** of the following are met:
      - At least two of the following on history and physical exam:
        - Mucopurulent drainage
        - Nasal obstruction or congestion
        - Facial pain, pressure, and/or fullness (may involve the anterior face, periorbital region, or manifest with headache that is localized or diffuse)
        - Decreased sense of smell (see **Taste and Smell Disorders (HD-2.1)** if anosmia, hyposmia, or dysosmia is an isolated symptom)

        AND
      - The aforementioned findings on history and physical exam have been present for at least 12 weeks
  - Sinus surgery is being considered (including Balloon Sinus Ostial Dilation or Functional Endoscopic Sinus Surgery)
  - Follow-up on incidentally noted sinus pathology (i.e., mucosal thickening, partial opacification of a sinus, or other indeterminate finding in incompletely visualized sinuses) on other imaging studies not performed for the purpose of evaluating sinus pathology, such as MRI Brain for headache, when requested by ENT for clinical correlation.
- Studies requested for the sole purpose of navigation for sinus surgery should be coded CPT® 77011 (CT guidance for stereotactic localization).

  - It is not appropriate to report both CPT® 70486 and CPT® 77011 for the same CT stereotactic localization imaging session (see **CT-, MR-, or Ultrasound-Guided Procedures (Preface-4.2)**) in the Preface Imaging Guidelines).
- For unexplained cough as the main symptom, and suspected Upper Airway Cough Syndrome (UACS) as the etiology, see **Cough (CH-3.1)** in the Chest Imaging Guidelines.
- For the immunocompromised individual with symptoms of sinusitis, the following are medically necessary:
  - CT Maxillofacial (contrast level as requested) when ordered by the surgeon or in consultation with the surgeon (i.e., ENT or ophthalmologist)
  - CT Maxillofacial with contrast (CPT® 70487) when there is suspicion for ANY of the following:
    - Orbital or facial cellulitis
    - Proptosis
    - Abnormal visual examination
    - Ophthalmoplegia
    - Fungal or vascular lesions visualized in nasal cavity
- CT Maxillofacial without contrast (CPT® 70486) **OR** CT Maxillofacial with contrast (CPT® 70487) **OR** MRI Orbits/Face/Neck without and with contrast (CPT® 70543) is medically necessary for the conditions below. However, CT Maxillofacial without contrast (CPT® 70486) may also be requested with MRI Orbits/Face/Neck without and with contrast (CPT® 70543) for surgical planning or osseous involvement.
  - Sinonasal obstruction, polyp, or suspected mass
  - Suspected orbital complication
  - Suspected invasive fungal sinusitis
  - Cystic fibrosis
  - Osteomyelitis and odontogenic infections, see **Skull Base Osteomyelitis (SBO) (HD-20.2)** and **Dental/Periodontal/Maxillofacial Imaging (HD-30.2)** for additional imaging modalities
- CT Maxillofacial without contrast (CPT® 70486) **AND** MRI Orbits/Face/Neck without and with contrast (CPT® 70543) are medically necessary when ordered by the ENT/specialist prior to planned biopsy of an intranasal mass — the extent and origin of which could not be determined by complete rhinologic exam alone
- MRI Brain without and with contrast (CPT® 70553) is medically necessary for suspected intracranial complication
- CT Orbits/Temporal bone without contrast (CPT® 70480) or CT Orbits/Temporal bone with contrast (CPT® 70481) is medically necessary performed alone or added to CT Maxillofacial for:
  - suspected orbital complications
- For skull base osteomyelitis (SBO), see **Skull Base Osteomyelitis (SBO) (HD-20.2)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Repeat imaging is medically necessary for ANY of the following scenarios:
  - An ENT specialist or any provider in consultation with an ENT specialist requests the imaging **and** ONE or more of the following:
    - There has been a follow-up visit since the previous imaging and there is no improvement after an additional 3 weeks of conservative treatment after initial imaging was completed:
      - The following imaging is medically necessary: CT Maxillofacial without contrast (CPT® 70486) **OR** limited CT Sinus without contrast (CPT® 76380)
    - There is a new abnormality on exam such as obstructing mass
      - The following imaging is medically necessary: CT Maxillofacial without contrast (CPT® 70486) **OR** CT Maxillofacial with contrast (CPT® 70487)
    - If sinus surgery is planned (including but not limited to Balloon Sinus Ostial Dilation or Functional Endoscopic Sinus Surgery) **AND** the most recent diagnostic CT Maxillofacial without contrast (CPT® 70486) is greater than 6 months old **OR** there is a change in clinical status as described above (i.e. interval completion of provider-prescribed medical management after the last CT was performed), a repeat diagnostic CT Maxillofacial without contrast (CPT® 70486) is supported for surgical planning.
      - Repeat CT Maxillofacial solely for the use of navigation during the sinus surgery (i.e., the most recent diagnostic CT Maxillofacial performed within the prior six months was only inadequate due to lacking anatomic landmarks or insufficient thinness of cuts) should be requested with CPT® 77011, not the diagnostic CPT® 70486.
      - 3D Rendering (CPT® 76376 or CPT® 76377) should not be reported in conjunction with CPT® 77011 (or CPT® 70486 if used). The procedure inherently generates a 3D dataset.
- Complications of ABRS (acute bacterial rhinosinusitis) are suspected based on:
  - Any constellation of symptoms worrisome for intracranial extension of infection or meningitis (i.e., severe headache, photophobia, fever, neck stiffness)
  - Severe headache
  - Facial swelling
  - Cranial nerve palsies
  - Orbital signs (cellulitis, impaired extraocular motility, decrease in vision or proptosis)
- Complications of ABRS are best assessed using iodine contrast-enhanced CT Maxillofacial with contrast (CPT® 70487) **OR** gadolinium-based MR imaging (MRI Orbits/Face/Neck without and with contrast (CPT® 70543) to identify extra-sinus extension or involvement; thus, this imaging is medically necessary.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

- CT Maxillofacial without contrast (CPT® 70486) may also be requested with MRI Orbits/Face/Neck without and with contrast (CPT® 70543) for surgical planning or osseous involvement.
- Suspected complications are the only medically necessary indication for MR imaging of the paranasal sinuses in the setting of ABRS.

For additional medical necessity criteria for CT Maxillofacial, see **Cone Beam Computed Tomography (CBCT) (HD-24.7)** and **Dental/Peridontal/Maxillofacial Imaging (HD-30.2)**)

Evaluation of potential candidates for Eustachian Tube balloon dilation procedure is with a one-time CT of the temporal bone without contrast (CPT® 70480). See medical necessity discussion in **Mastoid Disease or Ear Pain (HD-26.1)**. CT Sinus/Maxillofacial irrespective of contrast level is not supported if the sole indication for medical necessity is to evaluate a potential candidate for Eustachian Tube balloon dilation procedure, without meeting other HD-29.1 medical necessity criteria.

Background and Supporting Information

- Rhinosinusitis is defined as inflammation of the nasal cavity and adjacent paranasal sinuses. Acute sinusitis refers to symptom duration <4 weeks, subacute 4 to 12 weeks, and chronic >12 weeks. Complicated sinusitis refers to symptoms suggesting spread of disease into adjacent structures, including orbital or intracranial complications.
- There is no evidence to support advanced imaging of acute (<4 weeks) and subacute (4 to 12 weeks) uncomplicated rhinosinusitis.
- There is no evidence to support routine follow-up advanced imaging after treatment with clinical improvement of sinusitis.

Proprietary Information of UnitedHealthcare.

Evidence Discussion (HD-29.1)

v2.0.2026

- The American Academy of Otolaryngology – Head & Neck Surgery (AAO-HNS) recommended that clinicians should not obtain radiographic imaging for individuals with suspected uncomplicated Acute Rhinosinusitis (ARS), with imaging reserved for cases with clinically suspected complication. ARS refers to inflammation of the nasal cavity and paranasal sinuses lasting <4 weeks' duration.[1]
- Contrasted CT Maxillofacial is first line imaging for rhinosinusitis with suspected complications (orbital or intracranial). There is up to 91% accuracy with CT to detect orbital complications vs clinical exam alone. CT also is preferred for surgical planning. However, CT is often more useful for surgical planning and easier to perform. Non-contrasted CT sinus is not preferred but may be useful for surgical navigation. There is no relevant literature to support pre- and post-contrast CT imaging. MRI head or orbits/face/neck can be complementary with CT. MRI is more accurate than CT in the evaluation of soft tissues regarding intra-orbital and intracranial complications.[3,4]
- Chronic rhinosinusitis, acute recurrent bacterial sinusitis, non-invasive fungal sinusitis, and/or sinonasal polyposis are best evaluated initially with non-contrast CT Maxillofacial. CT is critical for surgical planning. Contrast is not necessary unless complications are suspected. MRI is not useful as the first-line study because of the lack of bony detail. In select cases, evaluation with MRI without and with IV contrast may be helpful to differentiate fluid secretions from inflamed mucosa and exclude an underlying obstructing mass.[3,4]
- Urgent CT Maxillofacial, either without or with IV contrast is first line imaging for any suspected invasive fungal sinusitis, as delay in diagnosis and surgical debridement could increase the already high risk of mortality. In cases of invasive fungal sinusitis, MRI without and with IV contrast of the head and/or orbits/face/neck is adjunctive to look for invasion into surrounding soft tissues as well as vascular complications.[3,4]
- CT and MRI are considered complimentary imaging modalities in the evaluation of a sinonasal mass—localizing and characterizing the lesions to determine their extent for treatment planning. If an MRI is planned, the CT may be performed without IV contrast since the main purpose of the CT is to evaluate osseous involvement.[3,4]

Temporomandibular Joint Disease (TMJ) (HD-30.1)

HD.TJ.0030.1.A
v2.0.2026

- MRI TMJ (CPT® 70336) is the diagnostic study of choice and is medically necessary for those who fail a minimum of 6 weeks of non-surgical treatment **AND** who are actively being considered for TMJ surgery.
  - The exception to the conservative management and surgical consideration requirement above includes the need to evaluate a recent trauma, dislocation, severe malocclusion, dental infection, or abscess.
- CT Maxillofacial without contrast (CPT® 70486) or without and with contrast (CPT® 70488) when there is suspicion of bony involvement based on prior x-ray or MRI
- Ultrasound (CPT® 76536) is medically necessary to look for the presence of a joint effusion and to evaluate cartilage and disk displacement with open and closed mouth imaging and to guide injections
- For TMJ imaging in individuals with Juvenile Idiopathic Arthritis (see **Temporomandibular Joint (TMJ) Imaging in Children (PEDHD-25)** in the Pediatric Head Imaging Guidelines)
  - MRI TMJ (CPT® 70336) is medically necessary annually for detecting silent TMJ arthritis in children and young adults with juvenile idiopathic arthritis as requested by a rheumatologist and/or oral/maxillofacial surgeon (OMS) and/or any provider in consultation with a rheumatologist or OMS.
  - Repeat imaging with MRI TMJ (CPT® 70336) in individuals with JIA is medically necessary for any of the following:
    - Change in signs or symptoms suggesting progression of disease
    - To monitor the effects of treatment[11]
  - Bone Scintigraphy/Bone Scan 3 Phase Study (CPT® 78315) in individuals over 12 years of age is medically necessary in anticipation or consideration of surgery.
- Jaw Asymmetry - Unilateral condylar hyperplasia is manifested by slow growth in areas of the mandible causing facial asymmetry. It is usually a self-limiting condition seen predominantly in individuals 12 to 30 years of age.
  - CPT® 78315 Bone Scan 3 Phase Study is medically necessary in anticipation or consideration of surgery.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion (HD-30.1)

- MRI is preferred for evaluation of the temporomandibular joint (TMJ) due to its superior contrast resolution and its ability to acquire dynamic imaging for demonstration of the functionality of the joint.[3,10]
- MRI is the imaging modality of choice for the diagnosis of internal derangement with an accuracy of 95% in assessing the disc position and form and 93% accuracy in assessing the osseous changes.[3]
- MRI is reserved for individuals with persistent symptoms in whom conservative measures have been ineffective, or in those with suspected internal joint derangement.[2,8,9] Imaging the TMJ prematurely may lead to harms including unnecessary surgery.[7]
- CT is the alternative modality for evaluating bony anatomy of the TMJ, fractures, degenerative changes, erosions, infections, congenital anomalies, acute and chronic inflammatory conditions, pre-operative evaluation and follow- up after surgery.[3,5,10]
- For pre-operative planning of unilateral condylar hyperplasia, bone scintigraphy is useful to predict ongoing condylar growth.[16]
- The diagnosis of chronic rheumatoid arthritis of the TMJ is established with contrast-enhanced MRI.[11] It is the preferred imaging study for diagnosis, disease progression, treatment monitoring and annual surveillance of TMJ arthritis in juvenile idiopathic arthritis (JIA).[11]

Dental/Periodontal/Maxillofacial Imaging (HD-30.2)

HD.TJ.0030.2.A
v2.0.2026

- Initial imaging with plain x-rays/dental x-rays is required.
- Cone beam CT is required for surgical planning and is, therefore, medically necessary for the potential indications listed below.
- Potential indications include but are not limited to:
  - Osteomyelitis and odontogenic infections (x-ray **NOT** required)
  - Bisphosphonate-related osteonecrosis of the jaw (x-ray **NOT** required)
  - Impacted teeth
  - Supernumerary teeth
  - Dentoalveolar trauma
  - Root resorption
  - Foreign body
  - Odontogenic cysts, tumors, or other jaw pathology
  - Orthognathic surgery for dentofacial anomalies
  - Maxillofacial bone graft planning
  - Dental implants related to tooth loss from injury, trauma, or jaw pathology such as cysts, tumors, or cancer
  - Post-operative imaging, including dental implants
- Cone Beam CT: Report with CPT® Codes: CPT® 70486, CPT® 70487, CPT® 70488, CPT® 70480, CPT® 70482 (see **Cone Beam Computed Tomography (CBCT) (HD-24.7)**)
- 3-D rendering (CPT® 76376 or CPT® 76377) should **NOT** be reported separately
- Cone beam CT (CBCT) may also be called i-CAT scanner or mini-CAT scanner
- For cleft palate indications (see **Other Indications for Sinus Imaging (PEDHD-5.6)**)
- For salivary gland indications (see **Salivary Gland Disorders (Neck-11.1)**)

Background and Supporting Information

Dental x-rays include panoramic, periapical, and/or occlusal x-rays.

Evidence Discussion (HD-30.2)

- CT is the radiologic modality for evaluating the bony anatomy of the head, acute and chronic inflammatory conditions, paranasal sinuses, pre-operative evaluation and follow-up after surgery.[1,5]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Recommendations by the American Association of Endodontists and the American Academy of Oral and Maxillofacial Radiology supported the use of cone beam CT (CBCT) as a supplemental imaging technique when conventional radiography fails to answer the clinical question and for surgical planning.[1,4,12]

Cranial Neuropathies (HD-31.1)

HD.CN.0031.1.A
v2.0.2026

Cranial Neuropathies Imaging Indications

- MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) is medically necessary for all individuals with new or worsening specific cranial nerve abnormalities.
- MRI Orbit/Face/Neck without contrast (CPT® 70540) **OR** MRI Orbit/Face/Neck without and with contrast (CPT® 70543) is also medically necessary for individuals with abnormalities in cranial nerves I, II, III, IV, V, VI, VII, IX, X, XI, or XII.
- CT Neck with contrast (CPT® 70491) is medically necessary for evaluation of abnormalities involving cranial nerves IX, X, XI, or XII.
- Imaging of the Brain and Orbit, Face and/or Neck is medically necessary concurrently when requested.
- For specific cranial neuropathies, see the corresponding guideline section listed below:
  - CN I: Olfactory nerve (see **Taste and Smell Disorders (HD-2.1)**)
  - CN II, III, IV, VI: Optic, Oculomotor, Trochlear and Abducens (see **Eye Disorders and Visual Loss (HD-32.1)**)
  - CN V: Trigeminal nerve (see **Trigeminal Neuralgia and other Centrally Mediated Facial Pain Syndromes (HD-10.1)**)
  - CN VII: Facial nerve (see **Facial Palsy (HD-6.1)**)
  - CN VIII: Vestibulocochlear nerve (see **Dizziness/Vertigo (HD-23.1)**, **Hearing Loss (HD-27.1)**, **Tinnitus (HD-27.2)**, **Acoustic Neuroma and Other Cerebellopontine Angle Tumors (HD-33.1)**. For isolated nystagmus (see **Eye Disorders and Visual Loss (HD-32.1)**)
  - CN IX: Glossopharyngeal nerve (see **Glossopharyngeal Neuralgia/ Glossopharyngeal Neuropathy HD-10.2)**)
  - CN X: Vagal nerve, imaging as detailed above (see also **Recurrent Laryngeal Palsy/Vocal Cord Palsy (Neck-7.1)**)
  - CN XI: Spinal accessory nerve, imaging as indicated above
  - CN XII: Hypoglossal nerve, imaging as indicated above
- For cranial neuropathies, whether isolated or multiple, due to clinically suspected stroke and/or vascular dissection (see **General Guidelines - CT and MR Angiography (CTA/CTV and MRA/MRV) (HD-1.5)**, **Headache and Suspected Vascular Dissection (HD-11.1)** and **Stroke/TIA (HD-21.1)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Background and Supporting Information

If a detailed clinical evaluation is unable to localize the site of the lesion, imaging of the entire course of the relevant cranial nerve is required, as cranial neuropathy can result from pathology affecting the nerve fibers at any point along the course of the nerve, from the cranial nerve origin in the brainstem to the end organ supplied by the nerve, requiring multiple imaging modalities.

The spinal trigeminal tract and nucleus extend from the midpons caudally into the upper cervical cord at the C2-4 levels. For suspected lesions of the spinal trigeminal tract and nucleus, imaging the brain stem and cervical spinal cord is supported. See **Trigeminal Neuralgia and other Centrally Mediated Facial Pain Syndromes (HD-10.1)**.

Number	Cranial Nerve Name	Nerve dysfunction on exam	Guideline Section in HD
I	Olfactory (smell)	Anosmia, hyposmia, parosmia, phatosmia	2
II	Optic (vision)	Optic neuritis, disc edema, papilledema, afferent pupillary defect APD)	16, 17, 32
III	Oculomotor (eye and pupil movement)	Eye "down and out", +/- dilated pupil, ptosis, diplopia	32
IV	Trochlear (depresses the eye)	Inability to depress the eye, diplopia	32
V	Trigeminal (sensation, mastication, taste)	Pain, numbness, corneal reflex loss, jaw deviation, trigeminal neuralgia, loss of taste	10
VI	Abducens (lateral movement of the eye)	Eye turns medially, inability to abduct, lateral rectus palsy, diplopia	32

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Number	Cranial Nerve Name	Nerve dysfunction on exam	Guideline Section in HD
VII	Facial (movement facial muscles, taste at 2/3, salivation/ lacrimation)	Inability to close eyelid, smile, nasolabial fold flattening, hyperacusis, impaired taste, salivation, lacrimation	6
VIII	Auditory, Vestibular, Vestibulochochlear (hearing and balance)	Hearing loss, tinnitus, vertigo, nystagmus, abnormal gait/ balance, sway on Romberg	23, 27, 33
IX	Glossopharyngeal (swallow, sensation, pharynx, posterior 1/3 tongue, parotid salivary gland)	Depressed gag reflex and palate, dysphagia, uvula deviation, throat pain	10, 2
X	Vagus (swallow, speech, parasympathetic to heart, lungs, GI tract)	Vocal cord paralysis, recurrent laryngeal nerve palsy, spasmodic dysphonia	7.1, 1.1
XI	Spinal Accessory (motor function neck/shoulder)	Sternocleidomastoid (SCM) weakness when turning head opposite, shoulder elevation, winging scapula	1.1
XII	Hypoglossal (tongue movement)	Tongue deviation, atrophy, fasciculation	1.1

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Number	Cranial Nerve Name	Nerve dysfunction on exam	Guideline Section in HD
INO	Internuclear Opthalmoplegia (lesion of medial longitudinal fasciculus, CN III, CN VI)	Impaired adduction of ipsilateral eye with nystagmus of abducting eye	16, 21, 22
Horner Syndrome	Disruption of sympathetic innervation to eye and face	Ptosis, miosis (constricted pupil), facial anhidrosis (absence of sweating)	32.2, 11.3

Evidence Discussion (HD-31.1)

- Imaging of each body section along the entire course of the relevant cranial nerve may be medically necessary if detailed clinical evaluation is unable to localize the site of the lesion. Cranial neuropathy can result from pathology affecting the nerve fibers at any point along the course of the nerve, from the cranial nerve origin in the brainstem to the end organ supplied by the nerve, indicating need to image multiple body sections.[1,2] MRI Brain, Orbits, Face, Neck, or any combination may be necessary depending on the clinical need.[1,2]
- MRI is the standard modality for imaging the cranial nerves.[2,3]
- CT Neck is useful to exclude neck masses when evaluating either isolated or multiple lower cranial neuropathies.[2] CT may be complementary to MRI in characterizing skull base erosions, calcifications, and skull base foramina.[2]

Eye Disorders and Visual Loss (HD-32.1)

HD.VL.0032.1.A
v2.0.2026

- For specific conditions - See ***Background and Supporting Information*** that include table of abbreviations
- For eye pain, also refer to **Trigeminal Neuralgia/Trigeminal Neuropathy (HD-10.1)** and/or **Multiple Sclerosis and Related Conditions (HD-16)**
- Examination of ocular complaints and visual loss may include evaluation of pupillary responses, extraocular motility, visual acuity, visual field testing, intraocular pressures, external examination, slit lamp examination, and/or fundoscopic exam of retinae. An exam performed by a neuro-ophthalmologist, ophthalmologist, neurologist, or an optometrist meets this requirement.
- MRI Orbits/Face/Neck without contrast (CPT® 70540) **OR** MRI Orbits/Face/Neck without and with contrast (CPT® 70543) **OR** CT Orbits/Temporal bone with contrast (CPT® 70481) **OR** CT Orbits/Temporal bone without contrast (CPT® 70480) **AND/OR** MRI Brain without contrast (CPT® 70551) **OR** MRI Brain without and with contrast (CPT® 70553) is medically necessary for:
  - unexplained vision loss
  - optic atrophy (cranial nerve II)
  - optic neuropathy (cranial nerve II)
  - papilledema/optic disc swelling (cranial nerve II) (see **Cranial Neuropathies (HD-31.1)** and **Papilledema/Pseudotumor Cerebri (HD-17.1)**)
  - Afferent Pupillary Defect (APD) or Relative Afferent Pupillary Defect (RAPD)
  - chiasmal symptoms/signs (including bitemporal field deficit)
  - ophthalmoplegia, diplopia, and/or cranial nerve palsy (specifically CN III, IV, and VI, see **Cranial Neuropathies (HD-31.1)**)
  - nystagmus
- For optic disc edema/papilledema, CT Head without contrast (CPT® 70450) is medically necessary to assess for space-occupying processes such as intracranial hemorrhage, mass effect and hydrocephalus.
- For suspected optic neuritis, MRI is the preferred modality (see **Multiple Sclerosis (MS) (HD-16.1)** and **Neuromyelitis Optica Spectrum Disorders (HD-16.2)**)
- Visual field defects are associated with retrochiasmal pathology (see **Stroke/TIA (HD-21.1)** or **Primary Central Nervous System Tumors (ONC-2)** in the Oncology Imaging Guidelines or **Brain Metastasis (ONC- 31.3)** in the Oncology Imaging Guidelines)
- MRI Orbits/Face/Neck without contrast (CPT® 70540) or MRI Orbits/Face/Neck without and with contrast (CPT® 70543) or CT Orbits/Temporal bone with contrast (CPT® 70481) is medically necessary for:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - exophthalmos (including thyroid eye disease), enophthalmos or non-traumatic orbital asymmetry
  - suspected orbital cellulitis or atypical pre-septal cellulitis, uveitis, or scleritis
  - orbital mass or metastasis
  - orbital inflammatory syndrome (orbital pseudotumor) and dacryocystitis or dacryoadenitis
- CT Orbits/Temporal bone without contrast (CPT® 70480) and/or CT Head without contrast (CPT® 70450) is/are medically necessary for:
  - orbital trauma with visual defect
  - exophthalmos (including thyroid eye disease)
- CT Orbits/Temporal bone without contrast (CPT® 70480) or CT Orbits/Temporal bone with contrast (CPT® 70481) or CT Orbits/Temporal bone without and with contrast (CPT® 70482) or CT Maxillofacial without contrast (CPT® 70486) or CT Maxillofacial with contrast (CPT® 70487) or CT Maxillofacial without and with contrast (CPT® 70488) is medically necessary for:
  - pre-operative planning for procedures including dacryocystorhinostomy (DCR) to correct nasolacrimal duct obstruction (NLDO)
- When requested by the surgeon or in consultation with surgeon, contrast level as requested is medically necessary. This includes requests from ophthalmologists and oculoplastic surgeons. Contrast level preference may vary per institutional protocol.
- MRA Head (CPT® 70544, CPT® 70545, or CPT® 70546) or CTA Head (CPT® 70496) is medically necessary for suspicion of intracranial aneurysm, including third nerve palsy with pupillary involvement (see **Cerebral Aneurysms (HD-12.1)**
- MRA Head (CPT®70544, CPT®70545, or CPT®70546) or CTA Head (CPT®70496) **AND/OR** MRA Neck (CPT®70547, CPT®70548, or CPT®70549) or CTA Neck (CPT® 70498) is medically necessary for evaluation of diplopia due to suspected stroke or TIA (see **Cerebral Aneurysms (HD-12.1)**)
  - CTA Head and Neck (CPT® 70471) must be substituted for CTA Head (CPT®70496) and CTA Neck (CPT® 70498) if performed during the same session.
- Amaurosis Fugax (see **Stroke/TIA (HD-21.1)**)
  - Individuals describe a transient darkening or loss of vision, typically monocular
- Central Retinal Artery Occlusion, Branch Retinal Artery Occlusion, and Ophthalmic Artery Occlusion (see **Stroke/TIA (HD-21.1)**)
  - Individuals describe a sudden monocular loss of vision or visual field. Etiology is usually embolic and is considered a stroke to the retina
- There is currently no data to support advanced imaging while on Tepezza® (teprotumumab). However, advanced imaging is medically necessary for any of the following concerns:
  - Neurologic symptoms or ophthalmologic symptoms

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- To reassess compressive optic neuropathy (symptoms/signs of compressive optic neuropathy include APD, decreased visual acuity, and/ or visual field defects)
- For non-response to Tepezza® (teprotumumab) or relapses, worsening proptosis, diplopia, lid retraction, or optic neuropathy
- For surgical planning for orbital decompression, strabismus surgery, or lid surgery
  - When any of the above concerns are present, **ONE** of the following modalities is medically necessary:
    - MRI Orbits/Face/Neck without contrast (CPT® 70540)
    - MRI Orbits/Face/Neck without and with contrast (CPT® 70543)
    - CT Orbits/Temporal bone with contrast (CPT® 70481)
    - CT Orbits/Temporal bone without contrast (CPT® 70480)
    - CT head without contrast (CPT® 70450)

- Autoimmune Retinopathy
  - Suspicion for CAR (Cancer associated retinopathy) or MAR (melanoma associated retinopathy) syndromes (see **Paraneoplastic Syndromes (ONC-30.3)** in the Oncology Imaging Guidelines)
- Oncologic conditions
  - Retinoblastoma (see **Retinoblastoma (PEDONC-12)** in the Pediatric and Special Populations Oncology Imaging Guidelines)
  - Uveal (choroidal) melanoma (see **Ocular Melanoma (ONC-5.9)** in the Oncology Imaging Guidelines)
  - Biopsy results are not required before initial staging
- Vasculitis including Temporal Arteritis (Giant Cell Arteritis) (see **Cerebral Vasculitis (HD-22.1)**)

Background and Supporting Information

- Imaging Non-Indications
  - Imaging is not necessary if visual loss or ocular symptom/sign is due to known intrinsic eye disease, such as refractive errors, amblyopia, pterygium, subconjunctival hemorrhage, conjunctivitis, cataracts, macular degeneration, central serous retinopathy, retinal vein occlusion, retinal detachment, etc. Monocular diplopia is not an indication for imaging. Physiologic anisocoria and surgically distorted pupils are not indications for imaging. Anisocoria may be physiologic or non-physiologic when the difference in pupil diameter between the two eyes is up to 2 mm.
  - Imaging is not typically necessary in cases of ptosis without concern for Horner's or 3rd nerve palsy
- Advanced imaging of the brain and orbit are not routinely paired.
  - Suspicion for disorders involving both regions is needed to image both regions.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Orbital imaging alone may be sufficient unless other signs or symptoms suggest brain involvement.
- Thyroid function and iodine contrast: thyroid dysfunction can occur in susceptible individuals after iodine exposure.

List of Abbreviations and Meanings:

Abbreviation	Meaning
AC	anterior chamber
APD	afferent pupillary defect (see RAPD)
BCVA	best-corrected visual acuity
C3F8	gas bubble injected into vitreous cavity during retina surgery
cc	with correction (current new or old glasses or contact lenses)
CP	color plates
C/S	conjunctiva/sclera
CSME	clinically significant macular edema
CVF	confrontation visual field (testing of gross field of view)
D	disc, optic nerve head
DBH	dot blot hemorrhages
DCR	dacryocystorhinostomy
DFE	dilated fundus exam
E	esophoria at distance
E'	esophoria at near
EOM	extraocular movements
ERM	epiretinal membrane
ET	esotropia at distance

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Abbreviation	Meaning
E(T)	inIntermittent esotropia at distance
ET'	esotropia at near
E(T)'	intermittent esotropia at near
GVF	Goldmann visual field test
HT	hypertropia
HVF	Humphrey visual field test (automated perimetry)
I	iris
Ishihara	commonly used color plates
IOP	intraocular pressure
K	cornea
LF	levator function
LFH	lid fissure height
LLL	lids, lashes, lacrimal gland
M	macula
ME	macular edema
MH	macular hole
MP	membrane peel
MRD1	margin-reflex distance from upper lid margin to pupillary light reflex
MRx	manifest refraction
NI	no improvement
NLDO	nasolacrimal duct obstruction
NSC or NS	nuclear sclerotic cataract
OD	right eye

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Abbreviation	Meaning
OS	left eye
ortho	eyes are aligned on the same target
OCT	optical coherence tomography
P	periphery
PD	prism diopter
ph or PH	pinhole (crude assessment of best-corrected visual acuity)
PPV or PPVx	pars plana vitrectomy
PVD	posterior vitreous detachment
RAPD	relative afferent pupillary defect (see APD)
RD	retinal detachment
RT	retinal tear
SB	scleral buckle
sc	without correction
SF6	gas bubble injected into vitreous cavity during retina surgery
SLE	slit lamp examination
SO	silicone oil
SRF	subretinal fluid
Ta	applanation tonometry (intraocular pressure measurement)
Tp	tonopen tonometry (intraocular pressure measurement)
V	vessels
Va	visual acuity
VF	visual field testing (formal automated perimetry versus confrontation visual field testing)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Abbreviation	Meaning
X	exophoria at distance
X'	exophoria at near
XT	exotropia
X(T)	intermittent exotropia at distance
XT'	exotropia at near
X(T)'	intermittent exotropia at near

Evidence Discussion (HD-32.1)

- When evaluating suspected or known issues involving the eye, orbit, and/or brain, consideration must be given to:
  - whether or not imaging is required,
  - which body area should be imaged, i.e., brain, orbits, or both, and
  - which modality, MRI or CT, would best provide the information needed while exposing an individual to the least risk.
- The body area imaged should be reasonably expected to be potentially involved in the suspected condition. The angles of and distance between each view differ between brain imaging and orbital imaging. There are circumstances in which imaging of both the brain and orbits may be useful, as in conditions that can affect both locations or for which evaluation by the different techniques provides useful information.
- Soft tissue detail such as neural tissue is well-visualized by MRI.
- Calcification, bone, and hemorrhages are well-visualized by CT.
- MRI carries no risk of radiation exposure but is sensitive to motion, takes longer, and may require sedation or anesthesia for a longer duration than would be required for CT. Certain populations may have psychological or physical difficulty undergoing MRI scans, including children, those with obesity, movement disorders, anxiety, or claustrophobia.
- CT carries risk of radiation exposure but is less sensitive to motion and has a shorter duration than MRI. Imaging more than one body area increases the exposure dose. Certain populations may carry higher risk of detrimental effects from exposure, including children.
- Radiation exposure of the ocular lens contributes to cataract formation. Radiation doses vary between CT scans due to differences in scanning technique, number of images taken per CT, body area scanned, CT machines used, and facility protocols. The cancer risk of radiation exposure in diagnostic CT is considered extremely

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

low, and the benefit of an appropriately indicated CT examination far outweighs the potential risk.[25] Cataract formation is among the earliest radiation associated pathologies in the eye. The Beaver Dam Eye Study, a population-based study of common age-related eye diseases, found that nuclear sclerosis and posterior subcapsular opacity were significantly associated with CAT scans.[25]

Pupillary Abnormalities Including Horner's Syndrome (HD-32.2)

HD.VL.0032.2.A

v2.0.2026

- Examination of ocular complaints may include evaluation of pupillary responses, extraocular motility, visual acuity, visual field testing, intraocular pressures, external examination, slit lamp examination and/or funduscopic exam of the retinae. An exam performed by a neuro-ophthalmologist, ophthalmologist, neurologist, or an optometrist meets this requirement.
- Anisocoria and Other Pupillary Disorders
  - Physiologic anisocoria (difference in pupil diameter between the two eyes of typically 2 mm or less) and surgically distorted pupils are not indications for advanced imaging.
  - Dilated pupil from suspected Third nerve palsy (see **Eye Disorders and Visual Loss (HD-32.1)**)
  - Horner's Syndrome (See below)
- Horner's Syndrome (anisocoria, ptosis, and ipsilateral anhidrosis) is caused by disruption of sympathetic innervation to the eye and face. Definitive diagnosis may be established by pharmacologic testing of the pupillary response with eye drops. Evaluation and imaging depends on determining whether the cause is a central lesion (brainstem or cervical spinal cord), pre-ganglionic lesion (spinal cord or sympathetic chain in the chest), or post-ganglionic lesion (neck or carotid artery).
- MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) is medically necessary for suspected intracranial or brainstem lesions
- MRI Cervical Spine without contrast (CPT® 72141) or MRI Cervical Spine without and with contrast (CPT® 72156) is medically necessary for suspected spinal cord abnormality
- MRI Brachial plexus for Horner syndrome with traction or trauma to the brachial plexus
  - Any **ONE** of the following are medically necessary:
    - MRI Upper Extremity other than joint without contrast (CPT® 73218)
    - MRI Upper Extremity other than joint without and with contrast (CPT® 73220)
    - MRI Chest without contrast (CPT® 71550)
    - MRI Chest without and with contrast (CPT® 71552)
    - MRI Neck without contrast (CPT® 70540)
    - MRI Neck without and with contrast (CPT® 70543)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- CT Chest with contrast (CPT® 71260) or MRI Chest without and with contrast (CPT®71552) is medically necessary for suspected chest mass
- CT Neck with contrast (CPT® 70491) or MRI Face/Neck/Orbits without and with contrast (CPT®70543) is medically necessary for suspected neck mass
- CTA Neck without and with contrast (CPT® 70498) or MRA Neck (CPT® 70547, CPT® 70548, or CPT® 70549) is medically necessary for suspected carotid injury or dissection
- MRI Orbits/Face/Neck without contrast (CPT® 70540), MRI Orbits/Face/Neck without and with contrast (CPT® 70543) or CT Orbits/Temporal bone with contrast (CPT® 70481) is medically necessary for suspected orbital lesion or mass

Evidence Discussion (HD-32.2)

- In the evaluation of Horner Syndrome, if a detailed clinical evaluation is unable to localize the site of the lesion, imaging of the entire course of the relevant oculosympathetic pathway is required, as symptoms may result from pathology affecting the nerve fibers at any point along the course of the pathway, requiring multiple imaging modalities.[35] MRI Brain, MRI Orbits/Face/Neck, MRI Cervical Spine and/or MRI Brachial plexus studies may be necessary, depending on the clinical presentation.[1,2,4,35]
- CT Neck is useful to exclude neck masses.[2,35] CT may be complementary to MRI in characterizing skull base erosions, calcifications, and skull base foramina.[35]
- For suspected lung masses associated with Horner syndrome, such as for evaluation of Pancoast tumors, chest imaging is recommended. A mass may be diagnosed on a CT Chest or an MRI Chest.[2,4,24] CT scans provide 60% sensitivity, 65% specificity, and 63% accuracy in defining the local extent of tumor, in contrast to MRI with a sensitivity of 88%, a specificity of 100%, and an accuracy of 94%.[24] MRI of the chest is a more accurate pre-operative examination in identifying the local extent of a Pancoast tumor.[24]
- For suspected carotid injury or dissection, vascular imaging with either CT Angiography (CTA) neck or MR Angiography (MRA) neck is medically necessary, depending on the individual's risk and benefit profile.[2,4,6]

Acoustic Neuroma and Other Cerebellopontine Angle Tumors (HD-33.1)

HD.AC.0033.1.A

v2.0.2026

- Acoustic neuroma and vestibular schwannoma may be used interchangeably
- Initial diagnosis is usually made during evaluation for asymmetric hearing loss and/or vertigo (see **Dizziness, Vertigo and Syncope (HD-23)** and **Hearing Loss and Tinnitus (HD-27)**) for evaluation of those problems)
- MRI Brain without and with contrast (CPT® 70553), which should be done with attention to the internal auditory canals, is medically necessary for initial diagnosis.
- MRI Brain without contrast (CPT® 70551) is medically necessary if performed with FIESTA protocol
- MRI Orbits/Face/Neck without and with contrast (CPT® 70543) with audiologic or clinical features of retrocochlear hearing loss and a negative MRI Brain and in the rare individual in whom a detailed search is medically necessary for both a lesion of the cerebellopontine angle **and** lesions of the cerebral hemispheres
- Repeat MRI Brain (contrast as requested) is medically necessary 6 months after diagnosis, then annually for 5 years and thereafter per neurologist, neurosurgeon, or otolaryngologist, or any provider in consultation with a neurologist, neurosurgeon, or otolaryngologist.
- MRI Brain without and with contrast with attention to the internal auditory canals (CPT® 70553) is medically necessary after surgical resection and following stereotactic radiation therapy at 6 to 12 months to document the completeness of tumor removal and to serve as a baseline for further follow-up. Additional follow-up is done annually for 5 years and every 2 years thereafter.
- Limited MRI of the internal auditory canals (CPT® 70540, CPT® 70542, or CPT® 70543) is medically necessary when requested by the provider in place of a complete MRI Brain. Note: Limited MRI codes should not be used in addition to MRI Brain codes; IAC views are performed as additional sequences as part of the brain study. (See **General Guidelines – Anatomic Issues (HD-1.1)**)
- See **Primary Central Nervous System Tumors- General Considerations (ONC-2.1)** in the Oncology Imaging Guidelines for additional imaging requests for surgery

Evidence Discussion (HD-33)

- MRI Brain is the preferred initial imaging modality for evaluation of persistent vertigo, vertigo associated with an abnormal neurologic exam, vertigo due to a suspected central cause, pulsatile or asymmetric tinnitus, and/or hearing loss.[8,9]
- CT Head is not recommended for the initial evaluation of suspected acoustic neuroma due to inferior soft tissue resolution when compared to MRI Brain. In addition, MRI Brain provides better visualization of the cerebellum, posterior fossa, and cranial nerves.[8]
- MRI Brain, in this clinical scenario, is performed using specialized internal auditory canal (IAC) protocols, which include thin-section sequences to evaluate for vascular loops and small vestibular schwannomas.[10]
- MRI Brain can diagnose lesions in the cerebellopontine angle including schwannoma, meningioma, and other posterior fossa tumors.[10]
- 3D-Fast imaging employing steady state acquisition (3D-FIESTA) demonstrates significantly higher spatial resolution with superior imaging contrast between cranial nerves and CSF with a shorter acquisition time than conventional MRI scan.[4]
- Follow-up imaging is recommended 6 months after diagnosis to evaluate for rapid growth, then annually for 5 years.[3,6,7] After 5 years, tumor growth that has remained stable is unlikely but may still occur, therefore, lifelong surveillance is advised with longer imaging intervals.[7]
- Follow-up imaging after surgical resection and/or stereotactic radiosurgery to assess residual tumor and treatment response is performed at 6-12 months with additional follow-up annually for 5 years and every 2 years thereafter.[5,6]

Pineal/Colloid Cysts (HD-34.1)

HD.PT.0034.1.A
v2.0.2026

Pineal Cysts

Pineal cysts are generally discovered incidentally and do not require surgical intervention.

- MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) is medically necessary for initial evaluation of pineal cysts if not already completed.
- Repeat MRI Brain is not medically necessary for most individuals with pineal cysts, but MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) is medically necessary for the following:
  - New or worsening headache or focal neurologic deficits suggesting progression of cyst
  - Pre-operative planning

Colloid Cysts

- MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) is medically necessary for the initial evaluation of colloid cysts if not already completed.
- Repeat MRI Brain without contrast (CPT® 70551) or without and with contrast (CPT® 70553) is medically necessary for colloid cysts for the following:
  - In the presence of symptoms including syncope
  - Evaluation of CSF flow (CPT® 70551)
  - When requested by a neurologist or neurosurgeon or any provider in consultation with a neurologist or neurosurgeon

Evidence Discussion (HD-34)

- MRI Brain is the preferred modality for the evaluation of intracranial cysts, due to its superior soft tissue resolution when compared to CT Head.[1,4]
- Follow-up imaging of pineal cysts is supported for new or worsening headaches, focal neurologic deficits, and/or for surgical planning, otherwise, routine follow up is not supported.[2,3]
- In contrast to pineal cysts, colloid cysts may lead to sudden obstruction of cerebrospinal fluid flow at the foramen of Monro, resulting in neurologic symptoms, including syncope. Other than this scenario, follow-up imaging indications are similar to pineal cysts.[1,5]

Arachnoid Cysts (HD-35.1)

HD.AR.0035.1.A
v2.0.2026

Arachnoid cysts arise in the middle or posterior fossa, and the majority of lesions are discovered incidentally and do not require surgical intervention.

- MRI Brain without contrast (CPT® 70551) or MRI Brain without and with contrast (CPT® 70553) is medically necessary for initial evaluation of arachnoid cysts if not already completed.
- Repeat MRI Brain is not medically necessary for most individuals with arachnoid cysts, except in the following scenarios:
  - New or worsening headache or focal neurologic deficits suggesting progression of cyst
  - Pre-operative planning
  - When requested by a neurologist or neurosurgeon or any provider in consultation with a neurologist or neurosurgeon

Evidence Discussion (HD-35)

- MRI Brain is the preferred modality for evaluation and follow up of intracranial arachnoid cysts, due to its superior soft tissue resolution when compared to CT Head.[1,3]
- Most intracranial arachnoid cysts remain asymptomatic and follow up imaging is not routinely supported. Surgical intervention is reserved for those with symptoms.[1,2]

Nuclear Medicine (HD-36.1)

HD.NM.0036.1.A
v2.0.2026

Nuclear medicine studies used in the evaluation of some head/brain disorders, and other rare indications as well.

- Brain Scintigraphy with or without vascular flow (any one of CPT® 78600, CPT® 78601, CPT® 78605, or CPT® 78606)
- Brain Imaging Radiopharmaceutical Localization SPECT (CPT® 78803)
  - Immunocompromised individuals with mass lesion detected on CT or MRI for differentiation between lymphoma and infection
  - In distinguishing recurrent brain tumor from radiation necrosis
  - Can be performed with vasodilating agent acetazolamide (Diamox) to assess functional reserve capacity to predict critically reduced perfusion in individuals with chronic cerebrovascular disease (for example, in Moya-Moya disease) and identify individuals who might benefit from an extracranial-to-intracranial (EC-IC) bypass to augment Cerebral Blood Flow, and to assess pre-operatively the potential for ischemia following carotid artery sacrifice. See **Moyamoya Syndrome/Disease (HD-21.5)**
- Brain Imaging Vascular Flow (CPT® 78610)
  - Cerebral ischemia
  - Establish brain death
- CSF Leakage Detection (CPT® 78650)
  - Evaluation of CSF rhinorrhea, otorrhea, or refractory post-lumbar puncture headache
  - Suspected normal pressure hydrocephalus with gait disturbance and either dementia or urinary incontinence
- Radiopharmaceutical Dacryocystography (CPT® 78660)
  - Suspected obstruction of nasolacrimal duct due to excessive tearing
- Cisternogram (CPT® 78630), see **Low-Pressure Headache and CSF Leak (HD-11.15)** and **Facial Trauma (HD-13.2)**
- Cerebrospinal Ventriculography (CPT® 78635) and Nuclear Medicine Shunt Evaluation (CPT® 78645) and CSF Flow SPECT (CPT® 78803), see **Hydrocephalus Shunts (HD-11.14)**
- DAT-SPECT **OR** Fluorodopa F (F-DOPA) PET Brain see **Lewy Body Dementia (LBD) – SPECT Brain Scan and PET (HD-8.3)** and **Movement Disorders (HD-15.1))**
- Jaw Asymmetry - see **Temporomandibular Joint Disease (HD-30.1)**

Evidence Discussion (HD-36)

- Nuclear medicine studies are adjunct, functional imaging modalities in the evaluation of a variety of neurologic conditions and are generally helpful when structural brain imaging modalities are unable to provide answers to complex clinical questions.
- The American Academy of Neurology practice guideline recommends brain SPECT to assist with prognostication in adults with traumatic brain injuries.[4]
- Single-photon emission CT (SPECT) is the most readily available nuclear medicine technique for assessment of cerebral hemodynamics.[2] Brain SPECT has also been validated for evaluation of cerebrovascular reactivity to acetazolamide (ACZ) challenge in individuals with various types of vaso-occlusive disease, including Moyamoya disease.[2,7]
- Brain SPECT has been used in the evaluation of stroke, TIA, monitoring of medical or surgical therapy, assessment of cerebral blood flow reserve, and estimation of prognosis. The sensitivity of brain SPECT for acute stroke localization is 85.5% with a specificity of 97.6%.[6]
- Brain SPECT used with specific perfusion agents is useful in distinguishing radiation effects from residual or recurrent tumor, and/or for distinguishing cerebral lymphoma from infection, a distinction not always possible with CT or MRI.[6]
- Dacryocystography is supported to localize the lacrimal drainage system and evaluate for suspected obstruction in the nasolacrimal duct.[9]
- Radionuclide CSF shunt studies can evaluate shunt patency, differentiate proximal versus distal obstruction, and localize the site of obstruction. The combination of CT and radionuclide is more sensitive than CT alone in diagnosing shunt malfunction.[8]
- CT head cisternography in the evaluation of CSF leak has a sensitivity range between 85%-92%. This modality is particularly useful when there are multiple potential CSF leak sites. Radionuclide cisternography is useful for confirming the presence of a CSF leak.[5]

General Guidelines Sleep-Related Imaging (HD-37.1)

HD.SL.0037.1.A
v2.0.2026

- Hypersomnolence:
  - When there are focal neurologic signs or suspicion for an inflammatory neurologic process as the etiology. Recognition and treatment of a comorbid sleep disorders is paramount, and a complete neurologic history and examination should precede any request for advanced imaging.
    - MRI Brain without and with contrast (CPT® 70553) **OR**
    - MRI Brain without contrast (CPT® 70551)
- Central Sleep Apnea:
  - For unexplained central sleep apnea syndrome when a primary CNS etiology is suspected, i.e., unassociated with CHF, COPD, or other potential etiology. Specific etiologies should be stated for imaging requests, including but not limited to, suspected Chiari malformation, stroke, CNS demyelinating disease, posterior fossa lesion, anoxia, or infection.
    - MRI Brain without and with contrast (CPT® 70553) **OR**
    - MRI Brain without contrast (CPT® 70551)
- Obstructive Sleep Apnea (OSA):
  - Advanced imaging is not medically necessary in the evaluation and management of obstructive sleep apnea.
  - The gold standard for OSA diagnosis, evaluation and management is a sleep study.
  - See **Initial Sleep Diagnostic and Treatment Testing (SL-2.1)**
- Oral Appliance:
  - There is a lack of published case-controlled clinical studies in Sleep literature validating the use of advanced imaging with respect to oral appliance therapy (pre-treatment assessment).
  - Previous literature has demonstrated support for cephalometric studies (x-ray) in predicting treatment success.
  - Nasoendoscopy (sedated and non-sedated with provocative maneuvers such as Mueller maneuver) has been helpful as well in this regard.
  - Routine use of advanced imaging is not medically necessary at this time.
- Upper Airway Surgery:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- There is a lack of published case-controlled clinical studies in sleep literature validating the use of advanced imaging for upper airway surgery (pre-treatment assessment).
  - Examples of upper airway surgery include, but are not limited to, hypoglossal nerve stimulation, uvulopalatopharyngoplasty (UPPP), turbinate reduction, and nasal septoplasty
- For congenital anomalies, see **Craniosynostosis Imaging (PEDHD-8.1)** and **Facial Anomalies (PEDHD-8.2)**
- For dentofacial abnormalities, see **Dental/Periodontal/Maxillofacial Imaging (HD-30.2)**
- Routine use of advanced imaging is not supported at this time.

- For suspected sleep-related seizure imaging (see **Epilepsy and Other Seizure Disorders (HD-9)**)

Evidence Discussion (HD-37.1)

- An individual's management is rarely impacted by structural brain imaging in the evaluation of unexplained hypersomnolence. Instead, a thorough evaluation can result in an accurate diagnosis while safeguarding individuals from unnecessary exposure to radiation and over-reliance on incidental imaging findings as potential contributors to the symptom(s).
- Literature supports use of drug-induced sleep endoscopy (DISE) to predict effectiveness of upper airway surgery, particularly in individuals seeking upper airway stimulation or maxillomandibular advancement.[16,17]
- Studies have demonstrated how upper airway MRI and CT can be used to determine sites of collapse in OSA patients.[14,15] Information from imaging could assist with determining which surgical interventions should be considered. Additionally, imaging may be helpful to determine why upper airway surgery is ineffective post-surgically.[14] However, there are no large clinical trials that have shown improved surgical outcomes utilizing data from pre-treatment advanced imaging for OSA.
- The appropriate step in care for individuals with disordered sleep is to evaluate their breathing with polysomnography. Advanced imaging can lead to gaps in care and ineffective treatment of disordered sleep patterns. Instead, emphasis should be placed on holistic evaluation, including sleep history and sleep testing. Radiography (x-rays), 3D Advanced Imaging, or dynamic nasopharyngoscopy are not supported by evidence to being superior over polysomnography at this time.

General Guidelines (MS-1.0)

MS.GG.0001.0
v2.0.2026

General Criteria

Information regarding the purpose, development, management and review/revision of these guidelines can be found in the **Preface to the Imaging Guidelines** (the Preface). The Preface provides guidance on the clinical documentation and information that should be submitted in order to establish the medical necessity of advanced imaging. The Preface also contains information on special considerations that may be pertinent to criteria-based reviews for advanced imaging (e.g., pediatric vs. adult, gender identity, health plan policies, national or local mandates). Providers should review and be familiar with all information in the Preface.

These musculoskeletal (MSK) imaging guidelines are intended for the further investigation of non-spinal, MSK conditions or concerns (e.g., shoulder, elbow, wrist, hand, arm, pelvis, hip, knee, ankle, leg, foot). Imaging guidelines for spinal conditions or concerns are located in **Spine Imaging Guidelines.**

Before any request for advanced diagnostic imaging of musculoskeletal concerns will be considered ALL of the following must be complete and clearly documented. The following criteria apply to all requests for advanced imaging, details, or exceptions, will be provided within each specific section throughout the guideline:

- There must be an in-person clinical evaluation, as well as a clinical re-evaluation following any required conservative care as outlined throughout the guideline.
- An in-person clinical evaluation that includes a complete relevant medical history, physical examination, appropriate laboratory studies and initial non-advanced imaging (e.g., plain radiographs) should have been completed after the current episode of symptoms began. The in-person clinical evaluation may be, at least, either the initial or the re-evaluation.
    - Prior to advanced imaging consideration, the results of plain x-rays performed after the current episode of symptoms started or changed need to be available to the provider that is requesting the advanced imaging.
- When necessary, a failed trial of provider directed conservative treatment following the initial clinical evaluation and non-advanced imaging may be required:
    - The trial of conservative care lasting at least six weeks in duration
    - A clinical re-evaluation or documentation of other meaningful contact (e.g., email, telephone, video consult) with the provider's office following the initial evaluation

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Details will be in the specific criteria sections throughout this publication regarding when conservative treatment is required.

Repeat, Serial or Multiple Studies

The need for repeat or serial advanced imaging, whether CT or MRI, should be considered carefully and may not be medically necessary. This includes serial imaging for surveillance of healing or recovery from musculoskeletal disease. In the majority of musculoskeletal conditions, the medical evidence (i.e., documentation) does not support the need for repeat imaging.

In hand and wrist advanced imaging, as well as in foot and ankle imaging, studies are frequently ordered of both areas. This is not medically necessary since wrist imaging will capture from above the wrist to the mid-metacarpal area, and ankle imaging will capture from above the ankle to the mid-metatarsal area. Only one CPT® code per area should be reported.

Health Equity Considerations

Health equity is the highest level of health for all people; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which people are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include safe housing, transportation, and neighborhoods; racism, discrimination and violence; education, job opportunities and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

Evidence Discussion (MS-1)

MS.GG.0001.0
v2.0.2026

Advanced imaging is typically not necessary for the initial evaluation of individuals with a musculoskeletal complaint. A diagnosis can often be made based on a detailed history, physical examination, appropriate laboratory tests and/or plain radiographs or initial ultrasound (US).[1-5] Many individual's complaints can improve within a few weeks to months with conservative care.

The American College of Radiology Appropriateness Criteria recommended that x-rays, or US in a few select scenarios, as the initial imaging modality for most musculoskeletal complaints.[1,3] These initial images can be helpful in determining if a course of conservative treatment is recommended. In some instances, the initial x-rays or US may help determine a diagnosis or that more advanced images or procedures are appropriate.[6] If conservative treatment is unsuccessful or more advanced study is needed the initial images can be helpful in determining the next course of action.[6,7] These initial images can be helpful in pre-operative planning when surgery is being considered.[1,3]

Advanced imaging can often demonstrate abnormalities that have no relevance to the patient's symptoms. Studies have shown that advanced imaging of asymptomatic middle age individuals commonly demonstrate musculoskeletal abnormalities that do not affect their quality of life.[8] Focusing on incidental findings can lead to overtreatment through unnecessary referral to medical specialists or unneeded medical procedures. Advanced imaging can have additional risks to the individual beyond those of initial plain images. There are risks associated with additional exposure to radiation. There can also be complications due to implantable devices or metallic foreign bodies in the individual. Risk mitigation needs to be weighed when advanced imaging is being considered, especially in relation to repeat or serial advanced imaging.[9]

In many instances for musculoskeletal complaints, current evidence has supported the recommendation of obtaining initial plain x-rays, or US when appropriate, and having the individual follow a course of provider directed conservative care prior to seeking advanced imaging studies.[1] The potential clinical benefit of starting conservative care and not needing advanced images or additional procedures may outweigh the potential harm of a brief delay of obtaining said imaging. It may also help to reduce the risk of unnecessary exposures to radiation/chemicals associated with the advanced imaging techniques.[7,9]

Imaging Techniques (MS-2)

MS.IM.0002.0
v2.0.2026

Plain Radiograph

Plain radiographs (x-ray) are often the initial imaging for musculoskeletal conditions. The results of plain x-rays performed after the current episode of symptoms started or changed need to be available to the provider requesting advanced imaging, unless otherwise noted, to rule out those situations that do not often require advanced imaging, such as: osteoarthritis, acute/healing fracture, dislocation, osteomyelitis and bone tumor amenable to biopsy or radiation therapy (in known metastatic disease). Unless otherwise noted in the guidelines, x-rays should be performed before requesting advanced imaging.

Magnetic Resonance Imaging

Magnetic resonance imaging (MRI) is often a preferred advanced imaging modality in MSK conditions because it can be superior in visualizing the soft tissues and physiological processes happening due to an injury or medical condition. As MRI uses magnetic fields, it does not expose the individual to ionizing radiation and may be a better choice when exposure is a concern. However, individuals with implanted devices may not be able to undergo MRI.

Currently there is inadequate scientific evidence to support the necessity of positional MRI (also referred to as dynamic, weight-bearing, standing or kinetic MRI) and delayed gadolinium enhanced MRI of cartilage (dGEMRIC). These imaging modalities should be considered not medically necessary.

Computed Tomography

Computed tomography (CT) is preferred for imaging cortical bone anatomy. It is useful for studying complex fractures, dislocations, and assessing delayed union or non-union of fractures when x-rays are equivocal. CT can also be the imaging choice in individuals who cannot undergo an MRI.

Positional CT (also referred to as weight-bearing or cone beam CT) may be useful in imaging of the foot and ankle. Requests for positional CT for the foot and ankle are subject to the same condition-specific criteria as contained throughout this guideline publication. Positional CT of anatomic areas other than the foot and ankle are considered not medically necessary.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Ultrasound

Ultrasound (US) uses sound waves to produce images that can be used to evaluate a variety of musculoskeletal disorders. US is highly operator dependent and proper training and experience are required to perform consistent, high-quality evaluations.

Nuclear Medicine

A bone scan is a nuclear medicine imaging study in which an amount of radioactive material is injected, and images are obtained at different time intervals, depending on the condition. A bone scan is done to reveal problems with bone metabolism. Areas where bone cells are repairing themselves show the most activity. It can help diagnose a number of bone conditions, including cancer of the bone or metastasis, location of bone inflammation, fracture, and bone infection.

Nuclear Medicine WBC Scan is performed using radioactive material which is tagged to the white blood cells. When injected into the body, the material attaches to sites of inflammation/infection. Once distributed in these areas, the sites of suspected infection/ inflammation can be seen on nuclear imaging equipment. These can be imaged as a planar study, SPECT study, or SPECT/CT study.

Bone Marrow Imaging is used in combination with a WBC Scan to help differentiate between true infection and physiological marrow uptake. The bone marrow scan provides a map of the normal physiological white cell uptake that is then compared to the white blood cell scan. Any discordance in white cell uptake (e.g., more WBC uptake than marrow uptake) between the two studies indicates a focus of infection.

Positron Emission Tomography

Positron Emission Tomography (PET/CT) is a nuclear medicine/CT fusion study that uses a positron emitting radiotracer to create cross-sectional and volumetric images based on tissue metabolism. PET/CT allows for better anatomic localization of the areas of abnormal increased tissue activity. PET/CT can be helpful for imaging certain musculoskeletal conditions when MRI or CT is equivocal or cannot be performed.

- See: **Nuclear Medicine (MS-28)** and condition specific guidelines for specific indications.

Contrast Issues

Most musculoskeletal imaging (MRI or CT) is completed without contrast media; however, contrast may be useful and will be indicated throughout the condition-specific criteria in these guidelines. Some examples may be tumors, osteomyelitis, infection, arthrograms, detection of rheumatoid arthritis. For individuals with contrast contraindication, the corresponding advanced imaging without contrast may be approved as an alternative. However, in some cases the non-contrast study may not

Click Here to Return to the Main TOC

3D Rendering (MS-3.1)

MS.TD.0003.1
v2.0.2026

3-D image post-processing of conventional images is medically necessary for preoperative planning when conventional imaging is insufficient for the following:

- Complex fractures (comminuted or displaced)/dislocations of any joint
- Spine fractures, pelvic/acetabulum fractures, intra-articular fractures.
- Preoperative planning for other complex surgical cases.

The code assignment for 3-D rendering depends upon whether the 3-D post-processing is performed on the scanner workstation (CPT® 76376) or on an independent workstation (CPT® 76377)

- 2-D reconstruction (i.e., reformatting axial images into the coronal plane) is considered part of the tomography procedure, is not separately reportable, and does not meet the definition of 3-D rendering.
- It is not medically necessary to report 3-D rendering in conjunction with CTA and MRA because those procedure codes already include the post-processing.
- In addition to the term "3-D," the following terms may also be used to describe 3-D post-processing:
  - Maximum intensity projection (MIP)
  - Shaded surface rendering
  - Volume rendering
- Additionally - If multiple CPT codes are performed for the same indication on the same day, one 3D rendering code is required. If they are performed on separate days, 3D rendering codes are required for each study on each day.
- The 3-D rendering codes require concurrent supervision of image post-processing 3-D manipulation of volumetric data set and image rendering.

Evidence Discussion (MS-3)

MS.TD.0003.0
v2.0.2026

In some complex clinical scenarios, initial and conventional advanced images alone may not sufficiently reveal bony displacement and other incongruities. Accurate radiographic characterization of complex fractures and injuries is important for appropriate treatment decisions. The American College of Radiology, in multiple of their Appropriateness Criteria (ACR) publications, supports the use of 3D image post-processing of conventional images of complex fractures and injuries when said images are insufficient to visualize bone displacement and/or incongruity, and further clarification will aid in treatment decisions. [1-3]

Evidence has shown that 3D modeling can improve the accuracy of fracture classification. In a cohort study comparing the use of 2D CT images alone or combined with 3D segmentation or 3D models, both trauma surgeons and residents were more accurate with their classification of proximal humerus fractures when they used digital 3D models.[4] In a systematic review, inter- and intra-observer agreement in proximal humeral fracture classification increased as image technology advanced from radiographs to 2D CT to 3D CT.[5] Fracture gaps of 100µm were identified at a consistent rate of 80-100% in CT images with displacements of up to 400µm visible in digital 3D models. However, rates were dependent on CT technology and post-processing effects of rendering, thus original CT images should still be used along with any 3D rendering for verification of fractures prior to surgery.[6]

In their Appropriateness Criteria for acute trauma to the hand and wrist, the ACR supports the use of 3D rendering as a visualization tool for more accurate preoperative planning in the management of some complex surgical procedures.[7] Additional evidence demonstrated the utility of 3D rendering in preoperative planning for various complex musculoskeletal conditions. In a retrospective study of the planning of reinforcement cages for total-hip replacement revision surgery 3D templating accurately predicted cage size in 29/27 surgeries, compared to only 15/27 using conventional 2D templating.[8] 3D preoperative planning for reverse total shoulder arthroplasty has been shown to result in minimal deviation of the procedure from the plan with high levels of agreement in screw angle, length and prosthetic component size.[9] In a comparison of 2D versus 3D preoperative planning in total hip arthroplasty, 3D templating was found to result in higher accuracy restoration of native joint mechanics.[10]

Nuclear Medicine (MS-28.1)

MS.NM.0028.1
v2.0.2026

As mentioned in General Guidelines (MS-1.0), results of plain x-rays after the current episode of symptoms started or changed must be available to the requesting provider, unless otherwise specified below, prior to advanced imaging. A trial of conservative care may also be required, as specified below.

NOTE: SPECT scan may be medically necessary for any of the same criteria for which a bone scan is medically necessary as listed in this section if:

- The request is for CPT® 78300 and CPT® 78803, then only CPT® 78803 is to be approved if medical necessity is established.
- The request is for CPT® 78305 or CPT® 78306 and CPT® 78803, then two CPT® codes may be approved if medical necessity is established.

Nuclear Medicine may be medically necessary in the evaluation of some musculoskeletal disorders, and other rare criteria as follows:

- Evaluation of suspected aseptic loosening of orthopedic prostheses when recent plain x-ray is nondiagnostic:
  - Bone scan (CPT® 78315) OR
  - Distribution Of Radiopharmaceutical Agent SPECT (CPT® 78803, or 78831) OR
  - Hybrid SPECT/CT (CPT® 78830)
  - Criteria for non-nuclear medicine imaging can be found in: **Joint Replacement Post-Operative Follow-Up (MS-16.1)**
- For detection of ischemic or infarcted regions in sickle cell disease:
  - Nuclear medicine bone marrow imaging (CPT® 78102, 78103, or 78104) OR
  - SPECT (CPT® 78803) OR
  - Hybrid SPECT/CT (CPT® 78830)
  - See also: **Modality General Considerations (PEDMS-1.3)**
- Evaluation of complex regional pain syndrome or reflex sympathetic dystrophy, after failure of six weeks provider-directed conservative treatment, including re-evaluation:
  - Triple phase bone scan (CPT® 78315)
  - Criteria for non-nuclear medicine imaging of CRPS of the foot can be found in: **General Pain (MS-32.1)**
- Evaluation of Paget's disease
  - Bone scan (CPT® codes: 78300, 78305, or 78306) OR
  - Distribution Of Radiopharmaceutical Agent SPECT (CPT® 78803) OR

- Hybrid SPECT/CT (CPT® 78830)
- Criteria for non-nuclear medicine imaging can be found in: **Bone Lesion (MS-10.2)**

- Suspected fractures
  - If the following criteria listed below (as also found in **Occult, Stress or Insufficiency Fracture or Reaction (MS-5.2)**) (**excluding peri-prosthetic fractures**) are met:
    - For suspected hip/femoral neck, tibia, pelvis/sacrum, tarsal navicular, proximal fifth metatarsal, or scaphoid occult/stress/insufficiency fractures, and suspected atypical femoral shaft fractures related to bisphosphonate use when ALL the following apply:
      - The initial evaluation, history, and physical exam fails to establish a definitive diagnosis AND
      - The initial plain x-ray findings are negative or equivocal
      - CT without contrast can be performed as an alternative to MRI for suspected occult/insufficiency fractures of the pelvis/hip and suspected atypical femoral shaft fractures related to bisphosphonate and suspected occult fractures of the scaphoid
    - Or for all other suspected occult/stress/insufficiency fractures when ANY of the following apply:
      - Initial plain x-rays obtained a minimum of 14 days after the onset of symptoms are non-diagnostic for fracture OR
      - Repeat plain x-rays remain non-diagnostic for fracture after a minimum of 10 days of provider-directed conservative treatment
      - For suspicion of shin splints, a 6-week trial of provider-directed conservative treatment, including clinical re-evaluation, is also required prior to requesting advanced imaging.
      - For stress reaction surveillance or "return to play" decisions, advanced imaging is not medically necessary regarding a stress reaction identified on an initial imaging study.
      - For stress fracture follow-up imaging for "return to play" evaluation at least 3 months after the initial imaging study.
  - **And MRI cannot be performed**, the following imaging is medically necessary:
    - Tc-99m bone scan whole-body (CPT® 78306) with SPECT of the area of interest (CPT® 78803) OR
    - Hybrid SPECT/CT (CPT® 78830) OR
    - Bone scan (CPT® 78315, 78305, or 78300)
  - **Or for peri-prosthetic fractures when MRI cannot be performed**, the following imaging is medically necessary:

Click Here to Return to the Main TOC

    - Tc-99m bone scan whole-body (CPT® 78306) with SPECT of the area of interest (CPT® 78803) OR
    - Hybrid SPECT/CT (CPT® 78830) OR
    - Bone scan (CPT® 78315, 78305, or 78300)
- Evaluation of suspected bone infection if MRI or CT cannot be done and when infection is multifocal, or when the infection is associated with orthopedic hardware or chronic bone alterations from trauma or surgery:
    - **Note** - For suspected infection following joint replacement, joint aspiration is the initial evaluation after plain x-ray for a painful joint replacement. Joint aspiration should be negative or inconclusive prior to requesting advanced imaging.
        - Criteria for non-nuclear medicine imaging regarding specific joints post-operative from replacement surgery can be found in: **Joint Replacement Post-Operative Follow-Up (MS-16.1)**
    - FDG PET/CT (CPT® 78815 for multifocal infection, or CPT® 78811 for unifocal/ limited area of interest) if MRI or CT is equivocal or cannot be done
        - At this time, FDG is the only indicated radiotracer for use with PET/CT in the imaging of musculoskeletal conditions
    - Bone scan (CPT® 78315, 78300, 78305, or 78306) OR
    - Distribution of radiopharmaceutical agent SPECT (CPT® 78803 or 78831) OR
    - Hybrid SPECT/CT (CPT® 78830 or 78832)
    - A labeled leukocyte scan (radiopharmaceutical inflammatory imaging - one of CPT® codes: 78800, 78801, 78802, or 78803) in concert with Tc-99m sulfur colloid marrow imaging (one of CPT® codes: 78102, 78103, or 78104)

Evidence Discussion (MS-28)

MS.NM.0028.0
v2.0.2026

Many musculoskeletal complaints can be diagnosed based on a detailed history, physical examination and initial x-rays. In more complex clinical situations, x-rays can be useful in determining whether advanced diagnostic imaging is needed and which specific advanced diagnostic imaging study is warranted. MRI or CT are typically the study of choice if x-rays are non-diagnostic or equivocal in evaluating musculoskeletal complaints. While nuclear medicine scans may demonstrate high sensitivity to certain diagnoses, the increased exposure to radiation must be considered in comparison to other advanced imaging options.[1,2]

The American College of Radiology (ACR) has recommended the use of MRI, when possible, as the next image after x-rays for investigation of suspected infection, stress fracture and post-surgical complications following joint replacement. MRI can be as sensitive as nuclear medicine scans but also considerably more specific, while creating less radiation exposure. However, there may be situations where MRI or CT are not available, contraindicated or image results would be unclear. [1, 3-7]

Implanted hardware, devices, or foreign objects may create image artifacts making diagnosis uncertain. In these situations, nuclear medicine scans may be the next best option in imaging. Practical planning to keep radiation exposure as low as possible must be taken into account.[2] Bone scans have been shown to be as sensitive to stress fracture as MRI, allowing earlier detection than may be shown on plain x-ray.[3] When an alternative imaging modality to other advanced imaging is necessary to evaluate suspected infection, bone scans have demonstrated high sensitivity to osteomyelitis. However, their specificity has been shown to be limited (45%), especially when there are other underlying conditions (e.g., arthritis), recent fracture, or recent surgery.[4,5] Bone scan may also have similar sensitivity and specificity as MRI when evaluating suspected complex regional pain syndrome, type 1 and may be useful to rule-out the diagnosis.[8]

Osteoarthritis (MS-12.1)

MS.OT.0012.1
v2.0.2026

As outlined in General Guidelines (MS-1.0), initial images and physical exam are required prior to requesting advanced imaging for further investigation and/or treatment planning of osteoarthritis. See specific details below regarding any requirements for conservative care prior to requesting advanced imaging.

Non-surgical and surgical treatment planning, other than joint replacement

- Osteoarthritis - CT without contrast for further investigation of osteoarthritis is medically necessary when ALL of the following apply:
  - Requested for treatment planning, AND
  - Congenital or significant atypical post-traumatic arthritic deformities are identified on plain x-ray, AND
  - The aforementioned deformities require further evaluation of their clinical significance, AND
  - The request is related to the shoulder, elbow, wrist, hip, knee, or ankle
- Reconstructive joint sparing/salvage surgery planning - MRI arthrogram or CT arthrogram for joint sparing/salvage reconstructive surgery planning is medically necessary for the following:
  - Suspected concomitant rotator cuff tear of the shoulder
  - Suspected concomitant labral tear of the shoulder or hip
  - Suspected concomitant internal derangement of the knee

Joint replacement planning, non-customized-to-patient (not for intra-operative navigation)

- **Elbow, wrist, hip, knee or ankle** - CT without contrast of the elbow (CPT® 73200), wrist (CPT® 73200), hip (CPT® 73700 or 72192), knee (CPT® 73700) or ankle (CPT® 73700) for non-customized-to-patient joint replacement planning (prior to surgery/not for intra-operative navigation) is medically necessary when ALL of the following apply:
  - Initial x-rays have been performed after the current episode of symptoms started or changed and results are available to the requesting provider AND
  - Congenital or significant atypical post-traumatic arthritic deformities are identified on plain x-ray AND
  - The aforementioned deformities require further evaluation of their clinical significance

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

- **Shoulder** - CT without contrast (CPT® 73200) and/or MRI without contrast (CPT® 73221) of the shoulder for non-customized-to-patient joint replacement planning (prior to surgery/not for intra-operative navigation) is medically necessary when ALL of the following apply:
  - Initial x-rays have been performed after the current episode of symptoms started or changed and results are available to the requesting provider

Joint replacement planning and intraoperative navigation, customized-to-patient

- CT without contrast or MRI without contrast of the **shoulder, elbow, wrist, hip, knee, or ankle** for customized-to-patient joint replacement surgery planning and intraoperative navigation (e.g., MAKOplasty) is medically necessary when ALL of the following apply:
  - Initial x-rays have been performed after the current episode of symptoms started or changed and results are available to the requesting provider AND
  - The joint replacement surgery has been approved or does not require prior authorization
- The preoperative imaging listed above is considered not medically necessary if any of the following are deemed not medically necessary, not a covered benefit, or experimental, investigational, or unproven by the health plan:
  - Joint replacement surgery
  - Customized-to-patient implant
  - Computer assisted surgical navigation (e.g. MAKOplasty)
- See: Unlisted **Procedures/Therapy Treatment Planning (Preface-4.3)** in the Preface Imaging Guidelines

Inflammatory Arthritis (MS-12.2)

MS.OT.0012.2
v2.0.2026

As outlined in General Guidelines (MS-1.0), initial images and physical exam are required prior to requesting advanced imaging for further investigation and/or treatment planning of inflammatory arthritis (e.g., Gout, Pseudogout, Pigmented Synovitis, Rheumatoid arthritis).

Gout/Pseudogout

CT without contrast, MRI without contrast, or MRI without and with contrast of the area of interest is medically necessary for investigation of suspected gout/pseudogout when ALL of the following are met:

- Initial plain x-ray to rule out other potential disease processes
- Infection or neoplasm is in the differential diagnosis for soft-tissue tophi

Pigmented Villonodual Synovitis (PVNS)

Results of plain x-rays performed after the current episode of symptoms started or changed need to be available to the requesting provider prior to requesting advanced imaging for PVNS

MRI without contrast of the affected joint, or CT with contrast if MRI contraindicated, is medically necessary for the investigation of PVNS following plain x-rays.

Rheumatoid Arthritis

Plain x-ray, physical exam, and appropriate laboratory studies are required prior to advanced imaging for rheumatoid arthritis

- Results of plain x-rays performed after the current episode of symptoms started or changed need to be available to the requesting provider
- Examples of appropriate laboratory studies may include: Lyme titers, rheumatoid factor (RF), anti-cyclic citrullinated peptide (anti-CCP), sedimentation rate (ESR), C-reactive protein (CRP), and antinuclear antibody (ANA), joint fluid analysis

US (CPT® 76881 or CPT® 76882), MRI without contrast OR MRI without and with contrast is medically necessary for investigation of rheumatoid arthritis in the most symptomatic joint, or of the dominant hand or wrist, in ALL of the following situations:

- When diagnosis is uncertain prior to initiation of drug therapy
- To study the effects of treatment with disease modifying anti-rheumatic drug (DMARD) therapy

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- To identify seronegative RA individuals that might benefit from early DMARD therapy
- To determine change in treatment, such as:
  - Switching from standard DMARD therapy to tumor necrosis factor (TNF) therapy.
  - Changing to a different TNF drug therapy, then one MRI (contrast as requested) of a single joint can be performed.
  - Addition of other treatments, including joint injections
- MRI or US is not medically necessary for routine follow-up of treatment

Evidence Discussion (MS-12)

MS.OT.0012.0
v2.0.2026

Current ACR appropriateness criteria for chronic pain in the shoulder, knee, and hip all recommended plain x-ray as the initial image of choice when investigating suspected osteoarthritis (OA).[1-3] Advanced imaging is typically not necessary for the initial evaluation of OA, a diagnosis can be made based on history, physical exam and plain x-rays.[4] For most individuals diagnosed with OA, treatment does not rely on advanced imaging findings, and many can improve with conservative care.[5-8]

When individuals with OA poorly respond to conservative care or there is a concern for concomitant joint pathology, advanced imaging may be able to identify additional sources of symptoms.[9] MRI is generally considered the next appropriate imaging study for chronic joint pain when x-rays are inconclusive or further investigation is warranted. CT may be appropriate in specific situations to provide additional bony detail for treatment planning or when MRI is contraindicated.[1-3]

Plain x-rays are typically sufficient for preoperative planning for the majority of patients undergoing joint replacement surgery. However, for those with congenital or significant atypical post-traumatic arthritic deformities, CT scan can be of value for further evaluation/planning.[10] Advanced imaging will also be required prior to the replacement surgery if there will be the use of custom implants, patient specific instrumentation or computer assisted navigation.[11]

The American College of Radiology (ACR) Appropriateness Criteria for Chronic Extremity Joint Pain-Suspected Inflammatory Arthritis, Crystalline Arthritis, or Erosive Osteoarthritis (revised 2022) has recommended plain radiography as the initial imaging study for chronic extremity joint pain where crystalline arthritis is suspected.[12] X-ray sensitivity can be lower than other imaging modalities, however they may contain sufficient findings for the diagnosis of gout or calcium pyrophosphate deposition disease (CPPD). The benefits to using x-rays as an initial imaging study is to potentially avoid the need for further testing, treatment delays. Early onset gout/pseudogout may not be evident on any imaging, so reliance on a complete clinical history, evaluation and synovial fluid testing is important in any initial examination when gout/pseudogout is suspected.[13]

Advanced imaging is typically not required for the evaluation of patients with suspected crystalline arthropathy. The presence of monosodium urate crystals or calcium pyrophosphate crystals on synovial fluid microscopy can be definitive of a diagnosis of gout. However, additional imaging can be helpful in the evaluation of an individual's symptoms when differential diagnoses are suspected.[13]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Significant advances in imaging have made the visualization of gout/pseudogout much better than in previous years, especially when using US and CT technology. The 2018 EULAR recommendations stated that US offers the best potential for diagnosis of gout and dual-energy CT is showing great promise in its utility when compared to other imaging options.[13] Research since those recommendations have added more support that US and dual-energy CT are modalities of choice. A small cross-sectional study demonstrated that US is more specific in detecting early stage gout and that both US and CT have similar accuracy for middle and late stage disease identification.[14] A systematic review in 2022 of 28 studies determined that the sensitivity and specificity for US to detect gout was 84% and 84% respectively for both early and late staged, and for dual-energy CT to be 89% and 91% for chronic gout (75% and 85% for earlier staged disease).[15] A 2019 meta-analysis found that dual-energy CT was only less sensitive for as early as 6 weeks since the start of symptoms.[16] In 2018, two systematic reviews analyzing the accuracy of and comparing dual energy CT other imaging modalities concluded it was better than x-ray or normal CT and equal to US in diagnosing gout.[17,18] There is limited evidence to lend any support of the utility of other advanced image options in the investigation of gout/pseudogout. The most recent ACR recommended that CT with contrast or MRI of any method are usually not appropriate when investigating gout/pseudogout.[12] The 2018 EULAR recommendations are similar, that while MRI has some ability to detect crystalline deposit there is limited research in the diagnostic utility of the images, especially when compared to other imaging options.[13] The utility of MRI may change as research and technology continue to advance.

The ACR Appropriateness Criteria for Chronic Extremity Joint Pain-Suspected Inflammatory Arthritis, Crystalline Arthritis, or Erosive Osteoarthritis (revised 2022) recommended plain radiography as the initial imaging study for chronic extremity joint pain where Rheumatoid arthritis (RA) is suspect.[12] Clinical and laboratory assessment of RA remains the cornerstone of diagnosis and determining a response to treatment.[19] Inconclusive or non-diagnostic imaging results can be further evaluated with advanced imaging. MRI allows assessment of all structures as well as bone edema and baseline bone edema on low and high field MRI in patients with early RA is predictive of future radiographic damage.[20] Joints and bones in the hand are often affected in RA and assessing changes in these joints can help in therapy monitoring.[21] MRI and US play important roles in detecting subclinical disease in patients with inflammatory arthritis. These modalities have higher sensitivity in detecting subclinical synovitis, tenosynovitis, osteitis, and early erosive disease compared with physical exam and xray, therefore useful in early diagnosis and evaluating response to treatment.[22]

Investigation of Pigmented Villonodular Synovitis (PVNS) may be further aided with advanced imaging. Radiographs are non-specific and may appear normal 20% of the time but joint effusion, soft-tissue swelling, extrinsic erosion of bone, absence of calcification, preservation of joint space, and/or normal bone mineralization may be seen

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

in diffuse intraarticular PVNS. Localized form my appear normal on plain radiographs.[23] MRI may be necessary for diagnosis.[24] A retrospective review of 122 histologically confirmed PVNS cases demonstrated that MRI was helpful in obtaining a correct diagnosis 83% of the time.[25] MRI is also optimal for demonstrating the relationship of extraarticular lesions to the tendon sheath to suggest the diagnosis.[23]

Capsular/Synovial and Meniscal Dysfunction (MS-29.1)

MS.CS.0029.1
v2.0.2026

As outlined in General Guidelines (MS-1.0), initial images and physical exam are required prior to requesting advanced imaging for further investigation and/or treatment planning for capsular and/or synovial dysfunction. See specific details below regarding any requirements for conservative care prior to requesting advanced imaging.

- Initial plain x-ray imaging of the suspected area must first be performed after the current episode of symptoms started or changed and results available to the requesting provider.
- Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started, **EXCEPT** as noted below

When the above criteria has been met, the following advanced imaging is medically necessary:

- **Shoulder**
  - Labral tear or dysfunction (e.g. SLAP, ALPSA, HAGL) – CT with contrast (CPT®73201), MRI without contrast (CPT®73221), or MRI with contrast (CPT®73222).
  - Adhesive capsulitis (frozen shoulder) – MRI without contrast (CPT®73221)
- **Hip**
  - Labral tear or dysfunction - CT with contrast (CPT® 73701), MRI without contrast (CPT® 73721), or MRI with contrast (CPT® 73722)
- **Knee**
  - Hemarthrosis, non-traumatic or spontaneous – MRI without contrast (CPT® 73721)
    - **trial of conservative care not required**
  - Hemarthrosis, traumatic – see specific section related to the tissue trauma (e.g., fracture, joint stability, ligament, osteochondral injury, etc)
  - Meniscus tear - MRI without contrast (CPT® 73721), or CT with contrast (CPT® 73701) if MRI cannot be performed, is medically necessary for further investigation of suspected meniscal tear when all of the following have been met:
    - Plain x-rays have been performed after the beginning of the current episode of symptoms started

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started OR at least 2 of the following 4 criteria met:
  - positive McMurray's, Thessaly, or Apley's compression test
  - twisting or acute injury of the knee
  - locked knee: inability to fully extend knee on exam in comparison to the opposite knee
  - knee effusion
- For degenerative meniscal tear - MRI without contrast (CPT® 73721) is medically necessary for further investigation of suspected degenerative meniscus tear in an individual with osteoarthritis when all of the following have been met:
  - Plain x-rays have been performed after the beginning of the current episode of symptoms started
  - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started

◦ Synovial Plica or Medial Shelf – MRI without contrast (CPT® 73721)

Evidence Discussion (MS-29)

MS.CS.0029.0
v2.0.2026

Advanced imaging of synovial joint symptoms is typically not recommended as an initial diagnostic study. Research has demonstrated that asymptomatic individuals may commonly have tears or other findings on advanced images of capsular and synovial tissues (e.g., labrum, capsule, synovial lining).[1,2] Abnormal findings could lead to a cascade of unnecessary treatment or even surgery as asymptomatic tissues typically do not require any treatment. The American College of Radiology (ACR) Appropriateness criteria recommended that plain x-ray is the initial imaging study for investigation of joint pain.[3-6] When initial x-rays are inconclusive or conservative care does not result in amelioration more advanced images may be necessary.

Both CT and MRI technology, when necessary, may be useful for further investigation of labral tear at either the shoulder or hip. MR arthrography is considered the standard for labral imaging due to its high sensitivity and improved soft tissue contrast. However, there may be times, such as with acute trauma, effusion and pain, that MRI without contrast is preferred.[3,5] MRI without contrast can show if capsular thickening is present in the investigation of suspected adhesive capsulitis at the shoulder. It has a relatively high sensitivity for detection of adhesive capsulitis. The introduction of contrast fluid within the rotator interval or along the axillary recess can create limitations in detecting findings of adhesive capsulitis, for this reason MRA is not recommended as next imaging when investigating adhesive capsulitis.[4]

When additional investigation of knee pain is appropriate following initial x-rays and possible conservative care, MRI without contrast is the recommended next image for suspicion of capsular or synovial pathology. MRI has been demonstrated to show the presence of medial plica.[6] Further evaluation of suspected hemarthrosis may involve the use of advanced imaging to help identify the cause of bleeding, especially in recurring cases.[7,8]

Foreign and Loose Bodies (MS-6.1)

MS.FB.0006.1
v2.0.2026

As outlined in General Guidelines (MS-1.0), initial images and physical exam are required prior to requesting advanced imaging for further investigation and/or treatment planning.

Foreign Body

US (CPT® 76881 or CPT® 76882), CT without contrast or MRI without contrast or MRI without and with contrast for further investigation of foreign bodies is medically necessary after plain x-rays have ruled out the presence of radiopaque foreign bodies as follows:

- US is the preferred imaging for radiolucent foreign bodies (e.g., wood, plastic)
- CT without contrast is recommended when plain x-rays are negative and a radiopaque foreign body is still suspected
- MRI without and with contrast is an alternative to US and CT for assessing the extent of infection associated with a suspected foreign body

Loose Body

When the initial x-rays have been taken and the results are available to the provider, advanced imaging of symptomatic loose bodies in a joint is medically necessary as follows:

- **Shoulder** - MRI without contrast (CPT®73221)
- **Elbow** - CT without contrast (CPT® 73200) , CT with contrast (CPT® 73201), MRI without contrast (CPT® 73221) or MRI with contrast (CPT® 73222)
- **Hip** - MRI without contrast (CPT® 73721)
- **Knee** - MRI without contrast (CPT® 73721) or CT Knee with contrast (arthrogram) (CPT® 73701) if MRI cannot be performed
- **Ankle** - MRI without contrast (CPT® 73721)

Evidence Discussion (MS-6)

MS.FB.0006.0
v2.0.2026

Initial x-rays are recommended as a first imaging examination following acute trauma or when evaluating infection of the musculoskeletal system and there is suspicion of foreign objects or loose bodies.[1-3] X-rays are highly sensitive to embedded radiopaque materials, especially metals. X-rays provide an excellent overview of the anatomic area of interest allowing for a better overall assessment of symptoms.[4]

When a foreign body is not visualized on x-rays, ultrasound may be helpful to further evaluation.[1-3] Ultrasound has high sensitivity and specificity in detecting radiolucent objects like wood, and plastic. It has also been demonstrated as useful in detecting glass and metal.[4-6] Ultrasound is widely available, accessible, and does not involve ionizing radiation. Ultrasound can also help to evaluate complications of foreign body such as infections and vascular or tendon injuries. Ultrasound does have limitations, such as, visualization will be limited to more superficial tissue depths and variability of the technology available during the assessment may limit image quality.[5,6]

More advanced imaging may be necessary when suspected bodies are out of the range of ultrasound or are not clearly visualized on x-ray and ultrasound. CT has been shown as useful in detecting wood, aluminum, copper and some glass.[5] MRI is recommended when there is suspicion of infection or soft tissue and osseous change in relation to a foreign or loose body.[3] MRI is better than CT in the assessment of infection, however it was found to be less sensitive to actually visualizing a foreign body. There may also be image artifacts on an MRI if there are metallic foreign bodies.[4,5]

Acute Fractures (MS-5.1)

MS.FX.0005.1
v2.0.2026

As outlined in General Guidelines (MS-1.0), initial images and physical exam are required prior to requesting advanced imaging for further investigation and/or treatment planning.

CT or MRI without contrast of the area of interest is medically necessary for the investigation of suspected acute complex fracture when ANY of the following apply:

- The initial plain x-ray findings demonstrate a complex (comminuted or displaced) fracture with or without dislocation
  - CT is preferred unless there is a known or suspected association of the fracture with neoplastic disease or other contraindication of CT imaging. If CT is contraindicated, then MRI without/with contrast is preferred
- Preoperative planning - Refer to **3D Rendering (MS-3.1)** for medical necessity criteria of 3D processing

For suspected Lisfranc (tarsometatarsal) fracture (with or without dislocation), CT or MRI without contrast of the foot is medically necessary for further investigation when the following apply:

- Initial plain x-rays have been obtained and results are available to the ordering provider
- For suspicion of Lisfranc dislocation, or ligament, injury (without fracture) see: J**oint Instability and Dysfunction (MS-30.1)** for dislocation or **Ligament and Fascia Injury (MS-31.1)** for ligament injury

For osteochondral fracture or osteochondral injury, see: **Osteochondral Lesions and Fractures (MS-13.1)**

Occult, Stress, Insufficiency Fracture or Reaction (MS-5.2)

MS.FX.0005.2
v2.0.2026

As outlined in General Guidelines (MS-1.0), initial images and physical exam are required prior to requesting advanced imaging for further investigation and/or treatment planning. See specific details below regarding any requirements for conservative care prior to requesting advanced imaging.

MRI without contrast is medically necessary for suspected **hip/femoral neck, tibia, pelvis/sacrum, tarsal navicular, proximal fifth metatarsal, or scaphoid** occult/stress/insufficiency fractures, and suspected **atypical femoral shaft** fractures **related to bisphosphonate use** when ALL of the following apply:

- The initial evaluation, history, and physical exam fails to establish a definitive diagnosis AND
- The initial plain x-ray findings are negative or equivocal
- CT without contrast can be performed as an alternative to MRI for suspected occult/insufficiency fractures of the pelvis/hip and suspected atypical femoral shaft fractures related to bisphosphonate and suspected occult fractures of the scaphoid

CT or MRI without contrast of the area is medically necessary for the investigation of all other suspected occult/stress/insufficiency fractures when ANY of the following apply, except as otherwise noted:

- Initial plain x-rays obtained a minimum of 14 days after the onset of symptoms are non-diagnostic for fracture OR
- Repeat plain x-rays remain non-diagnostic for fracture after a minimum of 10 days of provider-directed conservative treatment
- **For Tarsal navicular stress/occult fracture** - MRI Foot without contrast (CPT® 73718)
  - CT Foot without contrast (CPT® 73700) for follow-up of healing fractures
  - X-ray results are available to the requesting provider
- **Note** - When MRI cannot be performed to investigate suspected fractures see: **Nuclear Medicine (MS-28.1)**

MRI without contrast (CPT® 73718) is medically necessary for suspicion of shin splints when both of the following are met:

- Initial plain x-ray results are available to the requesting provider AND

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started

For **stress fracture follow-up** imaging for "return to play" evaluation at least 3 months after the initial imaging study, MRI without contrast of the area of interest is medically necessary

For **stress reaction surveillance** or "return to play" decisions, advanced imaging is not medically necessary regarding a stress reaction identified on an initial imaging study.

Periprosthetic fractures related to joint replacement see: **Joint Replacement Post-Operative Follow-Up (MS-16.1)**

Other Indications (e.g., Delayed Union, Preoperative) (MS-5.3)

MS.FX.0005.3
v2.0.2026

As outlined in General Guidelines (MS-1.0), initial images and physical exam are required prior to requesting advanced imaging for further investigation and/or treatment planning.

CT or MRI without contrast after recent (within 30 days) plain x-ray if ONE of the following is present:

- Concern for delayed union or non-union of fracture, osteotomy, or joint fusions
- Part of preoperative evaluation for a planned surgery of a complex fracture with or without dislocation

Proprietary Information of UnitedHealthcare.

Evidence Discussion (MS-5)

MS.FX.0005.0
v2.0.2026

It is widely accepted that the initial imaging for a patient with a suspected fracture should be plain radiographs. The American College of Radiology (ACR) has recommended plain x-ray as the initial image for a majority of both acute and chronic musculoskeletal pain situations, including suspected fractures.[1] When the initial x-rays are negative or unclear, yet fracture is still suspected the ACR has recommended CT as the next method of investigation as it can provide detailed information on bony structure and allow for further evaluation and treatment planning.[1] MRI may be an alternative image to CT in a situation where CT is contraindicated or there has been complex and/or extensive trauma and surrounding tissues also need to be evaluated.[2-4]

The American College of Radiology also recommended that x-rays should be the initial imaging for a suspected stress fracture. Initial x-rays may not identify the fracture and if there is continued suspicion repeat x-ray imaging in 10 - 14 days is supported.[5] Repeat radiographs may show osseous reaction confirming the presence of an occult or stress fracture. However, if repeat x-rays remain negative and there is still suspicion of an occult or stress fracture, MRI is recommended as it has been shown to be the most sensitive and specific imaging modality for workup of suspected stress injuries.[5,6] In addition, there exists a subset of occult/stress/insufficiency fractures that have an increased risk of fracture progression, delayed healing, non-union and avascular necrosis. For these high-risk injuries, advanced imaging is recommended if initial x-rays are negative or indeterminate as these injuries require early diagnosis and immediate treatment.[5,7,8]

The evaluation of patients with chronic stress syndromes (e.g., shin splints) includes a detailed history, physical examination and plain x-rays.[5] Many individuals can improve with conservative care. If the individual fails to respond to an adequate trial of conservative care, MRI is recommended as the next imaging option for further investigation.[9]

For the assessment of bony healing, serial x-ray imaging is usually sufficient. However, if there are still concerns for delayed union or non-union, CT scanning can provide detail as to the presence or absence of bridging callus. MRI can also assist in the evaluation of bone healing.

General Infection/Osteomyelitis (MS-9.1)

MS.OI.0009.1
v2.0.2026

As outlined in General Guidelines (MS-1.0), initial images and physical exam are required prior to requesting advanced imaging for further investigation and/or treatment planning.

US (CPT® 76881 or CPT® 76882), MRI without contrast, MRI without and with contrast, CT without contrast, or CT with contrast of the affected area for further investigation of infection is medically necessary after plain x-ray(s) have been obtained in the following scenarios:

- Plain x-ray(s) do not demonstrate infection, AND
- Plain x-ray(s) do not suggest alternative diagnoses such as neuropathic arthropathy (see Charcot Joint (MS-9.2)) or fracture, AND
- Soft tissue or bone infection (osteomyelitis) is suspected

  OR
- Plain x-ray(s) are positive for infection, AND
- The extent of infection into the soft tissues and any skip lesions require evaluation

For Individuals with **diabetic foot infections** after plain x-rays - as a compliment to plain x-ray - MRI without and with contrast (CPT® 73720), MRI without contrast (CPT® 73718), CT without contrast (CPT® 73700) or CT with contrast (CPT® 73701)

For individuals with suspected spinal infections please use the spine imaging guidelines, see: **Red Flag Indications (SP-1.2)**

For nuclear medicine studies appropriate in specific scenarios, see: **Nuclear Medicine (MS-28)**

Charcot and Septic Joint (MS-9.2)

MS.OI.0009.2
v2.0.2026

As outlined in General Guidelines (MS-1.0), initial images and physical exam are required prior to requesting advanced imaging for further investigation and/or treatment planning. See specific details below regarding any requirements for conservative care prior to requesting advanced imaging.

Charcot Joint

Following the initial x-ray and the failure of the required 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started, the following advanced imaging is medically necessary for the investigation of suspected Charcot joint:

- Charcot ankle - MRI without contrast (CPT® 73721)
- Charcot foot - MRI without contrast (CPT® 73718) or MRI without and with contrast (CPT® 73720)

Septic Joint

MRI without and with contrast, MRI without contrast, CT without contrast, CT with contrast, or Ultrasound (CPT® 76881 or CPT® 76882) of the affected joint for further investigation of joint sepsis is medically necessary when **standard or image-guided arthrocentesis is contraindicated, unsuccessful, or non-diagnostic**, and the clinical documentation satisfies ALL of the following criteria:

- History and physical examination findings [One of the following]:
  - Development of an acutely hot and swollen joint (< 2 weeks)
  - Decreased range of motion due to pain
  - Documented fever
- Laboratory tests [One of the following]:
  - Leukocytosis
  - Elevated ESR or C-reactive protein
  - Analysis of the joint fluid is non-diagnostic
- Plain x-ray of the joint - Results of plain x-rays performed after the current episode of symptoms started or changed need to be available to the requesting provider

MRI without and with contrast, MRI without contrast, CT without contrast, or CT with contrast of the affected joint to evaluate the extent of infection into the soft tissues and any skip lesions that would require evaluation is medically necessary after plain x-rays if

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

the arthrocentesis is diagnostic and if there is a confirmed septic joint. Results of plain x-rays performed after the current episode of symptoms started or changed need to be available to the requesting provider.

For the criteria for further investigation of post-operative joint replacement septic infection please see joint specific criteria in **Joint Replacement Post-Operative Follow-Up (MS-16.1)**

Evidence Discussion (MS-9)

MS.OI.0009.0
v2.0.2026

The American College of Radiology (ACR) has recommended that x-rays should be used for the initial evaluation of musculoskeletal infections, including osteomyelitis, septic arthritis, and soft tissue infection.[1] They also recommended x-rays as the initial image for the evaluation of feet in individuals with Diabetes Mellitus, which often present with symptoms consistent with infection.[2] Initial radiographs can provide an excellent overview of the anatomic area of interest and can help to exclude other causes of swelling or pain.[3] Radiographs can help with the interpretation of future imaging studies such as CT, MRI, US, and nuclear medicine scans.

The clinical presentation of a suspected infected area or joint has a wide differential diagnosis. Infection is primarily a clinical diagnosis based on physical examination and laboratory testing of blood and/or synovial fluid, which may require prompt arthrocentesis and culture.[3-5] In select situations when a full examination and initial imaging is unclear, advanced imaging may be necessary to better visual the extent of suspected infection and associated effusion or other tissue damage or injury.[3,4]

US, MRI, or CT can be appropriate as the next imaging study for suspected septic arthritis, soft tissue infection, or osteomyelitis following normal radiographs.[1,2] MRI is often the next image of choice for suspect musculoskeletal infection due to its superior contrast resolution of soft tissues which can be helpful in detecting the spread of infection.[3,4,6] They may also be helpful to evaluate the adjacent soft tissues for infection. MRI is also recommended as the next image for evaluation of suspected Charcot joint of the foot. Charcot joints often present with complex symptoms including infection and potential ulceration that may be best visualized with MRI.[2] US can be helpful in detecting effusion and for guiding aspiration for more superficial areas in question.[3,7] CT may also be appropriate in situations when MRI is contraindicated, such as in areas with implanted metal or suspected foreign metal, or MRI is unavailable.[3,4]

Joint Instability and Dysfunction (MS-30.1)

MS.IN.0030.1
v2.0.2026

As outlined in General Guidelines (MS-1.0), initial images and physical exam are required, **EXCEPT** for situations specifically listed as not required in this section, prior to requesting advanced imaging for further investigation and/or treatment planning. See specific details throughout the section regarding any requirements for when conservative care prior to requesting advanced imaging is required.

- Initial x-rays must have been performed after the current episode of symptoms started or changed and the results are available to the requesting provider

Advanced imaging for further investigation of joint instability and/or articular dysfunction is medically necessary as follows:

- **Shoulder**:
  - Glenohumeral dislocation/subluxation and/or Bankart or Hill-Sachs lesion – MRI with contrast (CPT®73222), MRI without contrast (CPT®73221), CT with contrast (CPT®73201) or CT without contrast (CPT®73200)
    - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required in individuals over age 40 with a first time dislocation
    - Conservative treatment is not required for individuals 40 years of age or younger with a first-time dislocation, and individuals with recurrent dislocations
  - Acromioclavicular dislocation/separation when ruling out possible rotator cuff tear – MRI without contrast (CPT® 73221)
  - Sternoclavicular (SC) dislocation/separation
    - **Initial x-rays are not required**
    - For evident or suspected SC dislocations - CT chest without contrast (CPT® 71250) or CT chest with contrast (CPT® 71260)
    - For differentiating physeal injury from SC dislocation in individuals 25 years of age or younger OR planning for operative repair - MRI chest without contrast (CPT® 71550) or MRI without and with contrast (CPT® 71552)
    - Proximal 1/3rd (one-third) clavicle fracture – CT chest with contrast (CPT® 71260), CT chest without contrast (CPT® 71250), MRI chest without contrast or MRI chest without and with contrast (CPT® 71552)
- **Wrist**:

- Distal Radioulnar joint instability – CT of both wrists, pronated and supinated positions, without contrast (CPT® 73200)

- **Pelvis**:
  - Osteitis Pubis/ Symphysis Pubis Diastasis – MRI without contrast (CPT® 72195)
    - Failure of 6 weeks of provider-directed conservative treatment, including re-evaluation, occurring after the current episode of symptoms started is required
- **Hip**:
  - Femoroacetabular Impingement, for preoperative planning – MRI without contrast (CPT® 73721) or MRI with contrast (CPT® 73722) and CT without contrast (CPT® 73700) or CT Pelvis without contrast (CPT® 72192)
    - Failure of 6 weeks of provider-directed conservative treatment, including re-evaluation, occurring after the current episode of symptoms started is required
- **Knee**:
  - Tibiofemoral dislocation following a significant trauma to evaluate for ligament and vascular injury – MRI without contrast (CPT® 73721) and/either MRA lower extremity without and with contrast (CPT® 73725) or CTA lower extremity without and with contrast (CPT® 73706)
  - Patellar dislocation/subluxation following an acute injury with consideration of surgery and concern for osteochondral fragment – MRI without contrast (CPT® 73721) or CT without contrast (CPT® 73700)
  - Recurrent Patellar instability if consideration for surgery – MRI without contrast (CPT® 73721) or CT without contrast (CPT® 73700)
    - Failure of 6 weeks of provider-directed conservative treatment, including re-evaluation, occurring after the current episode of symptoms started is required
- **Ankle**:
  - Impingement, anterior, anterior-lateral or posterior – MRI without contrast (CPT® 73721), MRI with contrast (CPT® 73722), or CT with contrast (CPT® 73701)
    - Failure of 6 weeks of provider-directed conservative treatment, including re-evaluation, occurring after the current episode of symptoms started is required
  - Instability, preoperative planning – MRI without contrast (CPT® 73721) or MRI with contrast (CPT® 73722)
    - Failure of 6 weeks of provider-directed conservative treatment, including re-evaluation, occurring after the current episode of symptoms started is required
- **Foot**:
  - Lisfranc (tarsometatarsal) dislocation - MRI Foot without contrast (CPT® 73718) or CT Foot without contrast (CPT® 73700)

Evidence Discussion (MS-30)

MS.IN.0030.0
v2.0.2026

The American College of Radiology (ACR) has recommended that x-rays be the initial image of choice for evaluation of acute and chronic joint instability symptoms (e.g., dislocation, subluxation) and articular dysfunction or abnormality (e.g., bony impingement, coalition).[1-6] X-rays, along with a full history and clinical examination, may be sufficient to determine a diagnosis and treatment plan. In many instances, having an individual follow a course of provider directed conservative care may be sufficient to reduce symptoms and aid in the return of normal function.[7,8]Early advanced imaging could expose individuals to unnecessary risks and additional healthcare costs.

Some acute injuries involving significant trauma may require advanced imaging prior to conservative care. Damage to surrounding anatomy can occur that would need prompt treatment. MRI is typically recommended as the next image for many acute joint injuries as it has excellent capability in discriminating soft tissues and surrounding anatomy. CT may also be appropriate when MRI is contraindicated, unavailable or better visualization of bony alignment is required, such as in surgical planning.[1,2,4,6,9]

When conservative care has not been effective at improving function, or an individual presents with re-occurring and chronic problems, both MRI and CT are recommended as next images to further investigate joint instability and dysfunction.[3,5,7,10] MRI is recommended as useful in assessing the integrity of tissues that support the joint (e.g., labrum, capsule, ligament) and damage that may have occurred over time to chondral surfaces of both the hip and shoulder.[7,10] MRI was shown to have good inter- and intra-rater reliability in assessing patellofemoral instability.[11]

Ligament and Fascia Injury (MS-31.1)

MS.LM.0031.1
v2.0.2026

As outlined in General Guidelines (MS-1.0), initial images and physical exam are required prior to requesting advanced imaging for further investigation and/or treatment planning. See specific details throughout the section regarding any requirements for when conservative care prior to requesting advanced imaging is required.

- Initial plain x-ray imaging of the suspected area must first be performed after the current episode of symptoms started or changed with results available to the requesting provider

Advanced imaging for further investigation of ligament and fascia injury is medically necessary as follows:

- **Elbow**
  - Ulnar Collateral Ligament tear, following acute or repetitive trauma (including overhead throwing athletes) – US (CPT® 76881 or CPT® 76882), MRI without contrast (CPT® 73221), MRI with contrast (CPT® 73222) or CT with contrast (CPT® 73201)
- **Wrist**
  - Intrinsic ligament tear and/or Triangular Fibrocartilage Complex injury – MRI with contrast (CPT® 73222) or CT with contrast (CPT® 73201).
    - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
- **Hand**
  - Ulnar Collateral Ligament tear, if ruling out a Stener lesion or a complete ligament tear – US (CPT® 76881 or CPT® 76882), or MRI without contrast (CPT® 73218)
- **Knee**
  - Cruciate and/or collateral ligament tear – MRI without contrast (CPT® 73721)
    - A failed trial of conservative treatment is not required if any of the following signs are positive in comparison to the opposite knee:
      - Anterior Drawer
      - Lachman
      - Pivot Shift
      - Posterior Drawer or Posterior Sag

    - Valgus Stress
    - Varus Stress
  - Otherwise, failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
- Patellofemoral and Patellotibial ligament tear – MRI without contrast (CPT® 73721)
  - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required

- **Ankle**
  - Lateral/Medial Ligament injury (e.g., sprained ankle), including avulsion fracture – MRI without contrast (CPT® 73721) or CT without contrast (CPT® 73700)
    - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
  - Syndesmosis Injury (e.g., high ankle sprain) – MRI without contrast (CPT® 73721) or CT without contrast (CPT® 73700)
- **Foot**
  - Lisfranc (tarsometatarsal) ligament injury - MRI Foot without contrast (CPT® 73718) or CT Foot without contrast (CPT® 73700)
    - For suspicion of Lisfranc dislocation injury or fracture (with out without dislocation) see: Joint Instability and Dysfunction (MS-30.1) for dislocation or Acute Fracture (MS-5.1) for fracture.
  - Plantar Fascia
    - Fascia tear (partial or complete) – US (CPT® 76881 or CPT® 76882), MRI without contrast (CPT® 73718)
      - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
    - Fasciitis preoperative planning – US (CPT® 76881 or CPT® 76882), MRI without contrast (CPT® 73718)
      - Failure of provider-directed conservative treatment lasting at least 6 months or more, including clinical re-evaluation, occurring after the current episode of symptoms started is required
    - Plantar plate (e.g., Turf Toe injury) – MRI without contrast (CPT® 73718)

Evidence Discussion (MS-31)

MS.LM.0031.0
v2.0.2026

Initial imaging of MSK injuries where ligament or fascia is suspected to be involved is typically done with plain x-rays. The American College of Radiology has recommended x-ray as the initial image for evaluation of most acute injuries.[1] Even in suspected ligament or fascia injury, initial x-rays can be beneficial in determining if there is damage or malalignment to bone that needs to be considered during a thorough evaluation.

A trial of conservative care following negative x-rays may be beneficial for some suspected ligament and fascia injuries prior to immediately seeking advanced imaging. Individuals that show improvement over time with conservative care could avoid the additional potential exposure and expense of advanced imaging or unnecessary treatment or surgery. In their 2018 revised Appropriateness Criteria for Acute Hand and Wrist Trauma, the ACR recommended that symptomatic individuals with negative initial x-rays may use a trial of immobilization and repeat x-rays.[2] Current injury rehabilitation guidelines have recommended that individuals with suspected lateral ankle sprains follow a 4-6 week conservative care program with advanced imaging only being performed for those with persistent symptoms despite following the whole program.[3] Furthermore, guidelines also indicate that individuals with suspected plantar fascial pain usually do not require imaging studies unless they fail a comprehensive conservative care program.[4]

When medically necessary, advanced imaging for ligament and fascia injury has demonstrated high accuracy. More superficial ligaments such as those in the hand, wrist and elbow may be appropriately visualized through ultrasound alone. Ultrasound has been shown to be 81% sensitive and 91% specific in detecting Ulnar collateral Ligament injury at the elbow and 96% sensitive and 90% specific at the thumb.[5-7] Ultrasound demonstrated high sensitivity in evaluating heel/foot pain and may have utility in ruling out plantar plate injury.[8]

When further imaging beyond initial x-ray or ultrasound is necessary to investigate potential ligament or fascia injury, MRI is typically considered the standard next image option. ACR recommendations for imaging of the acute elbow, wrist, hand, knee, ankle and chronic foot all support MRI as the next imaging type for ligament or fascia investigation. Due to MRI's sensitivity to different tissues, it can be useful in evaluating not only ligament and fascia, but also any associated stress injury to bone or marrow, edema patterns, syndesmotic injury, meniscal involvement or other soft tissue injury.[2,9-12] Having accurate imaging of all aspects of any injury will aid in appropriate management and treatment planning .

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

CT imaging may also be useful in some instances, such as if MRI is contraindicated for an individual or when evaluation of bone displacement is desired. When combined with contrast, CT can be helpful in more accurate visualization of malalignment of the small and compact joints of the wrist. CT arthrography has demonstrated sensitivity and specificity equal to, or higher than, MRI or arthroscopy in detection of scapholunate and lunotriquetral ligament injury.[2] CT imaging is supported in suspected "high-ankle" syndesmotic injury, while MRI is often still considered a better option, measurements from CT scans and displayed displacement have been demonstrated to identify syndesmotic injury seen on MRI.[12]

Limb Length Discrepancy (MS-17.1)

MS.LL.0017.1
v2.0.2026

A diagnostic advanced imaging CPT code (e.g., CPT® 73700, CPT® 73701, or CPT® 73702) is not medically necessary for the evaluation of limb length discrepancy.

Either plain radiograph or "CT scanogram," both reported with CPT® 77073, is appropriate to radiographically evaluate limb length discrepancy due to congenital anomalies, acquired deformities, growth plate (physeal injuries or surgery), or inborn errors of metabolism.

Evidence Discussion (MS-17)

MS.LL.0017.0
v2.0.2026

The findings of recent systematic reviews support that x-ray is the most valid and reliable method for evaluation of limb length discrepancy. Advanced imaging modalities are not supported in current research as a method to evaluate leg length discrepancy. These technologies are more expensive, can have added risks such as sedation, and increased exposure to radiation. Furthermore, they can have added time it takes an individual to access the technology and may be contraindicated for some that have implantable devices. Full length, anterior-to-posterior x-ray images are recommended. Studies also reported excellent reliability using CT scanogram imaging, which may be an appropriate alternative to x-rays.[1,2]

Muscle and Tendon Injuries (MS-11.1)

MS.MI.0011.1
v2.0.2026

As outlined in General Guidelines (MS-1.0), initial images and physical exam are required prior to requesting advanced imaging for further investigation and/or treatment planning. See specific details throughout the section regarding any requirements for when conservative care is required prior to requesting advanced imaging.

- Initial plain x-ray of the suspected area must first be obtained after the current episode of symptoms started or changed and results are available to the provider

Muscle belly strains/tears - Advanced imaging is not medically necessary. Advanced imaging will not change the treatment plan for muscle belly strains/tears. There is lack of evidence to support surgical treatment for these injuries. These injuries are nearly always treated through conservative, non-operative, care.

Tendons - Advanced imaging for further investigation of tendon injury and/or pathology is medically necessary as follows:

- MRI without contrast or US for imaging tendons not located in specific joints outlined below is medically necessary when either of the following apply:
  - Suspected partial tendon tear of a specific named tendon
  - Complete tendon tear of a specific named tendon for preoperative planning
- **Shoulder**
  - Impingement – US (CPT® 76881 or CPT® 76882), MRI without contrast (CPT®73221) or MRI with contrast (CPT®73222) or CT with contrast (CPT® 73201) if MRI is contraindicated
    - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
  - Chronic tendon inflammation/irritation (e.g., tendinitis, bursitis) – US (CPT® 76881 or CPT® 76882) or MRI without contrast (CPT®73221)
    - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
  - Bicep Tendon (Long Head), complete tear – US (CPT® 76881 or CPT® 76882) or MRI without contrast (CPT®73221)
    - Clinical exam must be inconclusive, or advanced imaging for preoperative planning/surgery is being considered

- Pectoralis Major/Minor complete tear – US (CPT® 76881 or CPT® 76882), MRI without contrast (CPT®73221) or MRI Chest without contrast (CPT®71550)
  - Clinical exam must be inconclusive or for preoperative planning
- Rotator Cuff tendon tear
  - Partial or complete tear from acute injury and surgery is being considered – MRI without contrast (CPT®73221), MRI with contrast (CPT®73222) or CT with contrast (CPT®73201)
  - Partial or complete tear – US (CPT® 76881 or CPT® 76882), MRI without contrast (CPT®73221) or MRI with contrast (CPT®73222) or CT with contrast (CPT®73201) if MRI is contraindicated
    - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
- Other tendon injury or pathology not otherwise specified above, partial or complete tear – US (CPT® 76881 or CPT® 76882) or MRI without contrast (CPT®73221)
  - Specific tendon must be named for partial tendon tear
  - Complete tears must be in relation to preoperative planning of a specific named tendon

- **Elbow**
  - Chronic tendon inflammation/irritation (e.g., tendinitis, bursitis)
    - Bursitis – US (CPT® 76881 or CPT® 76882), MRI without contrast (CPT® 73221) or MRI without and with contrast (CPT® 73223)
      - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
    - Tendinitis – US (CPT® 76881 or CPT® 76882) or MRI without contrast (CPT® 73221)
      - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
    - Epicondylitis, medial or lateral – US (CPT® 76881 or CPT® 76882) or MRI without contrast (CPT® 73221)
      - Symptoms must persist for longer than 6 months despite trial of at least 6 weeks of conservative treatment. Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required

Compartment Syndrome (MS-11.2)

MS.MI.0011.2
v2.0.2026

Acute - This is a surgical emergency and advanced imaging not medically necessary as this diagnosis is made clinically by direct measurement of muscle compartment pressure.

Chronic/Exertional - Advanced imaging should only be considered when ruling out other potential causes of extremity pain following a plain x-ray and conservative treatment as indicated. Results of plain x-rays performed after the current episode of symptoms started or changed need to be available to the requesting provider.

Evidence Discussion (MS-11)

MS.MI.0011.0
v2.0.2026

Initial evaluation of a patient with a suspected tendon injury should include an accurate history, careful examination and plain radiographs. The American College of Radiology has recommended x-ray as the initial image for evaluation of most acute and chronic injuries.[1] With negative x-rays, suspicion of tendon injury does not always require immediate advanced imaging. Best practice recommendations for MSK pain have stated that imaging be used selectively. Unnecessary imaging can drive up costs of care and may lead to over-medicalization of an individual's symptoms.[2,3] Many muscle and tendon injuries can significantly improve through conservative care without advanced imaging.

After x-rays have been done, and any conservative care recommended has not resulted in a meaningful improvement of symptoms, advanced imaging may be beneficial for further assessment and treatment planning of certain muscle and tendon injuries. Both US and MRI are supported by the American College of Radiology as a next appropriate image in the evaluation of acute and chronic shoulder, elbow, wrist, hip, knee, ankle and foot injuries when initial x-rays are negative or unclear and muscle or tendon involvement is suspected.[4-14] Evidence has shown that both US and MRI have been validated as excellent methods to evaluate the integrity of muscle and tendon, with MRI being reserved for instances of surgical planning, differential diagnosis or assessment of injury too deep for clear visualization by US.[15,16]

Advanced imaging will typically not change the treatment plan for muscle belly strains/ tears. These injuries are most often treated through conservative, non-operative, care. There is limited evidence to support the surgical repair of muscle belly strains/tears.[17]

Initial diagnosis of compartment syndrome is typically based on clinical presentation, perfusion pressure measurements and laboratory results. Acute compartment syndrome is considered a medical emergency for which a thorough clinical assessment and direct pressure measurements of the compartment can result in a diagnosis so the individual can quickly receive emergency care. Advanced imaging does not play a role in the diagnosis or management of this condition and may delay the time to surgical treatment.[18,19] Chronic exertional compartment syndrome can be determined through dynamic intra-compartmental pressure measurements. These are considered gold standard for diagnosis of chronic compartment pressure concerns. MRI has lacked validity as a non-invasive diagnostic tool for this condition. However, MRI may be useful to rule out other possible sources of pain if plain x-rays fail to find a source.[20,21]

Osteochondral Lesions and Fractures (MS-13.1)

MS.OC.0013.1
v2.0.2026

As outlined in General Guidelines (MS-1.0), initial images and physical exam are required prior to requesting advanced imaging for further investigation and/or treatment planning. The following must be met prior to requesting advanced imaging for further investigation and/or treatment planning of suspected osteochondral lesions or fractures (including osteochondritis dissecans):

- Initial plain x-ray imaging of the suspected area must first be performed after the current episode of symptoms started or changed
- If plain x-rays show a non-displaced osteochondral fragment, follow-up imaging should be with plain x-rays. Advanced imaging is not necessary

When the initial x-rays are negative and an osteochondral injury is still suspected or the x-rays and clinical examination suggest an unstable osteochondral injury the following advanced imaging is medically necessary:

- **Elbow** - MRI without contrast (CPT® 73221), MRI with contrast (CPT® 73222), CT without contrast (CPT® 73200) or CT with contrast (CPT® 73201)
- **Knee** MRI without contrast (CPT® 73721), MRI with contrast (CPT® 73722), or CT with contrast (CPT® 73701)
- **Ankle** - MRI without contrast (CPT® 73721) or CT without contrast (CPT® 73700)
- **Other Joints** - MRI without contrast, MRI with contrast (arthrogram), or CT with contrast (arthrogram)
- **Follow-up of healing (including post-operative fixation)** - MRI without contrast or CT without contrast when healing cannot be adequately assessed on follow-up plain x-rays.

Evidence Discussion (MS-13)

MS.OC.0013.0
v2.0.2026

The American College of Radiography (ACR) has recommended that x-ray should be the first imaging test performed to evaluate joint pain suspected to be due to chondral/ osteochondral lesions.[1-3] Open physes have a much higher potential for healing with conservative treatment. So, radiographs may help to exclude other causes of pain and to determine skeletal maturity, which significantly affects prognosis and management of Osteochondritis Dissecans lesions (OCD). Radiographs may also be sufficient for classification of lower grade lesions avoiding unnecessary advanced imaging.[4] In clinical practice, serial radiographs may be sufficient for monitoring healing of juvenile OCD lesions.

In individuals with radiographs positive for Osteochondritis Dissecans (OCD) or subchondral insufficiency fracture, or with negative radiographs but osteochondral fracture is still suspected, MRI may be medically necessary to further evaluate cartilage for additional injuries and for grading of osteochondral fractures and OCD.[1-3] MRI has a high diagnostic value for assessing the stability of lesions, especially in higher grade lesions.[4,5] This makes MRI useful in determining the best method of treatment, be that conservative or surgical.[4,6] Repeat MRI is suggested only if radiographs are not diagnostic for healing and for worsening symptoms.[6] CT without contrast may be medically necessary to evaluate patients with OCD to confirm loose bodies or when MRI is not definitive.[1-3] MR arthrography or CT arthrography is an effective test for locating intra-articular osteochondral fragments, loose bodies and grading chondral and osteochondral lesions. A combination of x-rays and MRI or CT is recommended to best evaluate the stability of lesions.[7]

Osteonecrosis/Avascular Necrosis (MS-4.1)

MS.AN.0004.1
v2.0.2026

As outlined in General Guidelines (MS-1.0), initial images and physical exam are required prior to requesting advanced imaging for further investigation and/or treatment planning. The following must be met prior to requesting advanced imaging for further investigation and/or treatment planning of suspected osteonecrosis (avascular necrosis):

- Initial plain x-ray imaging of the suspected area must first be performed after the current episode of symptoms started or changed

When the initial x-rays are negative or equivocal and the clinical symptoms warrant further investigation of osteonecrosis the following advanced imaging is medically necessary:

- MRI without contrast, MRI without and with contrast, or CT without contrast of the area of interest

When the initial x-rays have confirmed osteonecrosis and advanced imaging is needed for further treatment planning the following advanced imaging is medically necessary for the follow situations:

- Shoulder - Humeral head - MRI without contrast (CPT® 73221) or CT without contrast (CPT® 73200)
- Wrist – Lunate/Scaphoid - MRI without contrast (CPT® 73221) or CT without contrast (CPT® 73200)
- Hip – Femoral head - MRI without contrast (CPT® 73721) or CT without contrast (CPT® 73700)
- Knee – Distal Femur - MRI without contrast (CPT® 73721) or CT without contrast (CPT® 73700)
- Ankle – Talus - MRI without contrast (CPT® 73721) or CT without contrast (CPT® 73700)
- Foot – Tarsal Navicular/Metatarsal head - MRI without contrast (CPT® 73718) or CT without contrast (CPT® 73700)

Individuals with acute lymphoblastic leukemia and known or suspected osteonecrosis should be imaged according to guidelines in **Acute Lymphoblastic Leukemia (PEDONC-3.2)** in the Pediatric and Special Populations Oncology Imaging Guidelines.

Evidence Discussion (MS-4)

MS.AN.0004.0
v2.0.2026

The American College of Radiology Appropriateness Criteria (ACR) for Osteonecrosis (revised 2022) has recommended radiography as the initial imaging study for clinically suspected osteonecrosis. Radiographs are less sensitive for detection of early osteonecrosis but they help to exclude other causes of extremity pain such as fracture, primary arthritis, or tumor. In late stage osteonecrosis, x-rays will also show findings of secondary osteoarthritis.[1,2]When x-rays are negative or equivocal, and osteonecrosis is still suspected, the ACR supports the use of advanced imaging to aid in further diagnosis and treatment planning.[1]

Both CT and MRI are recommended as next step imaging options after plain x-rays are obtained. MRI has been shown to be both highly sensitive and specific to the detection of osteonecrosis. A 2018 meta-analysis demonstrated that MRI was 93% sensitive and 91% specific in the early detection of osteonecrosis of the femoral head.[3] A recent Delphi model to better predict femoral head collapse identified subchondral fracture as a key predictor. CT scans can provide important insights into the structural integrity of subchondral bone allowing for better treatment planning for patients with osteonecrosis.[4] Preoperative CT has been shown to more clearly display the extent of articular collapse than radiographs.[5] Both MRI and CT have been shown to have similar accuracy in displaying femoral head lesions in more advanced stages of osteonecrosis (ARCO stage III or greater).[6]

Osteoporosis (MS-14.1)

MS.OP.0014.1
v2.0.2026

Initial plain x-ray imaging is not required to request advanced imaging for osteoporosis screening.

Quantitative CT (CPT® 77078) can be approved for **screening** when DXA scanner is unavailable or known to be inaccurate for ANY of the following populations:

- Women 65 years of age or older, Men 70 years of age or older
- Women less than 65 years of age who have the following additional risk factors for osteoporosis:
  - Estrogen deficiency
  - A history of maternal hip fracture that occurred after age 50 years
  - Low body mass (less than 127 lb or 57.6 kg)
  - History of amenorrhea (greater than 1 year before age 42 years)
- Women less than 65 years or men less than 70 years of age who have the following additional risk factors:
  - Current use of cigarettes
  - Loss of height, thoracic kyphosis
- Individuals of any age with the following:
  - Bone mass osteopenia or fragility fractures on imaging studies such as x-rays, CT, or MRI
  - Develop 1 or more insufficiency fractures
- Individuals 50 years of age and older who develop a wrist, hip, spine, or proximal humerus fracture with minimal or no trauma, excluding pathologic fractures.
- Premenopausal females, or males age 20 to 50 years, with risk factors known to potentially alter bone mineral density such as:
  - Chronic renal failure
  - Rheumatoid or other inflammatory arthritis
  - Eating disorders, including anorexia nervosa and bulimia
  - Organ transplantation
  - Prolonged immobilization
  - Conditions associated with secondary osteoporosis, such as gastrointestinal malabsorption or malnutrition, sprue, osteomalacia, vitamin D deficiency, endometriosis, acromegaly, chronic alcoholism or established cirrhosis, and multiple myeloma

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Individuals who have had gastric bypass for obesity
  - Individuals with an endocrine disorder known to adversely affect bone mineral density (e.g., hyperparathyroidism, hyperthyroidism, or Cushing syndrome)
- Individuals receiving (or expected to receive) glucocorticoid therapy for >3 months
- Hypogonadal men older than 18 years of age and men with surgically or chemotherapeutically-induced castration
- Individuals beginning or receiving long-term therapy with medications known to adversely affect BMD (e.g., anti-convulsant drugs, androgen deprivation therapy, aromatase inhibitor therapy, or chronic heparin)

NOTE: Repeat screening quantitative computed tomography (QCT) can be approved no sooner than every two years.

Quantitative CT scan (CPT® 77078) can be approved for **monitoring/non-screening** when DXA scanner is unavailable or known to be inaccurate for ANY of the following circumstances:

- Follow-up in cases where QCT was the original study
- Multiple healed vertebral compression fractures
- Significant scoliosis
- Advanced arthritis of the spine due to increased cortical sclerosis often with large marginal osteophytes
- Obese individual over the weight limit of the dual-energy x-ray absorptiometry (DXA) exam table
- Individuals with BMI >35kg/m2
- Extremes in body height (i.e., very large and very small individuals)
- Individuals with extensive degenerative disease of the spine
- A clinical scenario that requires sensitivity to small changes in trabecular bone density (parathyroid hormone and glucocorticoid treatment monitoring).

NOTE: Repeat monitoring/non-screening QCT can be approved no earlier than one year following a change in treatment regimen, and only when the results will directly impact a treatment decision.

Evidence Discussion (MS-14)

MS.OP.0014.0
v2.0.2026

The primary diagnostic test used to screen for osteoporosis is the central dual x-ray absorptiometry (DEXA) which accurately measures bone mineral density at the hip and lumbar spine. DEXA accuracy and reproducibility has led to the established standards for diagnosis of osteoporosis by the World Health Organization.[1] The USA Bone Health and Osteoporosis Foundation has recommended bone mineral density testing in all women age 65 and older and all men age 70 and older, and in postmenopausal women younger than 65 years and men aged 50-69 years based on their risk factor profile, including if they had a fracture as an adult.[2] The American College of Radiology Appropriateness Criteria supports DEXA as the primary diagnostic choice to screen women >65 years of age and men >70 years of age for osteoporosis, and for postmenopausal women <65 years of age with additional risk factors for fracture.[3] Repeat bone mineral density assessments one to two years after initiating medical therapy for osteoporosis and every two years thereafter, but recognizes that testing more frequently may be warranted in certain clinical situations, and may be needed less frequently in patients without major risk factors or significant bone density loss on initial BMD testing. DEXA is currently the preferred method for monitoring treatment response.[2]

Quantitative CT (QCT) is regarded as a secondary tool after DEXA for screening for osteoporosis. QCT is highly accurate in determining tissue density within a region of interest. Indications for QCT are the same as for DEXA, however DEXA is recommended as the first-line screening and follow-up test for bone density. If DXA is not available, QCT may be used as a secondary technique and for serial/follow-up purposes.[2,3,4] Selected conditions in which QCT is considered superior to DEXA include extremes in body height, BMI >35, clinical scenarios when an increased sensitivity to small changes in trabecular bone density is required, and in patients with advanced degenerative bony changes in the spine.[3] A potential harm of Quantitative CT is increased radiation exposure (1-10 mSv) as compared to <0.1 mSv for DEXA scan. Whereas the radiation dose for both lumbar spine and hip scanning in a DEXA scan is approximately equivalent to that of a chest x-ray.

There is insufficient evidence to support the use of x-ray as a screening tool in patients suspected of having low bone mineral density. Patients whose x-rays report osteopenia and/or fragility fractures should be referred for DEXA for further characterization of bone density. There is also insufficient evidence to support the current use of quantitative ultrasound as a screening tool in patients suspected of having low bone mineral density.[3]

General Pain (MS-32.1)

MS.PN.0032.1
v2.0.2026

As outlined in General Guidelines (MS-1.0), initial images and physical exam are required prior to requesting advanced imaging for further investigation and/or treatment planning. See specific details throughout the section regarding any requirements for when conservative care prior to requesting advanced imaging is required. The criteria in this section applies only to general musculoskeletal pain conditions not already specified in any other section of this guideline.

- Initial plain x-ray imaging of the suspected area must first be performed after the current episode of symptoms started or changed and results are available to the requesting provider

Advanced imaging for further investigation of general musculoskeletal pain is medically necessary as follows:

- **Shoulder** - US (CPT® 76881 or CPT® 76882), MRI without contrast (CPT®73221) or CT with contrast (CPT® 73201) if MRI contraindicated
  - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
- **Elbow** - US (CPT® 76881 or CPT® 76882) or MRI without contrast (CPT® 73221)
  - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
- **Wrist** - US (CPT® 76881 or CPT® 76882), MRI without contrast (CPT® 73221), MRI with contrast (CPT® 73222), CT without contrast (CPT® 73200) or CT with contrast (CPT® 73201)
  - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
- **Hand** - US (CPT® 76881 or CPT® 76882), MRI without contrast (CPT® 73218) or MRI without and with contrast (CPT® 73220)
  - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
- **Pelvis** - MRI without contrast (CPT® 72195) or MRI right and/or left Hip without contrast (CPT® 73721)
  - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

  - Imaging for Sacroiliac and Coccygeal pain is guided by the Spine Imaging Guidelines (Sacroiliac Joint Pain/Sacroiliitis (SP-10.1) and Coccydynia without Neurological Features (SP-5.2))
- **Hip** - US (CPT® 76881 or CPT® 76882) or MRI without contrast (CPT® 73721)
  - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
- **Knee** - US (CPT® 76881 or CPT® 76882) or MRI without contrast (CPT® 73721)
  - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
  - For patellofemoral pain or tracking issues where surgery is being considered - MRI without contrast (CPT® 73721) or CT without contrast (CPT® 73700)
    - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
- **Ankle** - US (CPT® 76881 or CPT® 76882) or MRI without contrast (CPT® 73721)
  - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started
- **Foot** - MRI without contrast (CPT® 73718)
  - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
  - For investigation of sesamoid disorders:
    - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
    - MRI without contrast (CPT® 73718) or CT without contrast (CPT® 73700) of the foot
  - For investigation of Complex Regional Pain Syndrome (CRPS) (Type 1) at the foot:
    - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
    - MRI Foot without contrast (CPT® 73718)
    - Criteria regarding nuclear medicine imaging of CRPS is found in: **Nuclear Medicine (MS-28)**

Evidence Discussion (MS-32)

MS.PN.0032.0
v2.0.2026

General, unspecific, musculoskeletal pain and trauma may not always present in a definitive manner. An individual may present with symptoms similar to multiple differential diagnoses. Imaging, as part of a comprehensive examination and assessment, can be useful in these situations to help rule-in or -out a certain diagnosis so as to develop a clinical course of action. The American College of Radiology (ACR) has recommended x-ray as the initial evaluation image for the vast majority of non-specific acute[1-7] and chronic[8-14] musculoskeletal pain. Initial x-rays may provide sufficient information, along with the clinical evaluation, to form a diagnosis. These initial images can be helpful in determining if a course of conservative treatment is recommended. In some instances, the initial x-rays or US may help determine a diagnosis or that more advanced images or procedures are appropriate.[15]

Advanced imaging can often demonstrate abnormalities that have no relevance to the patient's symptoms. Studies have shown that advanced imaging may demonstrate musculoskeletal abnormalities that do not affect their quality of life.[16] Focusing on incidental findings can lead to overtreatment through unnecessary referral to medical specialists or unneeded medical procedures. Advanced imaging can have additional risks to the individual beyond those of initial plain images. There are risks associated with additional exposure to radiation. There can also be complications due to implantable devices or metallic foreign bodies in the individual. Risk mitigation needs to be weighed when advanced imaging is being considered, especially in relation to repeat or serial advanced imaging.[17,18] Musculoskeletal complaints may respond to care prior to needing advanced imaging. Current ACR guidance has recommended obtaining initial plain x-rays and having the individual follow a course of provider directed conservative care prior to seeking advanced imaging for many nonspecific complaints.[8-14] The potential clinical benefit of starting conservative care and not needing advanced images or additional procedures may outweigh the potential harm of a brief delay in obtaining said imaging.

MRI is commonly recommended as the next image technology of choice.[1-14] The use of contrast media during imaging will depend on the clinical presentation and the particular tissues suspected to be injured. When x-rays are negative and there is suspicion of soft tissue involvement MRI can be helpful to visualize tissue damage and effusion. CT may also be helpful in situations where MRI is contraindicated, or x-rays were unclear and bony involvement continues to be suspect.[1-14]

Joint Replacement Post-Operative Follow-Up (MS-16.1)

MS.PS.0016.1
v2.0.2026

As outlined in General Guidelines (MS-1.0), the following must be met prior to requesting advanced imaging for further investigation and/or treatment planning of joint replacement post-op symptoms (e.g., aseptic loosening, infection, fracture, pseudotumor, implant performance):

- Plain x-ray imaging of the suspected area must first be performed after the current post-operative episode of symptoms started with results available to the requesting provider
- See specific details throughout the section regarding any requirements for when conservative care prior to requesting advanced imaging is required
- For suspected periprosthetic infection - Joint aspiration culture is the initial evaluation after plain x-ray for a painful joint replacement when periprosthetic infection is suspected
- Criteria regarding any **nuclear medicine imaging** of suspected post-operative joint replacement complications (e.g., aseptic loosening, peri-prosthetic fracture, suspected infection) is found in: **Nuclear Medicine (MS-28)**

Advanced imaging for further investigation of joint replacement post-operative follow-up is medically necessary as follows:

- **Shoulder**:
  - Suspected aseptic loosening or fracture – US (CPT® 76881 or CPT® 76882), MRI without contrast (CPT® 73221), OR CT without contrast (CPT® 73200)
  - Suspected infection with negative or inconclusive aspiration culture – US (CPT® 76881 or CPT® 76882), MRI without contrast (CPT® 73321), MRI without and with contrast (CPT® 73223) OR CT with contrast (CPT® 73201)
  - Possible rotator cuff tear – US (CPT® 76881 or CPT® 76882), MRI without contrast (CPT® 73221) OR CT with contrast (CPT® 73201)
  - Possible nerve injury – US (CPT® 76881 or CPT® 76882) OR MRI without contrast (CPT® 73221)
- **Elbow/Wrist**:
  - Suspected aseptic loosening or fracture – CT without contrast (CPT® 73200)
  - Suspected infection with negative or inconclusive aspiration culture – US (CPT® 76881 or CPT® 76882), MRI without contrast (CPT® 73221), MRI without and with contrast (CPT® 73223) OR CT with contrast (CPT® 73201)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- **Hip**:
  - Suspected aseptic loosening or fracture – CT without contrast (CPT® 73700)
  - Suspected infection with negative or inconclusive aspiration culture – US (CPT® 76881 or CPT® 76882), MRI without contrast (CPT® 73721), MRI without and with contrast (CPT® 73723), CT with contrast (CPT® 73701), OR CT without contrast (CPT® 73700)
  - Suspected particle disease (aggressive granulomatosis) after infection has been excluded – MRI without contrast (CPT® 73721), OR CT without contrast (CPT® 73700)
  - Suspected periprosthetic fracture after non-diagnostic x-ray – CT without contrast (CPT® 73700)
  - Suspected component malposition or heterotopic bone – CT without contrast (CPT® 73700)
  - Suspected metal-on-metal implant with high-risk of performance issues from cup-neck impingement and adverse local tissue reaction (ALTR, with Co and Cr ion levels greater than 10 ppb) – US (CPT® 76881 or CPT® 76882) OR MRI without contrast (CPT® 73721)
  - Suspected Aseptic lymphocytic-dominated vasculitis lesion (ALVAL) pseudotumor surrounding metal-on-metal prosthesis – US (CPT® 76881 or CPT® 76882) OR MRI without contrast (CPT® 73721)
  - Suspected tendinitis/bursitis, abductor injury or other soft tissue abnormality – US (CPT® 76881 or CPT® 76882) OR MRI without contrast (CPT® 73721)
    - Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started is required
  - Possible nerve injury – MRI without contrast (CPT® 73721)
- **Knee**:
  - Suspected aseptic loosening or fracture – MRI without contrast (CPT® 73721) OR CT without contrast (CPT® 73700)
  - Suspected infection with negative or inconclusive aspiration culture – US (CPT® 76881 or 76882), MRI without contrast (CPT® 73721), MRI without and with contrast (CPT® 73723) OR CT with contrast (CPT® 73701)
  - Suspected periprosthetic fracture – MRI without contrast (CPT® 73721), OR CT without contrast (CPT® 73700)
  - Suspected osteolysis or component instability, rotation, or wear – MRI without contrast (CPT® 73721), OR CT without contrast (CPT® 73700)
  - Suspected periprosthetic soft tissue abnormality unrelated to infection (e.g. tendinopathy, arthrofibrosis, patellar clunk, impingement of nerves or soft tissue) - US (CPT® 76881 or CPT® 76882), OR MRI without contrast (CPT® 73721)

Proprietary Information of UnitedHealthcare.

General Musculoskeletal Post-Operative Follow-Up (MS-16.2)

MS.PS.0016.2
v2.0.2026

As outlined in General Guidelines (MS-1.0), the following must be met prior to requesting advanced imaging for further investigation and/or treatment planning of general musculoskeletal post-operative (post-op) symptoms (e.g., fracture fixation, tendon/ligament repair, labral repair):

- Plain x-ray imaging of the suspected area must first be obtained after the current post-operative episode of symptoms started and results are available to the provider
- Failure of 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current post-op episode of symptoms started

When all of the above criteria have been met, further investigation in symptomatic individuals is medically necessary for post-operative follow-up as follows:

- **Shoulder**:
  - Post rotator cuff repair – US (CPT® 76881 or CPT® 76882), MRI without contrast (CPT® 73221), MRI with contrast (CPT® 73222) OR CT with contrast if MRI contraindicated (CPT® 73201)
  - Post impingement or labral repair - MRI without contrast (CPT® 73221), MRI with contrast (CPT® 73222) OR CT with contrast if MRI contraindicated (CPT® 73201)
- **Elbow**:
  - Post complex fracture surgery – CT without contrast (CPT® 73200)
  - Post soft-tissue surgery – MRI without contrast (CPT® 73221)
- **Wrist**:
  - Post complex fracture surgery – CT without contrast (CPT® 73200)
  - Post instability and/or ligament surgery (e.g., TFCC, DRUJ instability) surgery – MRI with contrast (CPT® 73222)
- **Hand**:
  - Post soft-tissue or complex fracture surgery – MRI without contrast (CPT® 73218) OR CT without contrast (CPT® 73200)
- **Pelvis**:
  - Post complex pelvic ring/acetabular fracture surgery – CT without contrast (CPT® 72192)
- **Hip**:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Fracture surgery or post-op for avascular necrosis – MRI without contrast (CPT® 73721) or CT without contrast (CPT® 73700)
  - Post Femoroacetabular Impingement or labral repairs – MRI with contrast (CPT® 73722)
- **Knee**:
  - Post fracture or dislocation surgery – CT without contrast (CPT® 73700)
  - Post ligament reconstruction or meniscus tear surgery – MRI without contrast (CPT® 73721) OR MRI with contrast (CPT® 73722)
- **Ankle**:
  - Post complex fracture surgery – CT without contrast (CPT® 73700)
  - Post ligament or tendon injury surgery – US (CPT® 76881 or CPT® 76882) OR MRI without contrast (CPT® 73721)
- **Foot**:
  - Post complex fracture surgery – CT without contrast (CPT® 73700)
  - Post ligament, tendon or plantar plate surgery – US (CPT® 76881 or CPT® 76882) OR MRI without contrast (CPT® 73718)

Evidence Discussion (MS-16)

MS.PS.0016.0
v2.0.2026

The American College of Radiology (ACR) has recommended plain x-rays as the initial study for routine follow up of asymptomatic patients and symptomatic individuals who have undergone surgery for musculoskeletal injury.[1-4] Plain x-rays can identify fractures and show signs of hardware loosening, wear, osteolysis or infection. Blood tests and joint aspiration with synovial fluid laboratory analysis may be sufficient to diagnosis post-surgical infection. Joint aspiration with synovial fluid analysis remains the most useful test for confirming the presence or absence of infection and identifying the causative organism.[2-7] When plain x-rays, and laboratory tests as applicable, are negative or inconclusive and there is a suspicion of post-surgical complications, advanced imaging can help to identify what may be the cause of the individual's symptoms.

When there is suspicion of a post-surgical soft tissue abnormality (e.g., tendinitis, tendinopathy, bursitis, arthrofibrosis), a course of conservative care prior to advanced imaging can allow many individuals to improve[8,9], thus eliminating the need for advanced imaging. This may avoid unnecessary exposure to radiation from imaging and additional costs of imaging. If there is failure to improve, advanced imaging would be appropriate. Suspicion of more significant complications following joint surgery may benefit from advanced imaging without a trial of conservative care.

The ACR further recommended MRI, CT, and US as advanced imaging options when further assessing post-surgical complications. Their recommendations vary based on the clinical scenario.[2-4] Complications with implanted hardware (e.g., loosening, component rotation, hardware fracture) may greatly impair an individual's function and may lead to additional negative sequelae if not addressed in a timely manner. MRI has been identified as accurate diagnostic tools in evaluating aseptic loosening following knee replacement.[10] Suspected torn rotator cuff tendons in individuals that have undergone total shoulder arthroplasty may also be difficult to diagnose without advanced imaging due to the various techniques used to release the subscapularis tendon during surgery.[3] MRI has been demonstrated to have good intra- and inter-rater reliability in determining the structural integrity of tendons following surgery.[11,12] Individuals with metal-on-metal hip replacements are at risk for adverse local tissue reactions including metallosis, pseudotumor and generalized synovitis that could result in tissue damage. Prompt evaluation, including advanced imaging, would be appropriate to best mitigate these risks.[13]

Soft Tissue Mass and Morton's Neuroma (MS-10.1)

MS.ST.0010.1
v2.0.2026

As outlined in General Guidelines (MS-1.0), the following must be met prior to requesting advanced imaging for further investigation and/or treatment planning of soft tissue masses and Morton's neuroma:

- Initial plain x-ray imaging of the suspected area must first be performed after the current episode of symptoms started. Results of these plain x-rays need to be available to the requesting provider
- Additional documentation of clinical features if specifically stated below
- See specific details throughout the section regarding any requirements for when conservative care prior to requesting advanced imaging is required

Soft Tissue Mass

Plain x-ray is indicated as the initial imaging study, with the exception of individuals with cancer predisposition syndrome (If there is a known or suspected soft tissue mass in an individual with a cancer predisposition syndrome, see: Screening Imaging in **Cancer Predisposition Syndromes (PEDONC-2)** in the Pediatric and Special Populations Oncology Imaging Guidelines). History and physical exam of any palpable soft tissue mass should include documentation of any one or more of the following clinical features:

- Increase in volume/size
- More than 5cm in diameter
- Painful
- Deep or subfascial location

After the initial history, exam and plain imaging have been performed and further investigation is needed the following advanced imaging is medically necessary for evaluation of soft tissue masses:

- MRI without and with contrast, or MRI without contrast, or US of the area of interest (CPT® 76881 or 76882) is appropriate when ANY of the following are met after plain x-ray:
  - Soft tissue mass(es) which are increasing in volume/size, more than 5 cm in diameter, painful or deep or in a subfascial location
  - Surgical planning

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- CT with contrast or CT without and with contrast is appropriate when MRI is contraindicated or after a metal limiting MRI evaluation

Advanced imaging is not medically necessary for subcutaneous lipoma with no surgery planned

Tarsal Tunnel Syndrome soft tissue mass entrapment (Baxter's Neuropathy)

After the x-rays have been performed and results are available to the provider, and there has been failure of at least 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started, the following advanced imaging is medically necessary for preoperative planning if mass is suspected as etiology of entrapment:

- US Foot (CPT® 76881 or CPT® 76882) or MRI Foot without contrast (CPT® 73718)

Morton's Neuroma

After the x-rays have been performed and results are available to the provider, and there has been failure of at least 6 weeks of provider-directed conservative treatment, including clinical re-evaluation, occurring after the current episode of symptoms started, the following advanced imaging is medically necessary for further investigation of Morton's Neuroma for preoperative planning:

- US Foot (CPT® 76881 or CPT® 76882), MRI Foot without contrast (CPT® 73718) or MRI Foot without and with contrast (CPT® 73720)

Bone Lesion (MS-10.2)

MS.ST.0010.2
v2.0.2026

As outlined in General Guidelines (MS-1.0), the following must be met prior to requesting advanced imaging for further investigation and/or treatment planning of suspected abnormal bone growth or lesion:

- Initial plain x-ray imaging of the entire bone containing the lesion must first be performed after the current episode of symptoms started. Results need to be available to the requesting provider.

After the x-rays have been performed and further investigation is needed advanced imaging is medically necessary for the following scenarios:

- Diagnosis uncertain based on plain x-ray appearance - MRI without contrast, MRI without and with contrast, or CT without contrast
- Imaging requested for preoperative planning – MRI without contrast, MRI without and with contrast, or CT without contrast
- Plain x-ray reveals an osteochondroma with clinical concern of malignant transformation - MRI without contrast or MRI with and without contrast
- For Paget's Disease - MRI (contrast as requested) can be considered if the diagnosis (based on plain x-rays and laboratory studies) is in doubt or malignant degeneration is suspected
    - Criteria regarding **nuclear medicine imaging** is found in: **Nuclear Medicine (MS-28)**

Cysts (MS-10.3)

MS.ST.0010.3
v2.0.2026

As outlined in General Guidelines (MS-1.0), the following must be met prior to requesting advanced imaging for treatment planning of soft tissue masses and cysts:

- Initial plain x-rays must be performed after the current episode of symptoms started or changed. Results need to be available to the requesting provider.

After the initial imaging has been performed and further investigation is needed for surgical planning to address ganglion or other musculoskeletal related cysts, (e.g., Popliteal) the following advanced imaging is medically necessary:

- **Ganglion Cyst** - US (CPT® 76881 or CPT® 76882), MRI without contrast or MRI without and with contrast
- **Popliteal (Baker's) Cyst** - US (CPT® 76881 or CPT® 76882), MRI Knee without contrast (CPT® 73721)

Advanced imaging is not medically necessary for:

- Ganglia that can be diagnosed by history and physical examination
- Sebaceous cyst, as these cysts are benign and additional imaging typically will not change the treatment plan

Evidence Discussion (MS-10)

MS.ST.0010.0
v2.0.2026

The American College of Radiology (ACR) has recommended the use of x-rays as the initial image when evaluating suspected bone tumor. They recommended that a complete x-ray of the entire lesion-containing bone be evaluated prior to considering any advanced imaging.[1] Many benign bone tumors have a characteristic appearance on plain x-ray. Along with a relevant history and physical examination, x-rays may be sufficient for diagnosis and would avoid additional cost and risks associated with advanced images. If plain x-rays are equivocal, they may still direct further imaging with the correct modality. Furthermore, plain x-ray may provide complementary information to advanced imaging, allowing for a better overall interpretation. Clearly benign findings on exam (lipoma, ganglion, sebaceous cyst) do not need additional imaging prior to treatment unless the imaging was necessary for surgical management or for a possible malignancy.

When diagnostic uncertainty remains and concerns for malignant degeneration still exist, or imaging is requested for surgical planning, advanced imaging would be medically necessary. MRI is a superior modality for evaluation of many bone tumors. The ACR recommended MRI as the primary modality for advanced imaging of primary bone tumors. MRI can be useful in narrowing down differential diagnoses and in determining the need for biopsy.[1] CT may be appropriate when an individual presents with contraindications to MRI.

Current ACR recommendations have supported plain x-ray as an initial imaging option when evaluating individuals with suspicion of superficial soft tissue masses.[2] X-ray can be helpful in visualizing soft tissue masses and aid in further management planning. It is often the modality of choice for initial imaging. US is being recommended as an excellent triage tool more frequently for soft tissue masses that are more superficial, further supporting the recommendation for its use by the ACR.[3,4]US has been found to have high accuracy in defining superficial (superior to investing fascia) soft tissues masses with a sensitivity of 93% and specificity of 98%.[5] A recent study found that US was more predictive of the histology of lipomatous tumors than the use of predictive clinical indicators.[6]

Common clinical features of soft tissue sarcoma can be helpful in the differentiation of soft tissue masses and decisions for additional biopsy. In many cases, a thorough exam, history and initial imaging may be sufficient to determine a diagnosis and management plan.[7] When clinical findings and initial imaging is insufficient to diagnose suspicious soft tissue masses MRI without and with IV contrast is primarily recommended as the next advanced image of choice.[2-4] MRI capabilities present many advantages to other imaging techniques for the use of advanced diagnostics of soft tissue masses. Improved

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

contrast, multiplanar views, visualization of involved vascular structures and better demarcation between tissue types/levels (with the aid of contrast agents) are among the most prominent advantages to MRI.[2,3] When MRI is contraindicated, CT imaging without and with IV contrast can provide similarly diagnostic data as MRI and is considered an important adjunct option to MRI.[2]

ACR imaging recommendations supports both plain xray and ultrasound as initial imaging options when evaluating individuals with suspicion of soft tissue cysts.[2] While x-ray findings may not fully demonstrate a small ganglionic mass they can still be beneficial in visualizing the surrounding anatomy and in determining the next steps for care. In a recent systematic review of 941 ganglion cyst cases MRI and US were the most commonly reported imaging study. It was recommended that US can be a beneficial option for triage. However, it was found that MRI was much better at showing the underlying pathoanatomy of masses and their surrounding area than US when evaluating intraneural ganglion cysts.[8] The utility of MRI for preoperative visibility of dorsal wrist ganglion and any associated pathoanatomy has also been demonstrated. MRI would be more useful for preoperative planning.[9]

General Guidelines (Neck-1.0)

NK.GG.0001.0.A

v1.0.2026

- A pertinent clinical evaluation since the onset or change in symptoms including a detailed history, physical examination, appropriate laboratory studies, and basic imaging such as plain radiography or ultrasound should be performed prior to considering advanced imaging (CT, MR, Nuclear Medicine), unless the individual is undergoing guideline-supported scheduled imaging evaluation. A meaningful technological contact (telehealth visit, telephone call, electronic mail or messaging) since the onset or change in symptoms can serve as a pertinent clinical evaluation.
- Advanced imaging of the neck covers the following areas:
  - Skull base (thus, a separate CPT® code for head imaging in order to visualize the skull base is not medically necessary)
  - Nasopharynx
  - Upper oral cavity to the head of the clavicle
  - Parotid glands and the supraclavicular region
- Ultrasound of neck soft tissues including thyroid, parathyroid, parotid and other salivary glands, lymph nodes, cysts, etc. is coded as CPT® 76536. This can be helpful in more ill-defined masses or fullness and differentiating adenopathy from mass or cyst, to define further advanced imaging.
- CT Neck
  - CT Neck is usually obtained with contrast only (CPT® 70491).
    - With the exception of 4D CT Neck without and with contrast (CPT® 70492) for parathyroid adenoma localization, little significant information is added by performing a CT Neck without and with contrast (CPT® 70492), and there is the risk of added radiation exposure, especially to the thyroid.
    - CT Neck without contrast (CPT® 70490) can be difficult to interpret due to difficulty identifying the blood vessels.
      - Exceptions include:
        - Contrast is generally not medically necessary when evaluating known or suspected tracheal anomalies with CT.
        - Additionally, non-contrast CT is medically necessary for the evaluation of salivary duct stones in the appropriate clinical circumstance where intravenous contrast may obscure high attenuation stones. Dual-phase CT imaging (without and with IV contrast) is not medically necessary in this situation.
    - Contrast enhanced CT is helpful in the assessment of cervical adenopathy and preoperative planning, including in the setting of thyroid carcinomas.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - Contrast may cause intense and prolonged enhancement of the thyroid gland which interferes with radioactive iodine nuclear medicine studies.
  - Use of IV contrast is an important adjunct, however, because it helps to delineate the anatomic relationship between the primary tumor and metastatic disease. Iodine is generally cleared within four to eight weeks in most individuals, so concern about iodine burden from IV contrast causing a clinically significant delay in subsequent whole-body scans (WBSs) or radioactive iodine (RAI) treatment after the imaging followed by surgery is generally unfounded. The benefit gained from improved anatomic imaging generally outweighs any potential risk of a several week delay in RAI imaging or therapy. Where there is concern, a urinary iodine to creatinine ratio can be measured.

- MRI Neck
  - MRI Neck is used less frequently than CT Neck.
  - MRI Neck without and with contrast (CPT® 70543) is medically necessary if CT suggests the need for further imaging or if ultrasound or CT suggests any of the following:
    - Neurogenic tumor (schwannoma, neurofibroma, glomus tumor, etc.)
    - Vascular malformations
    - Deep neck masses
    - Angiofibromas
    - Cystic neck mass
    - Concern for malignancy (see **Squamous Cell Carcinomas of the Head and Neck (ONC-3)**, **Salivary Gland Cancers (ONC-4)**, or **Thyroid Cancer (ONC-6)** as appropriate)
  - MRI Neck without and with contrast (CPT® 70543) is medically necessary if the head and neck surgeon or neurosurgeon, or the provider in consultation with the head and neck surgeon or neurosurgeon, has reasonable clinical concern:
    - for a skull base or nasopharyngeal neoplasm, or potential perineural invasion/ cranial nerve involvement.[2]
    - that extensive dental amalgam may obscure the anatomy on CT in individuals with oral cavity neoplasm.

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence;

Dysphagia and Upper Digestive Tract Disorders (Neck-3.1)

NK.ED.0003.1.A
v1.0.2026

- **General considerations**
  - A detailed history of the dysphagia symptoms is important to distinguish neurogenic, pharyngeal and esophageal disorders.
  - Dysphagia (difficulty swallowing) can be the result of a wide range of benign and malignant processes that affects the body's ability to move food or liquid from the mouth to the pharynx and into the esophagus.
  - A short duration (weeks to months) of rapidly progressive esophageal dysphagia with associated weight loss is highly suggestive of esophageal cancer.
  - Advanced imaging for individuals presenting with isolated globus rarely impacts clinical management. In a study of 148 neck CTs and 104 barium esophagrams done for the evaluation of globus sensation, there were no malignancies detected.
- **Gastroesophageal reflux disease (GERD)**
  - Advanced imaging is not medically necessary for the evaluation of GERD, the diagnosis of which is usually made on the basis of clinical history, in conjunction with endoscopy, pH monitoring, Upper GI Barium Studies, and occasionally manometry. Exceptions would include the following:
    - Non-cardiac chest pain suspected of being GERD should be evaluated first to exclude cardiac and other etiologies. See **Non-Cardiac Chest Pain-Imaging (CH-4.1)** in the Chest Imaging Guidelines.
    - Gastric emptying study (CPT® 78264) for individuals with refractory GERD symptoms, and gastroparesis is being considered.
- **Suspected foreign body impaction and ingested foreign bodies**
  - Plain x-rays are medically necessary as initial imaging.
  - If imaging is inconclusive, and/or there is suspicion of a radiolucent foreign body (such as fish or chicken bones, wood, plastic, thin metal objects, aluminum can pop-ups, etc.):
    - CT Neck and/or Chest with or without contrast (CPT® 70491 or CPT® 70490 or CPT® 71260 or CPT® 71250)
    - If requested, 3-D reconstruction (CPT® 76377 or CPT® 76376) is medically necessary in this setting.
  - The use of oral contrast is discouraged (to avoid the aspiration of contrast material) for acute dysphagia or foreign body impaction, as the contrast may not pass, may be aspirated, and can interfere with subsequent endoscopic intervention.
- **Oropharyngeal dysphagia**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Oropharyngeal dysphagia (difficulty in transferring food from the mouth to the pharynx)
  - Suspected neurologic causes: See appropriate sections in Head Imaging Guidelines.
  - Initial evaluation is with A) a swallow study AND B) direct visualization (with laryngoscopy and/or upper endoscopy).
    - A) Video fluoroscopic swallowing study (VFSS) – (Dynamic radiographic evaluation of swallowing during speech pathologist-guided oral intake of various consistencies). Also referred to as a modified barium swallow study (MBSS).
    - B) Flexible fiberoptic laryngoscopy (FFL), FiberOptic Exam for laryngoscopy (FOE), TransNasal Esophagoscopy (TNE) and/or FEES (Fiberoptic Endoscopic Evaluation of Swallowing). FEES is a dynamic evaluation of swallowing via direct visualization using transnasal laryngoscopy during speech pathologist-guided oral intake of various consistencies.
    - CT Neck with contrast (CPT® 70491) is medically necessary for any documented anatomic abnormalities suggested by direct visualization—i.e., on exam with flexible laryngoscopy or rigid video stroboscopy or FEES.
      - Completion of a radiographic swallow study, though potentially helpful, is NOT medically necessary prior to the requested advanced imaging in such a case.

- **Esophageal dysphagia**
  - Esophageal dysphagia (difficulty in transferring food down the esophagus in the retrosternal region, e.g., food sticking in the neck or chest)
    - Initial evaluation is with barium esophagram or upper gastrointestinal endoscopy.
    - If requested, esophageal manometry is medically necessary
    - Advanced imaging is medically necessary for the evaluation of structural abnormalities demonstrated on either esophagram or direct visualization (i.e., laryngoscopy/upper GI endoscopy), such as an external compression, tumor, stricture, diverticulum, etc.
      - Contrasted CT Neck (CPT® 70491), CT Chest (CPT® 71260), **and/or** CT Abdomen (CPT® 74160) depending on the location of the abnormality identified.
- **Suspected perforation, abscess, or fistula**
  - CT Neck, Chest, **and/or** Abdomen, contrast is medically necessary (preferably with contrast- CPT® 70491, CPT® 71260, CPT® 74160), depending on location.
- **Hiatal hernia**
  - See **Hiatal Hernia (AB-12.3)** in the Abdomen Imaging Guidelines.
- **Globus sensation**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Globus sensation is a feeling of a lump or foreign body in the throat. In general, laryngoscopy, endoscopy, and physical examination will rule out malignant causes and advanced imaging is not medically necessary for evaluation. It is considered a mild form of dysphagia.
  - Direct visualization with laryngoscopy and/or upper endoscopy should be performed prior to advanced imaging.
    - Unremarkable laryngoscopy and/or upper endoscopy does not preclude advanced imaging if **red flag** symptoms are also present:
      - weight loss
      - odynophagia/throat pain
      - referred otalgia
      - hoarseness
      - hemoptysis, **AND/OR**
      - other unilateral presentation of concerning symptoms.
    - CT Neck with contrast (CPT® 70491) for ANY of the following:
      - Negative or equivocal findings on laryngoscopy and/or upper endoscopy with any **red flag** present
      - Known history of upper aerodigestive or esophageal malignancy
      - Known history of lymphoma
      - History of previous neck, esophageal, or gastric surgery–see below, and see **Background and Supporting Information** for post-operative oropharyngeal dysphagia associated with Anterior Cervical Spine Surgery (ACSS).
      - Palpable abnormality on physical examination such as neck mass

- **Post-operative dysphagia**
  - Dysphagia following surgery on the oropharynx, soft tissues of the neck, cervical spine, esophagus, or stomach:
    - In the immediate post-operative period, within 3 months of the surgery, the concern is for fluid collections, anastomotic leaks, perforations, and abscess. Prior laryngoscopy/upper endoscopy and barium esophagram are not medically necessary initially.
      - CT Neck with contrast (CPT® 70491) **AND/OR** CT Chest with contrast (CPT® 71260)
    - In the delayed post-operative period—three months or greater from surgery, the primary modalities for evaluation are history, physical, endoscopy (laryngoscopy or EGD) and/or barium esophagram/videofluoroscopic swallow study (VFSS) to direct any additional advanced imaging. See also **Background and Supporting Information**.
      - If the results of endoscopy and/or barium esophagram or VFSS are abnormal or inconclusive, the following is medically necessary:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

    - CT Neck with contrast (CPT® 70491) **AND/OR** CT Chest with contrast (CPT® 71260)
- **Suspected vascular ring** (See **Dysphagia (PEDNECK-5)**)
    - Advanced imaging can be performed if a vascular ring is suspected by, or in consultation with, the treating specialty, i.e., cardiothoracic surgery, cardiology, otolaryngology, and/or pulmonology. More commonly, this congenital pathology would be suspected in a much younger population; however, dysphagia lusoria is a relatively rare condition involving a vascular ring (usually an aberrant right subclavian artery). As children, these individuals are asymptomatic but develop worsening dysphagia later in adulthood, presumably secondary to increasing calcification and blood pressure.
        - CTA Chest (CPT® 71275) **OR** MRA Chest (CPT® 71555) are the preferred imaging studies in the evaluation of a suspected vascular ring.
        - CT Chest with contrast (CPT® 71260) **OR** MRI Chest without contrast (CPT® 71550) **OR** MRI Chest without and with contrast (CPT® 71552) can be performed as alternative exams in the evaluation of suspected vascular ring.

Background and Supporting Information

- Postoperative oropharyngeal dysphagia is one of the most common complications following anterior cervical spine surgery (ACSS), and is considered by some to be an inevitable result of this surgery, rather than a surgical complication.
- Severe dysphagia after ACSS should prompt immediate evaluation to exclude any potentially reversible surgical complication such as bone graft dislodgement, hematoma or retropharyngeal abscess.
- In general, history, exam, plain films, laryngoscopy, and videofluoroscopic swallow studies are considered the primary modalities for evaluation. The videofluoroscopic swallow study, in fact, is the gold standard in evaluation, and is very sensitive in individuals post-ACSS, and should be considered the initial evaluation in individuals who are status post ACSS with globus sensation, or mild dysphagia.

Evidence Discussion

Dysphagia

- Imaging studies are complementary to endoscopy (and in certain cases, also manometry) in the evaluation of dysphagia. The optimal imaging study depends on the nature and location of the dysphagia, as well as clinical setting. Fluoroscopy, however, is usually the first line choice.[4]
- Modified barium swallow study (videofluoroscopic procedure performed in conjunction with a speech therapist) is generally first line for oropharyngeal dysphagia. CT is generally not medically necessary because it does not assess motility, nor the oropharyngeal and esophageal mucosa as well. CT may be helpful for subsequent

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

evaluation if initial studies are not revealing, or if there are suspicious findings on direct visualization.[10]

- Barium esophagram is medically necessary for initial imaging of retrosternal dysphagia. CT is generally not medically necessary because it does not assess motility, nor esophageal mucosa as well. CT may be helpful if subsequent evaluation if initial studies are not revealing, or if there are suspicious findings on direct visualization and/or barium esophagram.[10]
- Fluoroscopy still remains the imaging of choice for initial evaluation of early (as well as late) post-operative dysphagia, within the oropharyngeal or retrosternal regions. Utilizing a water-soluble contrast first, followed by barium if necessary, suspected leaks or fistulas may be investigated. Esophagrams are highly specific for leaks, but not as sensitive as CT. If high clinical suspicion remains following negative esophagram, esophagography and CT combined have a sensitivity and negative predictive value of 100%, but a specificity of 27% and positive predictive value of 56%.[10]
- For oropharyngeal and retrosternal dysphagia, contrasted CT of the neck and/or chest is medically necessary when there is concern of early post-operative complications, such as leak, fluid collection, abscess, or hematoma.[10]

Dysphagia and Upper Digestive Tract Disorders Health Equity Considerations

- Dysphagia is more common in individuals who are female, White/Caucasian, non-Hispanic, of older age, low income, of public insurance, and unemployed.
- Individuals who are female and White/Caucasian are less likely to pursue diagnostic testing for upper digestive tract disorders.
- GERD is more common in females, but the rate of complications is higher in males.
- Hispanic and Latino Americans have the highest prevalence of GERD among all minority populations.
- Reflux is more common in individuals who are female, White/Caucasian, non-Hispanic, and of public insurance.

Neck Mass/Swelling/Adenopathy (Neck-5.1)

NK.NM.0005.1.A

v1.0.2026

- Cervical lymphadenitis is common and follows most viral or bacterial infections of the ears, nose and throat. Painful acute lymphadenopathy should be treated with a trial of conservative therapy for 2-weeks, including antibiotics if appropriate. If there is improvement with conservative treatment, advanced imaging is not medically necessary. If the adenopathy persists, it can be imaged as per below**.**
- Ultrasound (CPT® 76536) is medically necessary for **ANY** of the following:
  - Cervical adenopathy/lymphadenitis or an inflammatory, infective, or reactive mass that has failed a 2-week trial of treatment (including antibiotics if appropriate) or observation
  - Anterior neck masses
  - Posterior neck masses
  - Any ill-defined mass, fullness or asymmetry
- CT Neck with contrast (CPT® 70491) is medically necessary if:
  - Neck mass with any ONE of the following:
    - Size ≥1.5cm
    - Mass present ≥2 weeks or of uncertain duration
    - Non-tender neck masses
    - Firm texture or fixation of the mass
    - Suspected peritonsillar, retropharyngeal or other cervical space abscess
    - Ulceration of skin overlying the neck mass
    - Ear pain ipsilateral to the neck mass
    - Associated onset of hoarseness persistent for greater than 3-weeks
    - Associated onset of throat pain, tonsil asymmetry, oral or oropharyngeal ulceration, weight loss, or hemoptysis
    - History of malignancy that would be primary or metastatic to the neck
    - Prior ultrasound results, if performed, are suspicious or indeterminate for malignancy
  - Isolated tonsil asymmetry with concerning features such as suspicious appearance, firmness, palatal immobility, rapid unilateral enlargement, history of malignancy, or immune compromise.
  - Carcinoma found in a lymph node or other neck mass
  - Suspected or known sarcoidosis
  - Preoperative evaluation of any neck mass

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - Foreign body migration with neck swelling
- MRI Orbit/Face/Neck without and with contrast (CPT® 70543) is medically necessary if:
  - CT suggests the need for further imaging
  - Ultrasound or CT suggests neurogenic tumor (schwannoma, neurofibroma, glomus tumor, etc.), vascular malformations, cystic neck mass, deep neck masses, or angiofibroma.
- MRI Orbit/Face/Neck without and with contrast (CPT® 70543) is also medically necessary without prior CT Neck or ultrasound requirement, if the head and neck specialist, or the provider in consultation with the head and neck specialist, has reasonable clinical concern for:
  - skull base or nasopharyngeal neoplasm, **OR**
  - potential perineural invasion/cranial nerve involvement, **AND/OR**
  - extensive dental amalgam which may obscure the anatomy on CT in individuals with oral cavity neoplasm.
- Congenital cervical sinus, fistula, or cyst for preoperative planning:
  - MRI Orbit/Face/Neck without and with contrast (CPT® 70543) **OR**
  - CT Neck with contrast (CPT® 70491)
    - For fourth branchial cleft cyst/sinus/fistula, barium swallow is medically necessary in addition to the above conventional imaging.

Background and Supporting Information

- Inflammatory neck adenopathy is often associated with upper respiratory infection, pharyngitis, dental infection, HIV and toxoplasmosis. Occasionally it is associated with sarcoidosis and tuberculosis.
- Malignancy is a greater possibility in adults that are heavy drinkers and smokers, but HPV associated disease is on the rise and there can be a high suspicion for malignancy even without these traditional risk factors.
- ENT evaluation can be helpful in determining the need for advanced imaging.
- Although CT and MRI can have characteristic appearances for certain entities, biopsy and histological diagnosis are the only way to obtain a definitive diagnosis. The preferred initial method of biopsy is Ultrasound guided core needle biopsy of the mass.
- The most common causes of neoplastic cervical adenopathy are metastasis from head and neck tumors or lymphoma.
- Tonsil asymmetry is a common exam finding in both adults and children and is often benign. In cases of associated suspicious characteristics, neck imaging is medically necessary, even if there is not an associated neck mass.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- MRI has great specificity for determining the boundaries and prevalence of developmental neck cysts. It may thus be considered optimal to use only MRI, which leads to a correct diagnosis in more than 90% of cases.
- For the evaluation of neck masses by CT or MRI, the diagnostic accuracy is 96%, the sensitivity is 96.30%, and the specificity is 95.65%.

Evidence Discussion

- CT has several benefits that support its utilization as a primary imaging modality, including its availability and cost. CT imaging is generally easily tolerated by individuals because of short scanning time (<5 minutes) and large scanner bore. While CT utilizes ionizing radiation, the average dose of 3 mSv (equivalent to approximately 150 chest x-rays) is considered acceptable in the adult population.[17]
- MRI is preferred for tumors of the nasopharynx or when there is a cranial nerve concern on physical examination because of its sensitivity to abnormalities of the skull base and in the detection of perineural spread. MRI also offers improved tissue contrast and can help detect subclinical tumors not evident with nasal endoscopy.[17]
- Ultrasound is also used to characterize neck masses, to guide tissue sampling, and to search for additional masses. It is both noninvasive and inexpensive. Ultrasound is, however, best suited for evaluation of superficial tissue, in situations where there will be a delay in obtaining CT or MRI, if the use of contrast medium is contraindicated, or as an adjunct to expedite FNA biopsy.[11]

Recurrent Laryngeal Nerve Palsy (Neck-7.1)

NK.PA.0007.1.A
v1.0.2026

- The following are medically necessary with new diagnosis of idiopathic unilateral vocal fold paralysis/immobility or weakness, as identified on videostroboscopy or laryngoscopy by an Otolaryngologist—Head and Neck surgeon, or a clinician in consultation with such a specialist:
  - MRI Brain without and with contrast (CPT® 70553) **OR** MRI Brain without contrast (CPT® 70551)

    AND
  - MRI Orbit/Face/Neck with and without contrast (CPT® 70543) **OR** CT Neck with contrast (CPT® 70491)

    AND
  - CT Chest with contrast (CPT® 71260) is medically necessary for left vocal fold paralysis and may be medically necessary for right vocal fold paralysis. If requested, see **Background and Supporting Information**.

Background and Supporting Information

- The right and left recurrent laryngeal nerves supply the motor innervation of the right and left vocal folds/cords, respectively. They are branches off of the Vagus Nerve, CN X. The entire pathway from origin to endpoint of this nerve must be visualized in cases of presumed idiopathic vocal fold paralysis, newly identified by laryngoscopy, to search for a possible cause. From the origin of the vagus at the medulla oblongata to the looping down into the superior mediastinum and back to the neck of its branching nerve (the recurrent laryngeal nerve)—advanced imaging is medically necessary to screen for a cause for otherwise idiopathic vocal fold paralysis/paresis. The greater the degree of motion impairment, the more likely it is to find a cause on imaging.
- The superior mediastinum is most noteworthy for containing the take-off point of the three great branches of the aortic arch: the brachiocephalic trunk (also known as the innominate artery), the left common carotid artery, and the left subclavian artery.
- The extent of the CT Neck with contrast, to be inclusive of the entirety of the course of the recurrent laryngeal nerve in question, would have to extend to the "thoracic inlet" portion of the superior mediastinum on the right, and the "aortic triangle" portion of the superior mediastinum on the left.
- Contrasted CT Chest is medically necessary with left vocal cord palsy due to the lower course of the recurrent laryngeal nerve branch on the left side of the body. It curves inferior to the aortic arch and ascends in the groove between the trachea and

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

the esophagus. However, the course of the recurrent laryngeal nerve on the right side may be as low as the level at which the brachiocephalic artery meets the subclavian artery, and this area of the thoracic inlet may or may not be contained within the anatomic extent of a CT neck at all institutions.

Evidence Discussion

Evaluation of Idiopathic Unilateral Vocal Fold Paralysis/Immobility

- Idiopathic unilateral vocal fold immobility is a diagnosis of exclusion. When it is noted that a vocal cord is immobile on laryngoscopy, the etiology must be sought. If it is not apparent on history and laryngoscopy, this work-up involves imaging the entire pathway of the motor nerve supply to the involved side of the larynx—from the brain to the superior mediastinum.[1]
- Repeat imaging for a pre-existing diagnosis of idiopathic unilateral vocal cord paralysis may be considered on a case by case basis. Recommendations include possibly repeating advanced imaging as above within 5 years after initial diagnosis and workup, or performing regular (annual) clinical evaluations with imaging reserved for the development of new symptoms or exam findings.[5]

Recurrent Laryngeal Nerve Palsy Health Equity Considerations

- Individuals with a higher socioeconomic status typically receive a greater number of interventions for recurrent laryngeal nerve palsy, as well as a longer duration of care.

Thyroid Nodule (Neck-8.1)

NK.PT.0008.1.A
v1.0.2026

- **Serum thyrotropin (TSH)** should be measured in the initial evaluation of thyroid nodule/mass/asymmetry/goiter but is not medically necessary for follow-up imaging.
- **Ultrasound (US) Neck (CPT® 76536)** is medically necessary prior to advanced imaging for a palpable thyroid nodule/mass/asymmetry/goiter, including such examples as:
  - Nodules incidentally found on CT, MRI, or PET (focal activity)
  - Palpable solitary nodule
  - Palpable multinodular goiter
  - Suspicion of a nodule in an individual with a difficult neck examination
  - Prior history of neck radiation
  - Family history of medullary carcinoma, multiple endocrine neoplasia (MEN-2), or papillary thyroid carcinoma
  - Unexplained cervical lymphadenopathy
  - Preoperative thyroidectomy
- See **Thyroid Cancer-Surveillance/Follow-Up (ONC-6.4)** for thyroid nodules that are biopsy proven thyroid cancer but are being monitored on active surveillance.
- A thyroid nodule detected for the first time during pregnancy should be managed in the same way as in non-pregnant individuals, except for avoiding the use of radioactive agents for diagnostic and therapeutic purposes.
- **Nuclear scan (CPT®78013 or CPT® 78014)** is medically necessary if the serum TSH is subnormal and ANY of the following:
  - Single or multiple thyroid nodules
  - Suspicion of ectopic thyroid tissue
  - Presence of thyroid nodule in the setting of Grave's disease
- **Nuclear medicine thyroid scan (CPT® 78013 or CPT® 78014)** is medically necessary for ANY of the following (TSH is not medically necessary prior to imaging in the below settings):
  - Evaluate eligibility for radioiodine therapy
  - Select nodules to biopsy in multinodular goiter even if TSH not low
  - Substernal goiter with compressive symptoms (e.g., dyspnea, stridor, cough, dysphonia, dysphagia)
  - Non-diagnostic or indeterminate FNA of thyroid nodule (e.g., follicular lesion of undetermined significance), to see if hot (functioning) nodule that may be benign vs cold nodule

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- **CT Neck with contrast (CPT® 70491), or CT Neck without contrast (CPT® 70490), or MRI Orbit/Face/Neck without contrast (CPT® 70540), or MRI Orbit/Face/Neck without and with contrast (CPT® 70543):**

  Imaging should be done only after initial thyroid ultrasound has been performed.

  MRI and CT are not medically necessary for routine thyroid nodule evaluation and should only be considered after US for:
  - evaluation of extent of known substernal goiter.
  - suspected airway compression (i.e., subjective sense of dyspnea or choking sensation in the clinical history with known multinodular goiter).
  - presence of pathologic lymph nodes in cervical regions not visualized on ultrasound.
  - clinically suspected advanced thyroid disease, including invasive primary tumor.
  - any preoperative planning for thyroid disease.
- **CT Chest without contrast (CPT® 71250) or with contrast (CPT® 71260)** is also medically necessary for:
  - preoperative planning for individuals with substernal extension of the thyroid, pulmonary symptoms, or abnormalities on chest x-ray, and should be ordered by a surgeon or in consultation with a surgeon.
- **Thyroglossal duct cysts (TGDC)** are the most common type of congenital neck cyst of the midline neck, and may be first diagnosed in adulthood, though more commonly in early childhood.
  - A physical exam feature includes the rise and fall of the midline mass with protrusion and retraction of the tongue, due to its embryonal connection to the foramen cecum.
  - There is a small risk (about 1%) of incidental malignant degeneration within the TGDC, particularly within adults, and therefore, it is uniformly managed surgically. The Sistrunk procedure, which involves resection of the TGDC and its complete tract within the surrounding midline tissues—to include the middle third of the hyoid bone, is considered the gold standard in surgical management with a less than 5% risk of recurrence.
  - Advanced imaging, per surgeon's request—or a provider in consultation with the head and neck surgeon, to include Neck Ultrasound (CPT® 76536) **AND/OR** CT Neck with contrast (CPT® 70491) or MRI Neck with and without contrast (CPT® 70543), is medically necessary pre-operatively, or for the evaluation of a suspected recurrence.

Background and Supporting Information

- The American College of Radiology (ACR) Thyroid Imaging, Reporting, and Data System (TI-RADS), consisting of five levels, is utilized for recommendations in

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

determining US follow-up vs FNA of thyroid nodule(s). TI-RADS levels are determined based on the ultrasound appearance of the nodule.

- The American Thyroid Association (ATA) guidelines from 2015 also use imaging characteristics and size for thyroid nodule risk stratification; however, size cutoffs are slightly more generous when compared to ACR-TIRADs. Sonographic imaging and/or biopsy requests in accordance with ATA criteria are appropriate.
- Fine-Needle Aspiration (FNA) biopsy is medically necessary for suspicious and/or large thyroid nodules prior to CT or MRI imaging.
- Ultrasound is not used to screen: 1) the general population, 2) individuals with normal thyroid on palpation with a low risk of thyroid cancer, 3) individuals with hyperthyroidism, 4) individuals with hypothyroidism or 5) individuals with thyroiditis. Conversely, US is medically necessary in individuals who have no symptoms but are high-risk as a result of: history of head and neck irradiation, total body irradiation for bone marrow transplant, exposure to fallout from radiation during childhood or adolescence, as well as family history of thyroid cancer syndromes such as MEN-2, medullary or papillary thyroid cancer, Cowden's disease, familial adenomatous polyposis, Carney complex, and Werner syndrome/progeria.
- There is insufficient evidence supporting the use of PET to distinguish indeterminate thyroid nodules that are benign from those that are malignant.
- 18FDG-PET imaging is not medically necessary for the evaluation of thyroid nodules with indeterminate cytology. Routine preoperative 18FDG-PET scanning is not medically necessary.
- Elastography provides information about nodule stiffness that is complementary to gray scale ultrasound findings in nodules with indeterminate cytology or ultrasound findings. It should not be used as a substitute for gray scale ultrasound.
- Use of ultrasound contrast medium is not medically necessary for the diagnostic evaluation of thyroid nodules and its current use is restricted to definition of size and limits of necrotic zones after minimally invasive nodule ablation techniques.
- For prior history of neck radiation and family history of medullary carcinoma, MEN-2, or papillary thyroid carcinoma, US Neck can be ordered as a baseline test. With an indeterminate or abnormal initial US, follow-up studies should be directed by the relevant Neck or Oncology guideline criteria.

Evidence Discussion

- Ultrasound (US) plays a key role in determining which nodules display characteristics suspicious for malignancy and warrant biopsy. Of palpable thyroid nodules, the American College of Radiology (ACR) states, "US provides high-resolution imaging to show that the palpable abnormality is within the thyroid and is the best study to characterize the nodule for the risk of malignancy".[5] US is also the best study to demonstrate goiter size and evaluate thyroid morphology.[5] US has a sensitivity of 88%, a specificity of 86%, and a diagnostic accuracy of 92%.[14]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Nuclear imaging with a radionuclide uptake and scan also plays an important role in thyroid imaging. In the setting of a suppressed thyroid stimulating hormone (TSH) level, nuclear imaging helps to determine whether the individual has thyrotoxicosis.[5]
- A thyroid nuclear scan, in conjunction with thyroid ultrasound, is also useful in the setting of a multinodular goiter and a normal TSH to identify hypofunctioning or isofunctioning nodules which should be targeted for biopsy.[5]
- Neck CT is useful in determining the extent of a substernal goiter, evaluating whether a goiter is causing tracheal compression or deviation, assessing the extent of invasive thyroid cancer, or for preoperative imaging. It does not have a role in distinguishing benign from malignant thyroid nodules.[5]
- Neck CT is preferred to neck MRI, as there is less respiratory motion artifact.[5]
- FDG-PET/CT does not have a role in the initial imaging of a thyroid nodule.[5]

Hyperthyroidism and Hypothyroidism (Neck-8.2)

NK.PT.0008.2.A
v1.0.2026

- Hyperthyroidism suspected
  - Thyroid Uptake Study (CPT® 78012 or CPT® 78014) if ONE of the following:
    - TSH below normal range and elevated free T4 and/or free T3, OR
    - Subclinical hyperthyroidism with TSH <0.1 mU/L and normal free T4 and free T3, OR
    - Subclinical hyperthyroidism with TSH below the lower limit of normal but ≥0.1 and normal free T4 and free T3 in the setting of any of the following:
      - Age ≥65
      - Symptoms of hyperthyroidism
      - Presence of cardiac disease or osteoporosis
  - Ultrasound (US) Neck (CPT® 76536) if any of the following:
    - Palpable nodule on examination
    - Nuclear scanning is suggestive of thyroid nodular disease
    - Diagnostic uncertainty regarding the etiology of hyperthyroidism based on clinical presentation and initial biochemical evaluation
    - To evaluate thyroid dimensions for planning RAI treatment
    - Nuclear scanning is contraindicated (i.e., pregnancy, breastfeeding etc)
- Hyperthyroidism on therapy---For individuals with thyroid hormone levels (TSH, free T4 and free T3) within the normal, hypothyroid, or hyperthyroid range while receiving treatment with an anti-thyroid medication (methimazole or propylthiouracil/PTU):
  - Nuclear Scan (CPT® 78013 or CPT® 78014) if ONE of the following:
    - To determine the cause of hyperthyroidism if there was no diagnostic scan prior to the start of medical therapy
    - To characterize the uptake in a thyroid nodule(s) to properly triage the nodule for FNA if there was no diagnostic scan prior to the start of medical therapy
  - Thyroid Uptake Study (CPT® 78012 or CPT® 78014) if:
    - plan is for radioactive iodine therapy as definitive hyperthyroidism treatment.
- Hypothyroidism: There is no role for thyroid imaging in the workup of hypothyroidism in adults. Imaging for thyroid morphology does not help differentiate among causes of hypothyroidism, and all causes of hypothyroidism will have decreased radioiodine uptake.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Evidence Discussion

- The etiology of thyrotoxicosis is not always apparent in clinical presentation and therefore the use of diagnostic imaging studies is medically necessary to determine the etiology of hyperthyroidism.
- Thyroid nuclear scans play a central role in thyroid disease evaluation. They provide a planar image of the thyroid gland using a gamma camera to assess potential variability in the concentration of the radioisotope within thyroid tissue and can be combined with measurements of uptake of specific tracers and provide very useful information regarding thyroid pathology and function.[5]
- Imaging with a radioiodine uptake and scan provides a valuable benefit as it can help confirm the cause for thyrotoxicosis and helps to decide the most appropriate treatment, which may vary depending on cause of hyperthyroidism.[5]
- Imaging with a thyroid nuclear scan also has a role in planning therapy with radioactive iodine.
- Radioiodine uptake and scans can distinguish between high-uptake causes of thyrotoxicosis, such as Graves disease, toxic adenoma, and toxic multinodular goiter, and low-uptake causes, such as subacute thyroiditis.[5]
- The scan component is helpful in differentiating between the high-uptake causes that show a focal uptake pattern, such as toxic adenoma or toxic multinodular goiter, and the high uptake causes that show a diffuse uptake pattern such as Graves disease.[5]
- If radioiodine therapy is planned, the uptake component of the scan can then help determine the dose.[5]
- A neck ultrasound is the best imaging study to evaluate thyroid morphology and can be a helpful adjunct study to a radioiodine uptake. Although a Doppler ultrasound may help to distinguish the cause of hyperthyroidism, a radionuclide uptake study is still preferred because it directly measures thyroid activity rather than inferring it based on blood flow.[5]
- When a radioactive uptake scan shows nodules from toxic multinodular goiter or toxic adenoma, a neck ultrasound can confirm presence of nodules and also evaluate for suspicious features of malignancy.[5]
- Though radioactivity exposure exists with the use of radioactive scans, the studies are an invaluable resource when helping to establish the cause of hyperthyroidism and guide treatment; guidelines as to when it is appropriate to order should be followed to avoid unnecessary radiation exposure.[5]
- There is no role for imaging in the workup of hypothyroidism in adults. Imaging for thyroid morphology does not help differentiate among causes of hypothyroidism, and all causes of hypothyroidism will have decreased radioiodine uptake.[5]

Thyroid Health Equity Considerations

- Racial and ethnic minorities with thyroid disease have worse health outcomes for both benign and malignant disease.
- Socioeconomic status, insurance status, and differential access to healthcare all contribute to disparities in health outcomes.

Parathyroid Imaging (Neck-8.3)

NK.PT.0008.3.A
v1.0.2026

- Classic primary hyperparathyroidism
  - Parathyroid Planar Imaging (CPT® 78070), Parathyroid Planar Imaging with SPECT (CPT® 78071), or Parathyroid Planar Imaging with SPECT/CT (preferred study) (CPT® 78072) AND/OR Ultrasound (CPT® 76536) AND/OR 4D CT Neck without and with contrast (CPT® 70492) are medically necessary if BOTH of the following conditions are met:
    - PTH and Calcium levels are elevated (See **Background and Supporting Information**)
    - Intention of the study is preoperative localization
      - All parathyroid nuclear scan codes (CPT® 78070, CPT® 78071, CPT® 78072) include thyroid subtraction when performed and no additional thyroid nuclear scan CPT codes are required unless otherwise indicated in **Thyroid Nodule (Neck-8.1)** or **Hyperthyroidism and Hypothyroidism (Neck 8.2)**.
      - Reporting or billing CPT® 78800 for the purpose of intraoperative parathyroid localization using a gamma probe is not medically necessary if performed along with a parathyroid nuclear scan (CPT® 78070, CPT® 78071, CPT® 78072).
      - Ultrasound (CPT® 76536) can be ordered independently to evaluate the thyroid per criteria in **Thyroid Nodule (Neck-8.1)** or **Hyperthyroidism and Hypothyroidism (Neck 8.2)**.
      - 3D Imaging (CPT® 76376 or CPT® 76377) is medically necessary with a 4D CT Neck.
  - MRI Neck without and with contrast (CPT® 70543) for cases of re-operation, difficult localization or ionizing radiation contraindication as ordered by an Endocrinologist, Parathyroid surgeon, or Radiologist or any provider in consultation with one of these specialists.
  - CT Chest with contrast (CPT® 71260) in rare circumstances in the evaluation of ectopic mediastinal parathyroid adenomas as ordered by an Endocrinologist, Parathyroid surgeon, or Radiologist or any provider in consultation with one of these specialists.
  - Choline PET/CT (CPT® 78815 or CPT® 78816) is considered experimental and investigational for preoperative localization in cases of primary hyperparathyroidism.
  - Repeat imaging is medically necessary both in individuals with prior non-localizing imaging who have not yet undergone parathyroid exploration OR in cases of hyperparathyroidism that recurs or persists after parathyroid surgery if reimaging is

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

being ordered by a surgeon or any provider after consultation with a surgeon with expertise in parathyroidectomy.

- Primary hyperparathyroidism variants
  - Primary hyperparathyroidism with non-elevated serum calcium (serum calcium level normal and PTH elevated)
    - Confirmatory study is elevated ionized calcium, elevated albumin corrected calcium or elevated historic calcium levels.
  - Hypercalcemia with inappropriately non-suppressed PTH (calcium level elevated and PTH normal)
    - PTH level ≥25 pg/mL is consistent with primary hyperparathyroidism.
    - See **Background and Supporting Information** for more information.
  - Intention of parathyroid imaging should be for pre-operative localization.
  - Use the same guidance on imaging modalities as described in "classic" primary hyperparathyroidism.

Primary Hyperparathyroidism variants:

	Calcium	PTH	Confirms/strongly suggests primary hyperparathyroidism
Classic primary hyperparathyroidism	High	High	Yes
Primary hyperparathyroidism with non-elevated serum calcium	Normal	High	Elevated ionized albumin corrected or historic calcium levels*
Hypercalcemia with inappropriately non-suppressed PTH	High	Normal	PTH ≥25 pg/ml

- Normocalcemic hyperparathyroidism
  - Serum calcium levels (including ionized calcium levels) are always normal and PTH levels are elevated.
  - Secondary causes of PTH elevation are excluded. See **Background and Supporting Information** for differential diagnosis of secondary hyperparathyroidism.
  - Calcium, PTH and clinical status should be monitored annually.
    - In the event of laboratory progression to hypercalcemia, refer to "classic" primary hyperparathyroidism for imaging guidance.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

    - In the event of clinical progression (decline in bone mineral density or new fracture/renal stone/nephrocalcinosis), imaging for the intent of preoperative localization is as requested by or after consultation with a specialist or any provider in consultation with a specialist.
- Secondary renal hyperparathyroidism
  - Serum calcium levels are low or normal (but may also be elevated in more advanced disease) and PTH levels are very elevated.
  - Imaging for the intent of preoperative localization as requested by or after consultation with a specialist if all of the following are met:
    - Individual has stage 3a-stage 5 chronic kidney disease (GFR<60).
    - PTH level is >9x upper limit of normal reference range for the lab testing facility (~585 pg/mL) despite standard medical or pharmacologic therapy (calcimimetics, calcitriol and/or vitamin D analogs).
- Tertiary hyperparathyroidism
  - Serum calcium and PTH levels are elevated as a result of long standing secondary hyperparathyroidism in individuals on renal replacement therapy or after renal transplant.
  - Imaging for the intent of preoperative localization as requested by or in consultation with a specialist.

Hyperparathyroidism subtypes:

	Calcium	PTH	Clinical Hallmarks
Normocalcemic Hyperparathyroidism	Normal	High	Calcium never elevated
Secondary Renal Hyperparathyroidism	Low/Normal/High	Very High	Stage 3a-5 CKD, PTH >9x ULN
Tertiary Hyperparathyroidism	High	High	ESRD/renal transplant

Background and Supporting Information

- Hypercalcemia in individuals with primary hyperparathyroidism may be determined by elevated serum calcium, elevated serum ionized calcium, elevated serum calcium level corrected for albumin, or historic calcium elevation. A comparison of serial measurements of calcium is helpful in determining the presence of true hypercalcemia as calcium levels may be variable over time.
- Parathyroidectomy candidacy should be determined by the provider; however, national guidelines recognize the following criteria for surgery:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - All individuals <50 years of age, regardless of whether objective features are present or absent
  - All symptomatic individuals, including those with kidney stones, hypercalcemic crises, pathologic fractures or other associated symptoms
  - Individuals with findings concerning for parathyroid cancer (very high calcium >13)
  - All asymptomatic individuals with the following:
    - Serum calcium >1.0 mg/dl (0.25 mmol/l) above the normal range
    - BMD by DEXA: T-score ≤2.5 at the lumbar spine, total hip femoral neck or distal 1/3 radius (The forearm- i.e., distal 1/3 radius is preferentially impacted by primary hyperparathyroidism as this area is rich in cortical bone.)
    - Vertebral fracture by x-ray, CT, MRI and vertebral fracture assessment
    - Estimated glomerular filtration rate of less than 60 ml/min
    - Urinary calcium excretion >400 mg in 24 hours
    - Nephrolithiasis or nephrocalcinosis by x-ray, ultrasound or CT
  - Asymptomatic individuals who cannot participate in appropriate medical surveillance
  - Asymptomatic individuals desiring definitive surgical management
- For cases of “normocalcemic hyperparathyroidism” in which primary hyperparathyroidism is not confirmed, additional investigation for secondary causes of hyperparathyroidism (renal insufficiency, hypercalciuria as a primary renal abnormality, vitamin D deficiency and gastrointestinal malabsorption problems such as short gut syndrome, celiac disease, Crohn's disease or a prior Roux-en-Y bypass surgery) is medically necessary.
- For cases of hypercalcemia in which primary hyperparathyroidism is not confirmed, additional consideration for other causes of hypercalcemia (malignancy including PTH-RP mediated and myeloma, granulomatous disease, FHH, medications including thiazide diuretics, excessive calcium/vitamin D supplementation and the history of or present lithium use) is medically necessary.

Evidence Discussion

- The purpose of parathyroid imaging is to aid in localizing hyperfunctioning parathyroid gland(s) for the purpose of curative surgery. Imaging has no role in the diagnosis of hyperparathyroidism.[1]
- There may be a need for more than one modality in the localization of a parathyroid adenoma as studies have shown no one modality is superior over others.[1]
- The sensitivity and positive predictive value of imaging modalities will vary in different situations, such as whether the individual has a single parathyroid adenoma or if multiple parathyroid glands are involved, if the imaging is for an initial surgical intervention versus a re-operation, and whether the individual has primary, secondary, or tertiary hyperparathyroidism.[1]

Parathyroid Incidentaloma (Neck-8.4)

NK.PT.0008.4.A
v1.0.2026

- A mass incidentally found on neck imaging that may represent an enlarged parathyroid gland should prompt laboratory testing including calcium and PTH levels.
  - If laboratory abnormalities suggest hyperparathyroidism, i.e., "functioning parathyroid incidentaloma", see **Hyperparathyroidism (NECK- 8.3)** for imaging recommendations.
  - If there are no laboratory abnormalities and diagnoses other than parathyroid incidentaloma are suspected, see **Neck Mass/Swelling/Adenopathy (NECK- 5.1)** for imaging recommendations.
  - Parathyroid nuclear scans are commonly requested for an evaluation of a parathyroid incidentaloma; however, the sensitivity of these scans are low in individuals with normal calcium/PTH and no clinical symptoms of primary hyperparathyroidism. Reliance on either a positive scan or negative scan to decide if surgery is medically necessary is not supported by current literature.
- If a parathyroid incidentaloma is suspected on imaging prior to planned thyroid surgery or other head/neck surgery, the following studies are medically necessary if ordered by the surgical team or any provider in consultation with the surgical team:
  - Parathyroid Planar Imaging (CPT® 78070), Parathyroid Planar Imaging with SPECT (CPT® 78071), or Parathyroid Planar Imaging with SPECT/CT (CPT® 78072) AND/OR Ultrasound (CPT® 76536) AND/OR 4D CT Neck without and with contrast (CPT® 70492)
- Ultrasound (US) Neck (CPT® 76536) is medically necessary annually if the mass was not removed surgically.

Background and Supporting Information

- "Parathyroid incidentalomas" include parathyroid adenomas found unexpectedly at the time of surgery or seen on ultrasound.
- Normal sized parathyroid glands (~6mm) are not usually identified by most imaging modalities, so enlargement warrants laboratory evaluation to rule out pathologic causes such as primary hyperparathyroidism or rarely parathyroid carcinoma.
- Sonographic imaging features of a parathyroid incidentaloma (ovoid, hypoechoic, well circumscribed and adjacent to but separate from the thyroid either posteriorly or inferiorly) may have overlap with perithyroidal lymph nodes and exophytic thyroid nodules in a multinodular goiter.
- The literature does report cases of pathologically confirmed parathyroid adenomas/ hyperplasia in individuals with normal serum calcium and PTH levels, so these enlarged parathyroid glands may represent an early stage of hyperparathyroidism.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

It is unclear what percentage of non-functioning PTIs become hyper-secreting over time, but many of these masses are surgically managed.

- Normally sized and normally functioning parathyroid glands do not take up sestamibi or tetrofosmin. The likelihood of a positive parathyroid nuclear scan is low in the setting of normal calcium and PTH levels.
- Parathyroid fine needle aspiration biopsy has been used historically; however, its diagnostic use is limited due to the potential for hemorrhage and fibrosis which make eventual surgical dissection and pathologic interpretation more difficult.

Evidence Discussion

- With the advent of high resolution CT scans, ultrasounds, and other imaging modalities, along with their widespread use as diagnostic modalities, parathyroid lesions are increasingly being incidentally found on these imaging studies.[1]
- The distinct features of parathyroid lesions are readily seen on ultrasound imaging.[1]
- If lab work does not indicate hyperfunctioning of the parathyroid gland, then these lesions can be monitored annually with ultrasound, as parathyroid nuclear scans have low sensitivity for detection in individuals with normal parathyroid function.[1]
- Parathyroid nuclear scans, 4D CT of the Neck, and Neck ultrasound studies can be used in evaluation of parathyroid incidentalomas found prior to a pending neck surgery to aid in preoperative evaluation, as determined by the surgical team.[1]

Imaging of the Larynx, Trachea, and Bronchus (Neck-9.1)

NK.TR.0009.1.A
v1.0.2026

- Initial evaluation for suspected laryngotracheal pathology:
  - Direct visualization of the upper airway (via laryngoscopy, with or without bronchoscopy), and can also include
  - Plain x-rays of the neck with or without chest x-ray
- To further evaluate definite abnormalities found on either of the above, including laryngotracheal, tracheal, or bronchial anomalies, foreign bodies or persistent segmental or lobar lung collapse:
  - CT Neck with contrast (CPT® 70491) **OR** CT Neck without contrast (CPT® 70490) **AND/OR**
  - CT Chest with contrast (CPT® 71260) **OR** CT Chest without contrast (CPT® 71250), depending on the anatomic level of the lesion.
    - MRI Orbit/Face/Neck without contrast (CPT® 70540) OR MRI Neck without and with contrast (CPT® 70543) is medically necessary as a supplement to CT Neck or CT Chest if additional assessment is needed.
    - See **Squamous Cell Carcinomas of the Head and Neck—Suspected/ Diagnosis (ONC-3.1)** for suspected laryngotracheal tumor.
- For suspected subglottic stenosis (SGS) after evaluation by a specialist or in consultation with a specialist who has directly visualized the upper airway:
  - CT Neck with contrast (CPT® 70491) **OR** CT Neck without contrast (CPT® 70490) is medically necessary.
- For obstructive physiology in the setting of tracheomalacia:
  - Expiratory HRCT (CPT® 71250) is medically necessary.

Background and Supporting Information

- Bronchoscopy can further evaluate the distal endobronchial tree.
- Suspected laryngotracheal disease can be identified by inspiratory or biphasic stridor and a characteristic flow-volume loop of PFTs.
- The visualization of tracheal or bronchial "inspissation" or thickening of secretions without an abnormality, is not a risk for malignancy.
- CT with multiplanar reformatting has proven comparable to rigid bronchoscopy with a 100% sensitivity and specificity of detecting SGS and for measuring length and grade of stenosis.

Click Here to Return to the Main TOC

Evidence Discussion

- Radiographs by means of neck and chest radiographs are sensitive for only those radioopaque foreign bodies but have value in providing information regarding other chest pathology such as presence of consolidation, atelectasis and bronchiectasis.[6]
- CT is more sensitive than x ray in identifying airway foreign bodies due to its higher resolution.[7]
- CT scan can rapidly and accurately identify laryngo-tracheo-bronchial abnormalities prior to bronchoscopy such as pneumonia, airway stenosis, atelectasis, effusion and consolidation.[7-9]
- CT provides a sensitivity of more than 96% and a specificity of more than 97% in comparison to bronchoscopy for detecting tracheomalacia. CT provides the advantage of simultaneously evaluating mediastinal, vascular and lung pathologies.[10]

Click Here to Return to the Main TOC

Neck Pain (Cervical) (Neck-10.1)

NK.NP.0010.1.A

v1.0.2026

- Neck pain is usually related to a specific process including pharyngitis, radiculopathy, adenopathy, mass, carotid dissection and torticollis, and therefore found elsewhere in these guidelines.
- For the evaluation of neck pain or other symptoms which may involve the cervical spine, including myelopathy and cervical radiculopathy, see Spine Imaging Guidelines .

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Torticollis and Dystonia (Neck-10.2)

NK.NP.0010.2.A
v1.0.2026

Older Child (beyond infancy) or Adult

- To identify fracture or malalignment in cases of trauma:
  - Initial evaluation of trauma (without a high-risk mechanism of injury–see **SP-3.2 Neck (Cervical Spine) Trauma**) is by plain radiographs of the cervical spine. If inconclusive:
    - CT Neck with contrast (CPT® 70491) **AND/OR**
    - CT Cervical Spine without contrast (CPT® 72125)
- In the clinical setting of cervical spine trauma with an associated neurologic deficit:
  - MRI Cervical Spine without contrast (CPT® 72141) is medically necessary.
- To evaluate for soft tissue or neurological cause in cases with no trauma history:
  - CT Neck with contrast (CPT® 70491), **AND/OR**
  - MRI Cervical Spine without contrast (CPT® 72141), **OR**
  - CT Cervical Spine without contrast (CPT® 72125)
    - Positive→ Further advanced imaging is not medically necessary if CT Neck or CT/MRI Cervical Spine has identified local cause.
    - Negative→ MRI Brain without and with contrast (CPT® 70553) to exclude CNS cause.

Evidence Discussion

- Plain radiography continues to be the primary imaging modality for the initial diagnosis of neck concerns in cases of trauma without high-risk mechanism of injury.[9,10]
- CT offers superior depiction of cortical bone and is more sensitive than radiographs in assessing facet degenerative disease, osteophyte formation, and other osseous structures.[9,10]
- Individuals with abnormal neurological findings benefit from MRI to help identify spinal cord abnormalities and soft tissue causes in the workup of dystonia and/or torticollis.[9,10]
- Risks associated with imaging include, but are not limited to, radiation exposure and contrast complications.[9,10]

Click Here to Return to the Main TOC

Eagle Syndrome (Neck-10.3)

NK.NP.0010.3.A
v1.0.2026

Also known as "calcified stylohyoid ligament", "elongation of styloid process", or "stylocarotid artery syndrome".

- **"Classic Eagle Syndrome"**
  - Typically seen in individuals after pharyngeal trauma or tonsillectomy
  - Characterized by ipsilateral dull, persistent pharyngeal pain, centered in the ipsilateral tonsillar fossa, that can be referred to the ear, and exacerbated by rotation of the head
  - Other symptoms may include dysphagia, sensation of foreign body in the throat, tinnitus, or cervicofacial pain.
  - If Eagle Syndrome is suspected on exam and/or lateral neck x-ray:
    - CT Maxillofacial with contrast (CPT® 70487) **OR** CT Maxillofacial without contrast (CPT® 70486) **AND/OR**
    - CT Neck with contrast (CPT® 70491) **OR** CT Neck without contrast (CPT® 70490)
- **"Stylocarotid Artery Syndrome"** (i.e., the anterior circulation equivalent of "bow hunter syndrome"—rotational vertebral artery occlusion syndrome)
  - It is characterized by the compression of the internal or external carotid artery (with their peri-vascular sympathetic fibers) by a laterally or medially deviated styloid process.
  - It is related to a pain along the distribution of the artery, which is provoked and exacerbated by rotation and compression of the neck.
  - It is not correlated with tonsillectomy.
  - If Stylocarotid Artery Syndrome is suspected on exam and/or lateral neck x-ray:
    - CT Maxillofacial with contrast (CPT® 70487) **AND/OR**
    - CT Neck with contrast (CPT® 70491)
    - Dynamic/Positional CTA (CPT® 70498) is also medically necessary to assess for concerns of vascular compression (see also **General Guidelines - CT and MR Angiography (CTA and MRA) (HD-1.5)** and **General Guidelines - Other Imaging Situations (HD-1.7)**
    - In cases of impingement of the internal carotid artery, there may be referred supraorbital pain and parietal headache. In cases of external carotid artery irritation, the pain radiates to the infraorbital region.
- CT scanning (and in particular, 3-D CT scanning) represents an extremely valuable imaging tool in individuals with Eagle syndrome. 3-D rendering (CPT® 76376 or CPT®

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

76377) is medically necessary as an add on to CT Neck (CPT® 70491 **or** CPT® 70490), if requested, for accurate evaluation of the styloid process in relation to its anatomic relationship with the other head and neck structures, in surgical planning. See **3D Rendering (Preface-4.1)**.

Background and Supporting Information

- Torticollis or cervical dystonia is an abnormal twisting of the neck resulting in head rotation. Its causes are many and may be congenital or acquired and caused by trauma, infection/inflammation, neoplasm and/or idiopathic. It occurs more frequently in children and on the right side (75%).
- Eagle syndrome is characterized by recurrent pain in the oropharynx and face due to an elongated styloid process or calcified stylohyoid ligament. The styloid process is a slender outgrowth at the base of the temporal bone, immediately posterior to the mastoid apex.

Evidence Discussion

- If Eagle syndrome is suspected on exam and/or lateral neck x-ray, CT Maxillofacial or CT Neck are medically necessary.[4,7]
- CT is the preferred modality for evaluation of bony structures and detection of abnormalities associated with calcifications.[13]
- Indications for cervicocerebral computed tomography angiography (CTA) or magnetic resonance angiography (MRA) of the head and neck vessels or include the diagnosis, characterization and/or surveillance of a variety of vascular conditions, including vascular compression of the internal or external carotid artery by an elongated styloid process (Eagle Syndrome).[6]
- Risks of CTA include exposure to ionizing radiation; thus, magnetic resonance angiography (MRA) is available as an alternative to reduce radiation exposure. In addition, MRA is an alternative for individuals with iodinated contrast allergies or other contraindications to iodinated contrast.[6,14]
- MRA, as an alternative modality, is noninvasive, and does not require iodinated contrast. Limitations include artifacts due to motion, slow or turbulent flow, susceptibility effects, and claustrophobia. Additionally, MRA may not be a feasible option for those with contraindications to MRI such as incompatible pacemakers, cochlear implants, neurostimulators or other devices. In these scenarios, CTA may be the appropriate alternative.[6,14,15]

Click Here to Return to the Main TOC

Neck Trauma (Neck-10.4)

NK.NP.0010.4.A

v1.0.2026

- CT Neck with contrast (CPT® 70491) OR CT Neck without contrast (CPT® 70490) is medically necessary in individuals with neck trauma who have an altered state of consciousness, distracting injuries or intoxication, midline tenderness to palpation, or neurological deficits.
- Penetrating neck trauma
  - CTA Neck (CPT® 70498) is medically necessary for evaluating vascular injury and/or aerodigestive injuries.
- Blunt neck trauma
  - For any evidence of blunt neck trauma, including but not limited to: neurologic deficit, infarction on CT Head, cervical seatbelt sign, and fractures of the skull, face, or spine, a CTA Neck (CPT® 70498) is medically necessary.
  - If CTA is negative but high clinical suspicion remains for esophageal injury, MRA Neck with contrast (CPT® 70548) OR MRA Neck without contrast (CPT® 70547) OR MRA Neck without and with contrast (CPT® 70549) is medically necessary.
- Laryngeal neck trauma
  - For any clinical suspicion of injury, CT Neck without contrast (CPT® 70490) is medically necessary.

Evidence Discussion

- CTA has high sensitivity and specificity for stable individuals with penetrating neck trauma.[18]
- CTA is the primary imaging modality to assess aerodigestive injuries from penetrating neck trauma. However, a high number of esophageal injuries are missed on CTA, so a negative CTA with suspicion for esophageal injury warrants additional testing.[16,19]
- MRA Neck can be useful to detect dissections and intramural hematoma from blunt neck trauma.[20]
- CT Neck without contrast is useful to assess laryngeal neck trauma, as it can assess the cartilaginous and bony components, as well as determine any fractures that may need stabilization.[21]

Background and Supporting Information

- For penetrating neck trauma, if diagnostic uncertainty remains after CTA Neck, follow-up tests may include ultrasound, esophagram, angiography, and triple endoscopy.

Salivary Gland Disorders (Neck-11.1)

NK.SG.0011.1.A
v1.0.2026

- **Xerostomia (Dry Mouth)**
  - Salivary Gland Nuclear Imaging (one of CPT® 78230, CPT® 78231, or CPT® 78232) is medically necessary for any one of the following:
    - Dry mouth and either:
      - Sjögren's syndrome
      - Sialadenitis
      - History of head or neck radiation therapy
      - History of cerebral palsy
      - Parotid mass to allow preoperative diagnosis of Warthin's tumor
- **Salivary Gland Stones, Sialadenitis or Stenosis**:
  - Sialography (contrast dye injection) under fluoroscopy is medically necessary to rule out a salivary duct stone or stricture, using
    - Post-sialography CT (CT Maxillofacial without contrast [CPT® 70486] for Stensen's duct of the parotid gland, which would be most common; **or** CT Neck without contrast [CPT® 70490] for the level of the Wharton's Duct); **or** post-sialography MRI (MRI Orbit/Face/Neck without contrast [CPT® 70540]) **OR**
  - CT Maxillofacial area with contrast (CPT® 70487) **OR**
  - CT Neck with contrast (CPT® 70491)
    - CT performed only without IV contrast (CPT® 70490) may be helpful in a small minority of cases, such as cases of follow-up for known salivary stones, or for post-sialography imaging, as described above **OR**
  - MRI Orbit/Face/Neck without and with contrast (CPT® 70543)
- **Parotid or Other Salivary Gland Mass**
  - The following are appropriate:
    - Ultrasound (CPT® 76536) is medically necessary as initial or additional imaging and does not need to be completed prior to the performance of advanced imaging.
    - MRI Orbit/Face/Neck without and with contrast preferred (CPT® 70543) **or** MRI Orbit/Face/Neck without contrast (CPT® 70540) **OR**
    - CT Neck with contrast (CPT® 70491) preferred **or** CT Maxillofacial area with contrast (CPT® 70487)
- **Repeat Imaging (CT or MRI, as above)**
  - There is currently no standard timeframe for repeat advanced imaging to follow known benign pathology of the salivary gland that has been resected—partially

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

or completely, or only observed. This holds true even if the salivary lesion has the potential for recurrence or malignant transformation (i.e., pleomorphic adenoma).
  - Repeat advanced imaging, as requested by the surgeon or those in consultation with the surgical team, is medically necessary if relevant history and exam demonstrate signs:
    - concerning for complications of surgery, or
    - recurrence or progression of neoplasm/lesion

Evidence Discussion

- Current history and comprehensive head & neck exam are required prior to any advanced imaging for suspected salivary gland pathology.[1]
- CT should be performed with IV contrast to distinguish vessels from lymph nodes and to confirm if a mass is hypervascular. *Dual-phase CT imaging (without and with IV contrast) is not medically necessary*.[2]
  - CT performed only without IV contrast may be helpful in a small minority of cases including cases of follow-up for known salivary stones or post-sialography studies.
- A recent study in the American Journal of Neuroradiology comparing contrast enhanced and non-contrast enhanced CT in the evaluation of sialolithiasis demonstrated excellent sensitivity and specificity with no false-positive results using contrast-enhanced CT alone (without the addition of non-contrasted images for comparison).[3] The sensitivity of contrast-enhanced CT is 96-98%, and the specificity is 88-100%.[7] Benefits of initial only contrast-enhanced CT include better evaluation of the ductal system, improved soft tissue contrast in assessing salivary masses and decreased radiation dose (compared to dual phase CT imaging (without and with IV contrast)).[3]
- The preferred modality to evaluate suspected parotid lesions is MRI of the face and/or neck with and without IV contrast. It can provide comprehensive information about the full extent of the mass (i.e., deep lobe involvement) and other local invasion (such as perineural tumor spread and possible extension into the temporal bone).[4]

Definitions (Neck-12.0)

NK.ST.0012.0.A
v1.0.2026

- Hoarseness – Altered voice quality reported by the individual
- Dysphagia – Disordered or impaired swallowing i.e., food impactions, globus sensation, choking/aspiration, regurgitation (see **Dysphagia and Upper Digestive Tract Disorders (Neck-3.1)**)
- Odynophagia – Painful swallowing

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Sore Throat/Throat Pain/Odynophagia (Neck-12.1)

NK.ST.0012.1.A
v1.0.2026

- See **Dysphagia and Upper Digestive Tract Disorders (Neck-3.1)** for dysphagia as the primary symptom.
- Sore Throat/Throat Pain/Odynophagia
  - Uncomplicated viral or streptococcal pharyngitis with sore throat
    - Imaging studies are not medically necessary. See **Neck Mass/Swelling/ Adenopathy (Neck-5.1)** for suspected complications of pharyngitis/tonsillitis, such as a cervical space abscess.
  - Postoperative throat pain or odynophagia after head and neck procedure with suspected complication of procedure:
    - CT Neck with contrast (CPT® 70491)
  - Sore throat/throat pain/odynophagia that is persistent or progressive for two or more weeks, in spite of any treatment measures or observation:
    - Initial evaluation is laryngoscopy
      - If the initial laryngoscopy is abnormal, or if it is negative, and if there is a continued concern for an occult lesion within the pharynx due to any red flag symptoms (weight loss, referred otalgia, hoarseness, hemoptysis, and/or unilateral presentation of symptoms):
        - CT Neck with contrast (CPT® 70491) **OR**
        - MRI Orbit/Face/Neck without and with contrast (CPT® 70543)
      - Alarm symptoms of persistent unilateral throat pain or odynophagia with ipsilateral referred otalgia is especially suspicious for a submucosal tumor of the head and neck (versus more distal esophageal pathology).
      - If subjective dysphagia AND odynophagia are both present and the initial laryngoscopy and neck exam are normal (i.e., no cervical space abscess or post-surgical complication is suspected), and no red flag symptoms are present, then barium esophagram (or GI upper endoscopy) is medically necessary prior to the advanced imaging studies of the neck listed above.

Evidence Discussion

- Both CT and MRI can be used to delineate masses and provide cross sectional visualization of lesions that are deep to the mucosal surface. CT has the advantage to being readily available, requiring less time and less expense when compared to MRI.[7,8]

Hoarseness (Neck-12.2)

NK.ST.0012.2.A

v1.0.2026

- Laryngoscopy is the primary diagnostic modality for evaluating individuals with hoarseness. Imaging studies, including CT and MRI, are not medically necessary in most individuals with hoarseness because most hoarseness is self-limited or caused by pathology that can be identified by laryngoscopy alone.
- The need for advanced imaging is based upon abnormal findings upon laryngoscopy, such as:
  - Immobile or partially mobile vocal cord [see **Recurrent Laryngeal Nerve Palsy (NECK-7.1)**]
  - Any growth, asymmetry, ulceration, or other suspected neoplasm of the glottis or supraglottis [see **Neck Mass/Swelling/Adenopathy (Neck 5.1)**; see also **ONC-3.0-3.4**].

General Guidelines (ONC-1.0)

ON.GG.0001.0.A

v3.0.2026

- A relevant clinical evaluation or meaningful contact (telephone call, electronic mail or messaging) should be performed prior to considering advanced imaging, unless the individual is undergoing guideline-supported scheduled off therapy surveillance evaluation or cancer screening. The clinical evaluation may include a relevant history and physical examination, including biopsy, appropriate laboratory studies, and results of non-advanced or advanced imaging modalities.
- Unless otherwise stated in the disease-specific guideline, a histological confirmation of malignancy (or recurrence) and the stage of disease is required to perform a medical necessity review of the requested imaging.
- Generally, the studies listed in the disease-specific sections reflect the studies supported by current literature and research for that condition. If a study is not listed, then it is not medically necessary.
- Routine imaging of brain, spine, neck, chest, abdomen, pelvis, bones, or other body areas is not medically necessary except where explicitly stated in a diagnosis-specific guideline section, or if one of the following applies:
  - Known prior disease involving the requested body area
  - New or worsening symptoms or physical exam findings involving the requested body area (including non-specific findings such as ascites or pleural effusion)
  - New finding on basic imaging study such as plain x-ray or ultrasound
  - New finding on adjacent body area CT/MRI study (i.e., pleural effusion observed on CT Abdomen)
- Unless otherwise stated in the disease-specific guideline, advanced imaging of asymptomatic individuals is not routinely medically necessary without signs or symptoms of systemic involvement of cancer.
- Repeat imaging studies are not generally medically necessary unless there is evidence of disease progression, recurrence of disease, and/or the repeat imaging will affect an individual's clinical management.
- Conventional imaging performed prior to diagnosis should not be repeated unless there is a delay of at least 6 weeks since previous imaging and treatment initiation or there are new or significantly worsening clinical signs or symptoms.
- If an individual is late for a specified imaging, the imaging may be approved late. However, the interval between the late imaging and the subsequent imaging must adhere to the interval in the disease-specific guidelines.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Phases of Oncology Imaging and General Phase-Related Considerations

The following provides general clarity regarding the categories used to describe the phases of imaging throughout these guidelines.

- Screening
  - Imaging requested for individuals at increased risk for a particular cancer in the absence of known clinical signs or symptoms
- Suspected diagnosis
  - Imaging requested to evaluate a suspicion of cancer, prior to histological confirmation
- Initial work-up and staging
  - Imaging requested after biopsy confirmation and prior to starting specific treatment
- Treatment response
  - Imaging performed during active treatment with chemotherapy, targeted therapy, immunotherapy, radiation therapy, or endocrine therapy. Can be curative or non-curative.
- Restaging of locally treated lesions
  - Imaging performed to evaluate response to primary or metastatic lesion(s) following lesion directed therapy (e.g., cryotherapy, ablation, radioembolization, chemoembolization, radiation therapy).
- Restaging/suspected recurrence
  - Imaging requested when there is suspicion for progression or recurrence of known cancer based on clinical signs or symptoms, laboratory tests, or basic imaging studies.
- Surveillance
  - Imaging performed in individuals who are asymptomatic or have chronic stable symptoms, have no clinical suspicion of change in disease status, and are not receiving active anti-tumor treatment or are receiving maintenance treatment.
  - In malignancies that support post-operative imaging through Restaging/ Recurrence or Surveillance guidelines, imaging interval is determined using both parameters. Surveillance imaging should be done using date of post-operative imaging. If post-operative imaging was done not, use most appropriate guideline.

The table below provides descriptions of treatment phases, their definitions, and general timeframes.

Treatment Phase	Phase Definition	Imaging Timeframe
After definitive local therapy of primary tumor	Treatment intended to be curative typically using a combination of surgery, radiation therapy, and chemotherapy	Follow surveillance guidelines

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Treatment Phase	Phase Definition	Imaging Timeframe
During/after neoadjuvant chemotherapy	Treatment given prior to definitive intended curative therapy (usually surgery and/or radiation therapy based), to shrink the cancer to make the definitive curative therapy more effective	Follow initial work-up/staging or restaging/recurrence guidelines
During adjuvant chemotherapy	Adjuvant is given after the primary cancer treatment (primary treatment is usually surgery or radiation) with the goal of destroying any remaining cancer cells that cannot be visualized but may still be present, to reduce the risk of recurrence and improve cure/ survival rates beyond initial curative treatments (e.g., colorectal, breast).	Follow surveillance guidelines
After ablative therapy	Minimally invasive medical procedure that destroys abnormal tissue (cancer cells) using heat, cold or other methods, often used as an alternative to surgery or in conjunction with other treatments. Ablative therapy can be considered curative or palliative depending on numerous factors such as other sites of disease, cancer subtype, and ablative technique used.	See disease-specific guidelines

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Treatment Phase	Phase Definition	Imaging Timeframe
Chemotherapy or immunotherapy for active disease	• Measurable disease: Cancerous lesions that can be accurately measured in size to allow for assessment of tumor response. Solid lesions need to be 1cm or greater while lymph nodes should be 1.5cm or greater (short axis) • Non-measurable active disease: Lesions that cannot be accurately measured based on size (see above) in addition to lesions such as bone, pleural effusions, ascites, and carcinomatosis. • Active disease: Cancer thought to be "active" whether it is measurable or non-measurable. For lesions that are not clear (i.e., due to small size, chronically stable, not proven to be malignant), provider discretion is to be used to include modality.	Every 2 cycles (generally every 6 to 8 weeks)
During endocrine/ hormonal therapy alone for active disease	E.g., tamoxifen, letrozole, anastrozole, exemestane	Every 3 months (12 weeks)
Active disease on maintenance therapy	Maintenance therapy is given to help keep cancer from coming back after it has shrunk or disappeared following initial therapy and may be given for a finite or indefinite timeframe.	See disease-specific guidelines
Active metastatic disease being monitored off therapy		Every 3 months (12 weeks)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Treatment Phase	Phase Definition	Imaging Timeframe
Metastatic disease in complete response on or off therapy	Defined as all measurable and non-measurable disease has disappeared (to include normalized tumor markers if applicable) and rarely translates into cure but remission can be sustained for years	• Once complete remission (CR) has been achieved, frequency of imaging should be no sooner than every 3 months and continue for up to 5 years from the time of CR • Follow surveillance guidelines
Metastatic disease in complete response due to definitive treatment (surgery, XRT, ablation) agnostic to histology	Defined as all measurable disease has been definitively removed/treated but individual is not considered cured.	See disease-specific guideline; if not in guideline, determined on a case-by-case basis.

- Advanced imaging is not medically necessary for evaluation of in situ or non-invasive cancers or cancer surveillance after complete surgical removal of primary disease unless otherwise stated in the cancer-specific guidelines.
- Advanced imaging is not medically necessary for monitoring disease in individuals who choose to not receive standard oncologic therapy but may be receiving alternative therapies or palliative care and/or hospice. All advanced imaging medically necessary for initial staging of the specific cancer type can be approved once when the individual is considering initiation of a standard therapeutic approach (surgery, chemotherapy, or radiation therapy).
- Brain imaging is performed for signs or symptoms of brain disease
  - MRI Brain without and with contrast (CPT® 70553) is the recommended study for evaluation of suspected or known brain metastases. If a non-contrast CT head shows suspicious lesion, MRI Brain is medically necessary to further characterize the lesion.
  - CT without and with contrast (CPT® 70470) is medically necessary when MRI is contraindicated or not available, or if there is skull bone involvement.
  - Certain malignancies including, but not limited to, melanoma and lung cancer have indications for brain imaging for asymptomatic individuals.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - If stage IV disease is demonstrated elsewhere or if systemic disease progression is noted, refer to disease specific guidelines.
  - Initiation of angiogenesis therapy is not an indication for advanced imaging of the brain in asymptomatic individuals (Avastin/Bevacizumab; <3% risk of bleeding and <1% risk of serious bleeding).
- Bone Scan:
  - Primarily used for evaluation of bone metastases in individuals with solid malignancies.
  - Bone scan MAY be medically necessary in individuals with history of malignancy, including bone pain, rising tumor markers, elevated alkaline phosphatase or in individuals with primary bone tumor.
  - For evaluation of suspected or known bony metastases, CPT® 78306 (Nuclear bone scan whole body), is medically necessary.
  - Radiopharmaceutical Localization scan SPECT (CPT® 78803 or CPT® 78831) or SPECT/CT (CPT® 78830 or CPT® 78832) is medically necessary as an add-on test for further evaluation of a specific area of interest.
  - CPT® codes 78300 (Nuclear bone scan limited), 78305 (Nuclear bone scan multiple areas) or 78315 do not have any indications in oncology nuclear medicine imaging.
- Bone scan supplemented by plain x-rays are the initial imaging modalities for suspected malignant bone pain. For specific imaging indications, see also:
  - **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)**
  - **Bone (Non-Vertebral) Metastases (ONC-31.5)**
  - **Spinal/Vertebral Metastases (ONC-31.6)**
  - **Carcinoma of Unknown Primary Site (ONC-31.7)**
- Advanced imaging used for radiation therapy treatment planning should not be authorized using any of the diagnostic imaging codes for CT, MRI, or PET.
  - Advanced imaging performed in support of radiation therapy treatment planning should be reported with CPT® 76498 for Unlisted MRI or CPT® 76497 for Unlisted CT scan.
- Delay PET/CT for at least 12 weeks after completion of radiation treatment, unless required sooner for imminent surgical resection.
- PET/CT may be medically necessary prior to biopsy in order to determine a more favorable site for biopsy when a prior biopsy was nondiagnostic or a relatively inaccessible site is contemplated which would require invasive surgical intervention for biopsy attempt.
- PET/CT is medically necessary if:
  - conventional imaging (CT, MRI or bone scan) reveals findings that are inconclusive or negative, with continued suspicion for active disease

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Unless specified in diagnosis-specific guideline section, PET/CT Imaging is NOT medically necessary for:
  - infection, inflammation, trauma, post-operative healing, granulomatous disease, rheumatological conditions
  - concomitant use with separate diagnostic CT studies
  - conclusive evidence of distant or diffuse metastatic disease on recent conventional imaging studies
  - metastatic disease in the central nervous system (CNS)
  - lesions less than 8mm in size
  - follow up after localized therapy (e.g., radiofrequency ablation, embolization, stereotactic radiation, etc.)
  - rare malignancies, due to lack of available evidence regarding the diagnostic accuracy of PET in rare cancers
  - surveillance
    - Serial monitoring of individuals who are not currently receiving anti-tumor treatment or are receiving maintenance treatment
    - Serial monitoring of FDG avidity until resolution.
    - PET/CT avidity in a residual mass at the end of planned therapy is not an indication for PET/CT imaging during surveillance.
    - Residual mass that has not changed in size since the last conventional imaging does not justify PET imaging
- Unless otherwise specified for a specific cancer type, once PET has been documented to be negative for a given individual's cancer or all PET-avid disease has been surgically resected, PET is not medically necessary for continued disease monitoring or surveillance.
- PET/MRI is generally not medically necessary for a vast majority of oncologic conditions due to lack of standardization in imaging technique and interpretation. However, it may be approved in select circumstances when the following criteria are met:
  - The individual meets condition-specific guidelines for PET/MRI OR
  - The individual meets ALL of the following:
    - The individual meets guideline criteria for PET/CT, AND
    - PET/CT is not available at the treating institution, AND
    - The provider requests PET/MRI in lieu of PET/CT
  - When the above criteria are met, PET/MRI may be reported using the code combination of PET Whole-Body (CPT® 78813) and MRI Unlisted (CPT® 76498). All other methods of reporting PET/MRI are inappropriate.
    - When clinically appropriate, diagnostic MRI codes may be medically necessary at the same time as the PET/MRI code combination.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- The specific radiotracer planned to be used with PET/CT imaging is required to perform a medical necessity review. Indications for PET/CT imaging using non-FDG radiotracers are listed in diagnosis-specific guidelines.
  - Supported radiotracers:
    - ^{18}F-FDG
    - ^{68}Gallium DOTATATE (NETSPOT®) for low-grade neuroendocrine tumors and medullary thyroid cancer
    - ^{64}Cu-DOTATATE (DETECTNET®) for low-grade neuroendocrine tumors
    - ^{68}Ga-DOTA-TOC for low-grade neuroendocrine tumors
    - ^{11}C Choline for prostate cancer
    - ^{18}F-Fluciclovine (AXUMIN®) for prostate cancer
    - ^{68}Ga PSMA-11 for prostate cancer
    - ^{18}F Piflufolastat (Pylarify®) for prostate cancer
    - ^{68}Ga Gozetotide (Illuccix®, Locametz®, and Gozellix®) for prostate cancer
    - ^{18}F Flotufolastat (Posluma®) for prostate cancer
    - ^{18}F Fluoroestradiol (Cerianna®) for breast cancer
    - ^{18}F Na Fluoride PET bone scan for breast cancer and prostate cancer
  - Unsupported radiotracers:
    - PET/CT imaging using isotopes other than those specified above
- Octreotide scan:
  - Specific for low and intermediate grade neuroendocrine tumors which express specific cell surface somatostatin receptors. See cancer specific guidelines for recommended use.
  - One of the following codes may be approved when Octreotide scan is requested:
  - CPT® 78802 (Radiopharmaceutical localization of tumor whole-body single day study)
  - CPT® 78804 (Radiopharmaceutical localization of tumor whole-body two or more days)
  - In addition to one of the above CPT codes, CPT® 78803 (Radiopharmaceutical localization of tumor SPECT), SPECT CPT® 78831, or hybrid SPECT/CT (CPT® 78830 or 78832) may be approved as an add-on test for further evaluation of a specific area of interest.

Clinical Trials

- Similar to investigational and experimental studies, clinical trial imaging requests will be considered to determine whether they meet these evidence-based guidelines.
- Imaging studies which are inconsistent with established clinical standards, or are requested for data collection and not used in direct clinical management are not medically necessary.

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

Key Principles (ONC-1.1)

ON.GG.0001.1.A
v3.0.2026

AGE APPROPRIATE GUIDELINES	
Age of Individual	**Appropriate Imaging Guidelines**
≥18 years old at initial diagnosis	• General Oncology Imaging Guidelines, except where directed otherwise by a specific guideline section
<18 years old at initial diagnosis	• Pediatric and Special Populations Oncology Imaging Guidelines, except where directed otherwise by a specific guideline section
15 to 39 years old at initial diagnosis (defined as Adolescent and Young Adult (AYA) oncology individuals)	• When unique guidelines for a specific cancer type exist only in either General Oncology or Pediatric and Special Populations Oncology, AYA individuals should be imaged according to the guideline section for their specific cancer type, regardless of the individual's age • When unique guidelines for a specific cancer type exist in both General Oncology and Pediatric and Special Populations Oncology, AYA individuals should be imaged according to the age rule in the previous bullet

- Conventional Imaging (mostly CT, sometimes MRI or bone scan) of the affected area(s) drives much of initial and re-staging and surveillance. PET is not medically necessary for surveillance imaging unless specifically stated in the diagnosis-specific guideline sections.
- Brain imaging is performed for signs or symptoms of brain disease.
  - MRI Brain without and with contrast (CPT® 70553) is the preferred study for evaluation of suspected or known brain metastases.
  - MRI Brain without and with contrast (CPT® 70553) is medically necessary if a non-contrast CT Head shows suspicious lesion.
  - CT Head without and with contrast (CPT® 70470) is medically necessary when MRI is contraindicated or not available, or if there is skull bone involvement.
  - Initiation of angiogenesis therapy is not an indication for advanced imaging of the brain in asymptomatic individuals (Avastin/Bevacizumab; <3% risk of bleeding and <1% risk of serious bleeding).

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Individuals receiving cardiotoxic chemotherapy (such as doxorubicin, trastuzumab, pertuzumab, mitoxantrone, etc.) may undergo cardiac evaluation – at baseline and for monitoring while on active therapy.
  - See: **Oncologic Indications for Cancer Therapeutics-Related Cardiac Dysfunction (CTRCD) (CD-12.1)** in the Cardiology Imaging Guidelines
- CTA or MRA of a specific anatomic region is medically necessary when requested for surgical planning when there is suspected vascular proximity to proposed resection margin.
- Screening adults (≥18 years) with a diagnosis of Li-Fraumeni Syndrome (LFS) for malignancy with a Whole-Body MRI (CPT® 76498) is medically necessary on an annual basis. Annual Brain MRI (CPT® 70553) may be performed as part of Whole-Body MRI or as a separate exam. Due to lack of standardization of technique, interpretation, and availability of Whole-Body MRI, individuals with LFS are encouraged to participate in clinical trials.

Use of Contrast

- CT imaging should be performed with contrast for known or suspected body regions, unless contraindicated.
  - Shellfish allergy is not a contraindication to contrast. Individuals with known shellfish allergy do not have contrast reaction any more often than other atopic individuals or individuals with other food allergies.
  - For iodinated contrast dye allergy, either CT scans without contrast or MRI scans without and with contrast are medically necessary.
  - If CT scanning is medically necessary in an individual with known contrast allergy, CT with contrast may be considered to be safely performed following prednisone pre-medication over a 24-hour period prior to the study.
- For individuals with renal insufficiency which precludes contrast use, CT without contrast appropriate disease-specific areas is medically necessary. Further imaging (such as MRI) is medically necessary if non-contrast CT results are inconclusive.
- Severe renal insufficiency (i.e., an eGFR less than 30) is a contraindication for an MRI using a gadolinium-based contrast agent (GBCA) as well. In individuals with eGFR greater than 40, GBCA administration can be safely performed. GBCA administered to individuals with acute kidney injury or severe chronic kidney disease can result in a syndrome of nephrogenic systemic fibrosis (NSF), but GBCAs are not considered nephrotoxic at dosages approved for MRI.
- Gadolinium deposition has been found in individuals with normal renal function following the use of gadolinium based contrast agents (GBCAs).
  - The U.S. Food and Drug Administration (FDA) is investigating the risk of brain deposits following repeated use of GBCAs.
  - The FDA has noted that, “It is unknown whether these gadolinium deposits are harmful or can lead to adverse health effects.” and have recommended:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - To reduce the potential for gadolinium accumulation, health care professionals should consider limiting GBCA use to clinical circumstances in which the additional information provided by the contrast is necessary.
  - Health care professionals are also urged to reassess the necessity of repetitive GBCA MRIs in established treatment protocols.

Radiation Exposure

- The use of MRI in place of CT scans to reduce risk of secondary malignancy from radiation exposure during CT is not supported by the peer-reviewed literature. Unless otherwise specified in the Guidelines, MRI in place of CT scans for this purpose alone is not medically necessary. In some instances (i.e., testicular cancer surveillance), MRI may be considered inferior to CT scans.

Proprietary Information of UnitedHealthcare.

Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)

ON.GG.0001.3.A

v3.0.2026

- This section does not apply to PET imaging. PET imaging considerations can be found in **PET Imaging in Oncology (ONC-1.4)**
- Bone Scan:
  - Primarily used for evaluation of bone metastases in individuals with solid malignancies.
  - Indications for bone scan in individuals with history of malignancy include – bone pain, rising tumor markers, elevated alkaline phosphatase or in individuals with primary bone tumor.
  - For evaluation of suspected or known bony metastases, CPT® 78306 (Nuclear bone scan whole-body), is medically necessary.
    - Radiopharmaceutical Localization scan SPECT (CPT® 78803 or CPT® 78831) or SPECT/CT (CPT® 78830 or CPT® 78832) is medically necessary as an add-on test for further evaluation of a specific area of interest or clinically suspected lesions with negative whole body bone scan or documented bone metastasis in the setting of inconclusive or negative findings.
  - CPT® codes 78300 (Nuclear bone scan limited), 78305 (Nuclear bone scan multiple areas) or 78315 do not have any indications in oncology nuclear medicine imaging.
- Octreotide scan:
  - Specific for low and intermediate grade neuroendocrine tumors which express specific cell surface somatostatin receptors. See cancer specific guidelines for recommended use.
  - One of the following codes may be approved when Octreotide scan is requested:
    - CPT® 78802 (Radiopharmaceutical localization of tumor whole-body single day study)
    - CPT® 78804 (Radiopharmaceutical localization of tumor whole-body two or more days)
  - In addition to one of the above CPT codes, CPT® 78803 (Radiopharmaceutical localization of tumor SPECT), SPECT CPT® 78831, or hybrid SPECT/CT (CPT® 78830 or 78832) may be approved as an add-on test for further evaluation of a specific area of interest.
- Bone marrow imaging:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - This study is rarely performed for evaluation of the entire bone marrow in conditions like myeloproliferative disorders, sickle cell bone infarct or ischemia, avascular necrosis or myeloma.
  - The correct CPT code for this study is CPT® 78104 (Diagnostic Nuclear Medicine Procedures on the Hematopoietic, Reticuloendothelial and Lymphatic System).
- Brain imaging SPECT with Technetium-99m or thallium-201 (CPT® 78803 or CPT® 78830):
  - Immunocompromised individuals with mass lesion detected on CT or MRI for differentiation between lymphoma and infection
  - In distinguishing recurrent brain tumor from radiation necrosis
- Radiopharmaceutical localization of tumor or distribution of radiopharmaceutical agent(s):
  - CPT® 78800, CPT® 78801, CPT® 78802, CPT® 78804, CPT® 78803, CPT® 78831 (SPECT), or CPT® 78830 or CPT® 78832 (SPECT/CT)
  - for evaluation of fever of unknown origin and osteomyelitis
  - for suspected infections such as infected central lines, grafts or shunts
- Gallium Isotope Scan:
  - Radiopharmaceutical Localization of tumor (CPT® 78800, CPT® 78801, CPT® 78802, CPT® 78803, or CPT® 78804), SPECT CPT® 78831, or hybrid SPECT/CT CPT® 78830 or 78832
  - This may be rarely used in place of PET/CT scan when PET/CT scan not available and PET/CT is indicated by guidelines for lymphoma, sarcoma, melanoma or myeloma.

PET Imaging in Oncology (ONC-1.4)

ON.GG.0001.4.A
v3.0.2026

- CPT codes:
  - PET imaging in oncology should use PET/CT fusion (CPT® 78815 or CPT® 78816). Unbundling PET/CT imaging into separate PET and diagnostic CT codes is otherwise not supported.
  - The decision whether to use skull base to mid-femur (“eyes to thighs”) procedure code for PET (CPT® 78812 or CPT® 78815) or whole-body PET (CPT® 78813 or CPT® 78816) is addressed in the diagnosis-specific guideline sections.
  - ”Limited area” protocol is done infrequently, but may be considered, and is reported with PET (CPT® 78811) or for PET/CT (CPT® 78814).
- Radiotracers:
  - Unless specified otherwise, the term “PET” refers to ^{18}F-FDG-PET and PET/CT fusion studies.
  - Indications for PET/CT imaging using non-FDG radiotracers are listed in diagnosis-specific guidelines. The indications may be as follows:
- Supported radiotracers:
  - ^{18}F-FDG
  - ^{68}Gallium DOTATATE (NETSPOT®) for low-grade neuroendocrine tumors and medullary thyroid cancer
  - ^{64}Cu-DOTATATE (DETECTNET®) for low-grade neuroendocrine tumors
  - ^{68}Ga-DOTA-TOC for low-grade neuroendocrine tumors
  - ^{11}C Choline for prostate cancer
  - ^{18}F-Fluciclovine (AXUMIN®) for prostate cancer
  - ^{68}Ga PSMA-11 for prostate cancer
  - ^{18}F Piflufolastat (Pylarify®) for prostate cancer
  - ^{68}Ga Gozetotide (Illuccix®, Locametz®, and Gozellix®) for prostate cancer
  - ^{18}F Flotufolastat (Posluma®) for prostate cancer
  - ^{18}F Fluoroestradiol (Cerianna®) for breast cancer
  - ^{18}F Na Fluoride PET bone scan for breast cancer and prostate cancer
- Unsupported radiotracers:
  - PET/CT imaging using isotopes other than those specified above

Proprietary Information of UnitedHealthcare.

CPT/ HCPCS Code	Code Description	Brand or common name	Guideline Section and Cancer Type
A9552	^{18}F Fluoro deoxyglucose	FDG	Various guideline sections where PET is indicated
A9580	^{18}F Sodium fluoride	N/A	ONC-11: Breast Cancer, ONC-19: Prostate Cancer
A9587	^{68}Ga-68 Dotatate	NETSPOT®	ONC-15: Low-grade neuroendocrine tumors, ONC-6: Medullary thyroid cancer
A9515	^{11}C Choline	N/A	ONC-19, Prostate Cancer
A9588	^{18}F-Fluciclovine	AXUMIN®	ONC-19, Prostate Cancer
A9593 A9594	^{68}Ga PSMA-11	N/A	ONC-19, Prostate Cancer
A9595	^{18}F Piflufolastat	Pylarify®	ONC-19, Prostate Cancer
A9596	^{68}Ga Gozetotide	Illuccix®	ONC-19, Prostate Cancer
A9800	^{68}Ga Gozetotide	Locametz®	ONC-19, Prostate Cancer
A9616	^{68}Ga Gozetitide	Gozellix®	ONC-19, Prostate Cancer
A9608	^{18}F Flotufolastat	Posluma®	ONC-19, Prostate Cancer
A9591	^{18}F Fluoroestradiol	Cerianna®	ONC-11, Breast Cancer
A9592	^{64}Cu Copper dotatate	Detectnet®	ONC-15, Low-grade neuroendocrine tumors
C9067	^{68}Ga Gallium-DOTA-TOC	N/A	ONC-15, Low-grade neuroendocrine tumors

- Unless specified in diagnosis-specific guideline section, PET/CT Imaging is NOT medically necessary for:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- infection, inflammation, trauma, post-operative healing, granulomatous disease, rheumatological conditions
- concomitant use with separate diagnostic CT studies
- conclusive evidence of distant or diffuse metastatic disease on recent conventional imaging studies
- metastatic disease in the central nervous system (CNS)
- lesions less than 8mm in size
- follow up after localized therapy (i.e., radiofrequency ablation, embolization, stereotactic radiation, etc.)
- rare malignancies, due to lack of available evidence regarding the diagnostic accuracy of PET in rare cancers
- surveillance:
  - Serial monitoring of individuals who are not currently receiving anti-tumor treatment or are receiving maintenance treatment
  - Serial monitoring of FDG avidity until resolution.
  - PET/CT avidity in a residual mass at the end of planned therapy is not an indication for PET/CT imaging during surveillance.
  - Residual mass that has not changed in size since the last conventional imaging does not justify PET imaging
- Unless otherwise specified for a specific cancer type, once PET has been documented to be negative for a given individual's cancer or all PET-avid disease has been surgically resected, PET should not be used for continued disease monitoring or surveillance.

- PET/CT is medically necessary if:
  - Conventional imaging (CT, MRI or bone scan) reveals findings that are inconclusive or negative, with continued suspicion for recurrence.
  - The individual is undergoing salvage treatment for a recurrent solid tumor with residual measurable disease on conventional imaging and confirmed repeat negative PET imaging will allow the individual to transition from active treatment to surveillance.
  - PET/CT may be considered prior to biopsy in order to determine a more favorable site for biopsy when a prior biopsy was nondiagnostic or a relatively inaccessible site is contemplated which would require invasive surgical intervention for biopsy attempt.
- PET/CT for rare malignancies is not covered by these guidelines due to lack of available evidence regarding diagnostic accuracy of PET/CT in the majority of rare cancers. Conventional imaging studies should be used for initial staging and treatment response for these diagnoses. PET/CT is medically necessary if all of the following apply:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - Conventional imaging (CT, MRI or bone scan) reveals equivocal or suspicious findings.
  - No other specific metabolic imaging (MIBG, octreotide, technetium, etc.) is appropriate for the disease type.
  - The submitted clinical information describes a specific decision regarding the individual's care that will be made based on the PET/CT results.
- Delay PET/CT for at least 12 weeks after completion of radiation treatment, unless required sooner for imminent surgical resection.
- PET mammography (PEM, generally reported with CPT® 78811) is considered experimental and investigational at this time.
- PET/MRI is generally not medically necessary for a vast majority of oncologic conditions due to lack of standardization in imaging technique and interpretation. However, it may be approved in select circumstances when the following criteria are met:
  - The individual meets condition-specific guidelines for PET/MRI OR
  - The individual meets ALL of the following:
    - The individual meets guideline criteria for PET/CT, AND
    - PET/CT is not available at the treating institution, AND
    - The provider requests PET/MRI in lieu of PET/CT
  - When the above criteria are met, PET/MRI may be reported using the code combination of PET Whole-Body (CPT® 78813) and MRI Unlisted (CPT® 76498). All other methods of reporting PET/MRI are inappropriate.
    - When clinically appropriate, diagnostic MRI codes may be indicated at the same time as the PET/MRI code combination.

Unlisted Procedure Codes in Oncology (ONC-1.5)

ON.GG.0001.5.A

v3.0.2026

- There is often no unique procedure code for a service performed solely for treatment planning purposes. AMA instructions in the CPT state that if no specific code exists for a particular service, the service is reported with an unlisted code.
- Advanced imaging being used for radiation therapy treatment planning should not be authorized using any of the diagnostic imaging codes for CT, MRI or PET. Advanced imaging performed in support of radiation therapy treatment planning should be reported with:
  - **CPT® 76498 for Unlisted MRI** – when MRI will be used for treatment planning of radiation therapy to be delivered ONLY to the brain, prostate and cervix. The use of this code for radiation treatment planning of any other cancers/body parts not listed above may be reviewed on a case-by-case basis. Also on a case-by-case basis, an additional diagnostic study may be medically necessary if there is an additional clinical question requiring reading and interpretation of the study by a diagnostic radiologist (i.e., the study is not used exclusively for radiation treatment planning).
  - **CPT® 76497 for Unlisted CT** – may NOT be used for radiation treatment planning. CT imaging performed in support of radiation therapy treatment planning is bundled in with the concurrent radiation treatment authorization codes and a separate authorization for treatment planning is not required.
  - Imaging associated with image-directed biopsy should be reported with the corresponding interventional codes. See also: **CT-, MR-, or Ultrasound-Guided Procedures (Preface-4.2)** in the Preface Imaging Guidelines.
  - For advanced imaging used solely for the purpose of Surgical planning, see: **Unlisted Procedures/Therapy treatment planning (Preface-4.3)** in the Preface Imaging Guidelines

Primary Central Nervous System Tumors – General Considerations (ONC-2.1)

ON.CN_0002.1.A
v3.0.2026

- This guideline section applies to primary CNS tumors only. For imaging guidelines in metastatic brain cancer, see the appropriate diagnosis-specific section or **Brain Metastases (ONC-31.3)** for imaging guidelines.
- Primary brain tumors presenting only with uncomplicated headache are very uncommon. Most primary brain tumors present with specific CNS symptoms.
- Histologic confirmation is critical. Therapeutic decisions should not be made on radiographic findings alone, except for ANY of the following:
  - Medically fragile individuals for whom attempted biopsy carries excess medical risk, as stated in writing by both the attending physician and surgeon.
  - Brain stem tumors or other sites where the imaging findings are pathognomonic and the risk of permanent neurological damage is excessive with even a limited biopsy attempt.
- For evaluation of known or suspected spinal cord compromise, see: **Spinal/Vertebral Metastases (ONC-31.6)**
- For suspected brain tumors in neurofibromatosis, see: **Screening Imaging in Cancer Predisposition Syndromes (PEDONC-2)** in the Pediatric and Special Populations Oncology Imaging Guidelines
- Rare tumors occurring more commonly in the pediatric population should be imaged according to the imaging guidelines in: **Pediatric Central Nervous System Tumors (PEDONC-4)** in the Pediatric and Special Populations Oncology Imaging Guidelines.

Indication	Medically Necessary Imaging Study
Characterization and follow up of all brain tumors	ANY or ALL of the following: • MRI Brain without and with contrast (CPT® 70553) • CT Head without and with contrast (CPT® 70470) when MRI is contraindicated or not available, or there is skull bone involvement • CT Head (contrast as requested) for preoperative planning when requested by the operating surgeon

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Preoperative planning or to clarify inconclusive findings on MRI or CT	• MRA Head (CPT® 70544) or CTA Head (CPT® 70496)
Within 24 to 72 hours following brain tumor surgery	• MRI Brain without and with contrast (CPT® 70553)
Clinical deterioration or development of new neurological features	• MRI Brain without and with contrast (CPT® 70553) • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) for signs/symptoms of spinal involvement or if spinal involvement is suspected

MR Spectroscopy in Brain Tumors (MRS, CPT® 76390)

- MRS is only medically necessary for use in brain tumors of specified histologies where diagnostic accuracy has been established in peer-reviewed literature.
  - See diagnosis-specific guidelines for MRS indications
- MRS is considered not medically necessary for all other histologies and indications not listed in a diagnosis-specific guideline section.

PET Brain Imaging (CPT® 78608 and CPT® 78609)

- PET Brain Metabolic Imaging (CPT® 78608) is only medically necessary for use in brain tumors of specified histologies where diagnostic accuracy has been established in peer-reviewed literature.
- PET Brain metabolic imaging (CPT® 78608) is considered not medically necessary for all other histologies and indications not listed in a diagnosis-specific guideline section.
- PET Brain perfusion imaging (CPT® 78609) is not medically necessary in the evaluation or management of primary CNS tumors.
- Body PET studies (CPT® 78811, CPT® 78812, and CPT® 78813) and fusion PET/CT studies (CPT® 78814, CPT® 78815, or CPT® 78816) are not medically necessary in the evaluation or management of primary CNS tumors.
- See: **Other Imaging Studies (HD-24)** in the Head Imaging Guidelines for details on other advanced neuro-imaging studies.

Evidence Discussion

Primary central nervous system tumors account for 1.4% of all new cancer diagnoses in the United States and 2.7% of deaths due to cancer. Primary central nervous system tumors develop within any region of the brain. Utilizing the World Health Organization (WHO) classification of tumors, Low grade tumors (WHO I, II) are the most common primary brain tumors (71.7% of all tumors). High grade tumors (WHO II/IV) account for 28.3% of all tumors. Meningioma is the most common low grade tumor accounting for 39.7% of all tumors. Glioblastoma is the most common malignant glioma accounting for 15.4% of all tumors. The most recent classification of these tumors is based on histology and on molecular diagnostics.

The primary imaging modality for the evaluation of primary brain tumors is an MRI Brain and Spine (with and without contrast). The standard MRI protocol minimally includes T1 and T2, fluid-attenuated inversion recovery (FLAIR), gradient-echo/susceptibility, diffusion-weighted imaging, and post contrast T1-weighted images to characterize the tumor. MRI provides much better characterization of intracranial parenchymal tumors in comparison to CT. MRI is more sensitive in detecting lesions in the posterior fossa and in evaluation of leptomeningeal spread of tumor. CT imaging (with and/or without contrast) is valuable in the emergent scenario to assist in initial description of the disease. CT imaging of brain and spine should be used in individuals with a contraindication for use of MRI (those with metallic implants or those who experience claustrophobia). If there is bone involvement, CT imaging may be included with MRI for disease assessment.

Advanced imaging modalities may be included to complement standard imaging to further characterize tumors and assist in treatment decisions. MRI perfusion measures blood flow in the tumor and can be useful in differentiating viable tumor versus radiation necrosis, in determining tumor grade and in determining optimal site for biopsy. MR Spectroscopy involves analysis of the levels of certain chemicals in pre-selected voxels (small regions) on an MRI scan done at the same time. MR spectroscopy may be useful in defining grade of tumor or differentiate viable tumor from radiation necrosis. The use of MR spectroscopy is limited to specific histologies based on peer-reviewed literature. A major limitation of both modalities is the added imaging time. Brain FDG-PET imaging may also be considered to differentiate viable tumor versus radiation necrosis, to determine optimal biopsy site and to determine tumor grade. The use of Brain FDG-PET imaging is limited to specific histologies based on peer-reviewed literature.[1,7-12]

Low Grade Gliomas (ONC-2.2)

ON.CN.0002.2.A
v3.0.2026

- These tumors are defined as having a World Health Organization (WHO) histologic grade of I or II (out of IV), can occur anywhere in the CNS, and includes the following tumors:
  - Pilocytic Astrocytoma
  - Fibrillary (or Diffuse) Astrocytoma
  - Optic Pathway Gliomas
  - Pilomyxoid Astrocytoma
  - Oligodendroglioma
  - Oligoastrocytoma
  - Oligodendrocytoma
  - Subependymal Giant Cell Astrocytoma (SEGA)
  - Ganglioglioma
  - Gangliocytoma
  - Dysembryoplastic infantile astrocytoma (DIA)
  - Dysembryoplastic infantile ganglioglioma (DIG)
  - Dysembryoplastic neuroepithelial tumor (DNT)
  - Tectal plate gliomas
  - Cervicomedullary gliomas
  - Pleomorphic xanthoastrocytoma (PXA)
  - Any other glial tumor with a WHO grade of I or II

Indication	Medically Necessary Imaging Study
Initial Staging	• MRI Brain without and with contrast (CPT® 70553) if not already done • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) ◦ MRI Spine with contrast only (Cervical-CPT® 72142, Thoracic-CPT® 72147, Lumbar-CPT® 72149) if being performed immediately following a contrast-enhanced MRI Brain

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
After initial resection or other treatment (radiation therapy, etc.)	• MRI Brain without and with contrast (CPT® 70553)
For individuals undergoing chemotherapy treatment	• MRI Brain without and with contrast (CPT® 70553) every 2 cycles • Individuals with spinal cord involvement at diagnosis can have MRI without and with contrast of the involved spinal region on the same schedule as MRI brain
ONE of the following: • Determine need for biopsy when transformation to high-grade glioma is suspected based on clinical symptoms or recent MRI findings • Evaluate a brain lesion of indeterminate nature when the study will be used to determine whether biopsy/resection can be safely postponed	ANY of the following: • PET Brain Metabolic Imaging (CPT® 78608) • MRI Perfusion imaging (CPT® 70553)
ONE of the following: • Distinguish low-grade from high-grade gliomas • Evaluate a brain lesion of indeterminate nature when the study will be used to determine whether biopsy/resection can be safely postponed • Distinguish radiation-induced tumor necrosis from progressive disease within 18 months of completing radiotherapy	ANY of the following: • MR Spectroscopy (CPT® 76390) • MRI Perfusion imaging (CPT® 70553)
Suspected intracranial or intraspinal recurrence	• All imaging supported for initial staging

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Surveillance, grade I	• MRI Brain without and with contrast (CPT® 70553) every 3 months for up to 5 years • Individuals with spinal cord involvement at diagnosis: MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) on the same schedule as MRI Brain
Surveillance, grade II (Karnofsky Performance Score ≥60, not poor performance status as below)	• MRI Brain without and with contrast (CPT® 70553) every 3 months for 5 years, then every 6 months thereafter • Individuals with spinal cord involvement at diagnosis: MRI Spine without and with contrast (Cervical- CPT® 72156, Thoracic- CPT® 72157, Lumbar- CPT® 72158) on the same schedule as MRI Brain
Surveillance, grade II and poor performance status (Karnofsky Performance Score <60)	• MRI Brain without and with contrast (CPT® 70553) every 2 months for 3 years, then every 3 months thereafter • Individuals with spinal cord involvement at diagnosis: MRI Spine without and with contrast (Cervical- CPT® 72156, Thoracic- CPT® 72157, Lumbar- CPT® 72158) on the same schedule as MRI Brain

Evidence Discussion

The primary brain tumors classified as low grade gliomas are listed in the guideline. Initial staging in low grade glioma includes both MRI Brain as well as MRI Whole Spine. Whole spine MRI imaging is medically necessary for initial staging as the finding of spinal metastases, leptomeningeal disease will impact prognosis, and treatment approaches. MRI studies should be completed both without and with gadolinium contrast. However, MRI Spine with contrast only can be approved if being performed immediately following a contrast-enhanced MRI Brain for individual-centricity to limit time in the MRI machine if requested since the non-contrast component is less essential for the evaluation of spine. MRI imaging is completed after initial resection or radiation to establish a new baseline for disease monitoring. If intracranial or intraspinal recurrence

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

is suspected or documented, MRI imaging that was completed for initial staging is repeated.

In individuals undergoing active therapy, MRI imaging may be repeated after every 2 cycles of therapy for disease assessment. If there is spine involvement, MRI Spine of the involved spinal region can be included on this same schedule.

Advanced imaging modalities such as MRI perfusion imaging, MR Spectroscopy and/or PET Brain Metabolic Imaging used in conjunction with standard MRI imaging can be performed to characterize non-invasive changes in the tumor not noted on standard MRI or as problem solving tools with inconclusive findings on MRI imaging. Results of these advanced imaging modalities may be the basis to pursue additional treatment and/or surgical intervention; to define transition of the tumor to a higher grade or to distinguish between radiation-induced radiation necrosis and progressive disease within 18 months of completing radiation therapy.

Surveillance imaging is conducted at a frequency and interval based on published standards noted in the NCCN guidelines. Individuals with poor performance status require more frequent imaging than others because of their higher risk for complications or recurrence.[1] More frequent imaging may be done as clinically indicated by the treating physician, in the event of clinical changes such as development of seizures or neurologic deterioration that are suspicious for disease progression.[1,7-12]

High Grade Gliomas (ONC-2.3)

ON.CN.0002.3.A
v3.0.2026

- These tumors are defined as having a WHO histologic grade of III or IV (out of IV can occur anywhere in the CNS (though the majority occur in the brain), and include the following tumors:
  - Anaplastic astrocytoma
  - Glioblastoma multiforme
  - Diffuse intrinsic pontine glioma (DIPG, or “brainstem glioma”)
  - Gliomatosis cerebri
  - Gliosarcoma
  - Anaplastic oligodendroglioma
  - Anaplastic ganglioglioma
  - Anaplastic mixed glioma
  - Anaplastic mixed ganglioneuronal tumors
  - Any other glial tumor with a WHO grade of III or IV

Indication	Medically Necessary Imaging Study
Initial Staging	• MRI Brain without and with contrast (CPT® 70553) if not already done • MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) ◦ MRI Spine with contrast only (Cervical-CPT® 72142, Thoracic-CPT® 72147, Lumbar-CPT® 72149) if being performed immediately following a contrast-enhanced MRI Brain
Immediately following partial or complete resection	• MRI Brain without and with contrast (CPT® 70553)
Immediately following radiation therapy (XRT)	• MRI Brain without and with contrast (CPT® 70553) once within 2 to 8 weeks following completion of treatment, and then go to surveillance imaging

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
For individuals undergoing chemotherapy treatment	• MRI Brain without and with contrast (CPT® 70553) every 2 cycles • Individuals with spinal cord involvement at diagnosis: MRI without and with contrast of the involved spinal region on the same schedule as MRI Brain
ONE of the following: • Distinguish low-grade from high-grade gliomas • Evaluate a brain lesion of indeterminate nature when the study will be used to determine whether biopsy/resection can be safely postponed • Distinguish radiation-induced tumor necrosis from progressive disease within 18 months of completing radiotherapy	ANY of the following: • MR Spectroscopy (CPT® 76390) • MRI Perfusion imaging (CPT® 70553)
ONE of the following: • Distinguish radiation-induced tumor necrosis from progressive disease • Evaluate inconclusive MRI findings when the study will be used to determine need for biopsy or change in therapy, including a change from active therapy to surveillance • Evaluate a brain lesion of indeterminate nature when the study will be used to determine whether biopsy/resection can be safely postponed	ANY of the following: • MRI Perfusion imaging (CPT® 70553) • PET Brain metabolic imaging (CPT® 78608) ◦ PET Brain is not medically necessary in gliomas occurring in the brain stem due to poor uptake and lack of impact on individual outcomes
Suspected intracranial or intraspinal recurrence	• All imaging supported for initial staging

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Surveillance	• MRI Brain without and with contrast (CPT® 70553) every 2 months for 3 years and every 3 months thereafter • Individuals with spinal cord involvement at diagnosis: MRI Spine without and with contrast (Cervical-CPT® 72156, Thoracic-CPT® 72157, Lumbar-CPT® 72158) on the same schedule as MRI Brain

Evidence Discussion

The primary brain tumors classified as high grade gliomas are listed in the guideline. Initial staging in high grade glioma includes both MRI Brain as well as MRI Whole spine. Whole spine MRI imaging is indicated for initial staging as the finding of spinal metastases and leptomeningeal disease will impact prognosis and treatment approaches. MRI studies should be completed both without and with gadolinium contrast. However, MRI Spine with contrast only can be approved if being performed immediately following a contrast-enhanced MRI Brain for individual-centricity to limit time in the MRI machine if requested, since the non-contrast component is less essential for the evaluation of spine. MRI imaging is medically necessary after initial resection or radiation to establish a new baseline for disease monitoring. If intracranial or intraspinal recurrence is suspected or documented, MRI imaging that was completed for initial staging is repeated.

In individuals undergoing active therapy, MRI imaging may be repeated after every 2 cycles of therapy for disease assessment. If there is spine involvement, MRI spine of the involved spinal region can be included on this same schedule.

Advanced imaging modalities such as MRI perfusion imaging, MR Spectroscopy and/or PET Brain Metabolic Imaging used in conjunction with standard MRI imaging can be performed as problem solving tools to characterize non-invasive changes in the tumor noted on standard MRI. Results of these advanced imaging modalities may be the basis to pursue additional treatment and/or surgical intervention; to distinguish low-grade from high-grade gliomas; to distinguish between radiation-induced radiation necrosis and progressive disease within 18 months of completing radiation therapy.

Surveillance imaging is conducted at a frequency and interval based on published standards noted in the NCCN guidelines. More frequent imaging may be done as clinically indicated by the treating physician, in the event of a clinical change such as development of seizures or neurologic deterioration that is suspicious for disease progression.[1,7-12]

CNS Lymphoma (Also Known as Microglioma) (ONC-2.7)

ON.CN.0002.7.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Initial Staging	ALL of the following: • MRI Brain without and with contrast (CPT® 70553) • MRI Cervical Spine without and with contrast (CPT® 72156) • MRI Thoracic Spine without and with contrast (CPT® 72157) • MRI Lumbar Spine without and with contrast (CPT® 72158)
Extra-neural evaluation to confirm CNS primary *Individuals with CNS Lymphoma that is metastatic should be imaged according to: • **Non-Hodgkin Lymphomas (ONC-27)** for individuals age ≥18 years • **Pediatric Aggressive Mature B-Cell Non-Hodgkin Lymphomas (NHL) (PEDONC-5.3)** in the Pediatric Oncology Imaging Guidelines for individuals age ≤17 years	ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • PET/CT (CPT® 78815) for evaluation of inconclusive findings on CT imaging
Treatment Response	• MRI without and with contrast of all positive disease sites every 2 cycles
Suspected intracranial or intraspinal recurrence	• All imaging supported for initial staging

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Surveillance	• For patients with brain involvement only, MRI Brain (CPT® 70553) without and with contrast every 2-3 months for 2 years, then every 6 months to year 5, then annually thereafter • In individuals with a history of leptomeningeal disease, MRI without and with contrast of Brain and Spine (CPT® 70553, 72156, 72157, and/or 72158) every 2-3 months for 2 years, then every 6 months to year 5, then annually thereafter

Evidence Discussion

Primary central nervous system lymphoma is an aggressive non-Hodgkin lymphoma that can occur in any location within the intracranial neuraxis (brain, spine, cranial nerves, and leptomeninges). This malignancy can occur in immunocompromised individuals or immunocompetent individuals and represents approximately 4% of all intracranial malignancies. Individuals may present with focal neurological deficits or nonspecific neurological findings depending on the specific location of tumor involvement.

For initial staging, MRI Brain without and with contrast and whole spine imaging without and with gadolinium contrast are indicated. CNS lymphoma has potential to spread throughout the intracranial neuraxis. For confirmation as a primary central nervous system lymphoma, extra neural evaluation is medically necessary and follows the ONC-27 Non-Hodgkin Lymphoma Guideline. This evaluation includes CT Chest with contrast and CT Abdomen and Pelvis with contrast. FDG PET/CT can be approved if extra-neural CT imaging is inconclusive. Evaluation of treatment response can be assessed after every 2 cycles of treatment with MRI without and with contrast of all positive disease sites. All imaging obtained for initial staging is repeated for suspected disease recurrence to evaluate for metastatic disease. Surveillance imaging includes MRI Brain without and with of all positive disease sites on a schedule outlined in the guideline.[1,12,16]

Meningiomas (Intracranial and Intraspinal) (ONC-2.8)

ON.CN.0002.8.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Inconclusive MRI Brain or CT Head and further imaging is needed to confirm diagnosis	• Dotatate PET/CT Brain (CPT® 78814)
Initial Staging of Intracranial Meningioma	ANY or ALL of the following: • MRI Brain without and with contrast (CPT® 70553) • CT Head (contrast as requested)
Initial staging of Intraspinal Meningioma	ONE of the following: • MRI without and with contrast of appropriate spinal region (Cervical CPT® 72156, Thoracic CPT® 72157, and Lumbar CPT® 72158) OR • CT without and with contrast of the appropriate spinal region (Cervical CPT® 72127, Thoracic CPT® 72130, and Lumbar CPT® 72133)
Treatment Response	• MRI without and with contrast of all positive disease sites every 2 cycles
Suspected recurrence of intracranial or intraspinal disease	• All imaging supported for initial staging
Suspected recurrence with inconclusive findings on MRI	Any ONE of the following studies: • Octreotide SPECT Brain (CPT® 78803) • Octreotide SPECT/CT Brain (CPT® 78830) • Dotatate PET/CT Brain (CPT® 78814)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Surveillance for Grade I (low-grade), or unspecified Grade intracranial meningioma (partially resected and unresected)	• MRI Brain without and with contrast (CPT® 70553) every 3 months in year 1, then every 6 months for 5 years, then annually up to 11 years
Surveillance for Grade II (atypical) intracranial meningioma (partially resected and unresected)	• MRI Brain without and with contrast (CPT® 70553) every 3 months in year 1, then every 6 months for 5 years, then annually indefinitely
Surveillance for Grade I (low-grade), and Grade II (atypical) or unspecified Grade intraspinal meningioma (completely resected, partially resected and unresected)	ONE of the following at 3, 6, and 12 months, and then every 6 months for 5 years, then 1-3 years thereafter as requested: • MRI without and with contrast (CPT® 72156 [Cervical spine], CPT® 72157 [Thoracic spine], CPT® 72158 [Lumbar spine]) of the involved spinal level OR • CT without and with contrast (CPT® 72127 [Cervical spine], CPT® 72130 [Thoracic spine], CPT® 72133 [Lumbar spine]) of the involved spinal level
Surveillance for Grade I (low-grade), completely resected intracranial meningiomas	Annual MRI Brain without and with contrast (CPT® 70553) followed by discontinuation of surveillance if there is no recurrence after 11 years
Surveillance for Grade I (low-grade), completely resected intraspinal meningiomas	MRI of the involved spinal level without and with contrast [ANY of the following: (CPT® 72156 [Cervical spine], CPT® 72157 [Thoracic spine], CPT® 72158 [Lumbar spine])] or CT of the involved spinal level without and with contrast [ANY of the following: (CPT® 72127 [Cervical spine], CPT® 72130 [Thoracic spine], CPT® 72133 [Lumbar spine])] annually followed by discontinuation of surveillance if there is no recurrence after 11 years

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Surveillance for Grade II (atypical), completely resected intracranial meningiomas	MRI Brain without and with contrast (CPT® 70553) annually indefinitely
Surveillance for Grade II (atypical), completely resected intraspinal meningiomas	MRI of the involved spinal level without and with contrast [ANY of the following: (CPT® 72156 [Cervical spine], CPT® 72157 [Thoracic spine], CPT® 72158 [Lumbar spine])] or CT of the involved spinal level without and with contrast [ANY of the following: (CPT® 72127 [Cervical spine], CPT® 72130 [Thoracic spine], CPT® 72133 [Lumbar spine])] annually indefinitely
Surveillance for Grade III (malignant or anaplastic) intracranial meningioma	MRI Brain without and with contrast (CPT® 70553) every 3-4 months for 2 years, and then every 6 months indefinitely
Surveillance for Grade III (malignant or anaplastic) intraspinal meningioma	MRI of the involved spinal level without and with contrast [ANY of the following: (CPT® 72156 [Cervical spine], CPT® 72157 [Thoracic spine], CPT® 72158 [Lumbar spine])] or CT of the involved spinal level without and with contrast [ANY of the following: (CPT® 72127 [Cervical spine], CPT® 72130 [Thoracic spine], CPT® 72133 [Lumbar spine])] every 3-4 months for 2 years, and then every 6 months indefinitely

Evidence Discussion

Meningiomas are the most frequent primary central nervous system tumors, accounting for approximately 34% of all primary brain and spine tumors. Meningiomas are extra-axial, dural-based tumors that are derived from the dura and occur throughout the neuroaxis. Meningiomas are a heterogeneous group of tumors that have been classified in three histologic grades, WHO Grades I (benign), II and III (aggressive). Meningiomas can involve bone resulting in bone overgrowth or infiltration into bony structures. Meningiomas are associated with genetic syndromes and molecular alterations. Approaches for classification are evolving to incorporate histopathologic, genetic and molecular characteristics.

The standard imaging modality is MRI without and with contrast. CT imaging is supported, as there is potential for bone involvement. Meningioma overexpresses somatostatin receptors. PET imaging using various radiolabeled somatostatin receptor

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

ligands (SSAs) such as 68Ga-DOTA-Tyr3-octreotide (DOTATOC), 68Ga-DOTA-d-Phe1-Tyr3-octreotide (DOTATATE), or 68Ga-DOTA-l-Nal3-octreotide (DOTANOC) have been used for the diagnostic evaluation of meningioma. PET imaging with these ligands is supported for restaging to clarify inconclusive findings on MRI imaging.[111] In-octreotide scintigraphy (octreotide) imaging has a similar imaging indication as ^{68}Ga-DOTATATE PET/CT. In surveillance, the schedule for follow-up MRI/CT imaging is based on tumor grade and extent of residual disease.[1,17-19]

Squamous Cell Carcinomas of the Head and Neck – General Considerations (ONC-3.0)

ON.HN.0003.0.A

v3.0.2026

- Individuals with esthesioneuroblastoma should be imaged according to this guideline section.
- Stage III/IV disease encompasses any primary tumor larger than 4cm or documented lymph node positive disease.

Squamous Cell Carcinomas of the Head and Neck – Suspected/Diagnosis (ONC-3.1)

ON.HN.0003.1.A

v3.0.2026

- See: **Neck Masses - Imaging (NECK-5.1)** in the Neck Imaging Guidelines for evaluation of suspected malignancy in the neck.
- PET is medically necessary prior to biopsy in order to determine a more favorable site for biopsy when:
  - a prior biopsy was nondiagnostic or
  - a relatively inaccessible site is contemplated which would require invasive surgical intervention for biopsy attempt

Squamous Cell Carcinomas of the Head and Neck – Initial Work-up/Staging (ONC-3.2)

ON.HN.0003.2.A
v3.0.2026

Indication	Medically Necessary Imaging Study
All Stages of Disease	• CT Neck with contrast (CPT® 70491) **or** MRI Orbits/Face/Neck (OFN) without and with contrast (CPT® 70543) • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250)
For sentinel lymph node evaluation when nodes are not clinically positive	• Lymph system imaging (lymphoscintigraphy, CPT® 78195) ◦ SPECT/CT (CPT® 78830) if requested
Nasal cavity and paranasal sinuses (bony erosion or skull base and intracranial involvement)	ONE of the following: • CT Maxillofacial with contrast (CPT® 70487) • CT Neck with contrast (CPT® 70491) • MRI Orbits/Face/Neck without and with contrast (CPT® 70543)
Nasopharyngeal (NPC) Cancer	• PET/CT (CPT® 78815) • MRI Orbits/Face/Neck without and with contrast (CPT® 70543) is the preferred study ◦ CT Neck (CPT® 70491) **and/or** CT Maxillofacial (CPT® 70487) with contrast if contraindication to MRI • CT Chest with contrast (CPT® 71260)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
For ANY of the following: • Known stage III or IV disease • To determine role for upfront surgery vs chemoradiation in T3-T4 size tumor • Prior to start of primary chemoradiotherapy and have not undergone definitive surgical resection • Inconclusive findings on conventional imaging (CT, MRI) • In order to direct laryngoscopy/exam under anesthesia for biopsy • Pulmonary nodule(s) ≥8mm in size • Cervical lymph node biopsy positive for squamous cell carcinoma and no primary site identified on CT or MRI Neck and Chest • Inconclusive findings suggestive of disease outside the head and neck area	• PET/CT (CPT® 78815)
Signs or symptoms of abdominal metastatic disease including, but not limited to, elevated liver function tests	• CT Abdomen with contrast (CPT® 74160)
Any head and neck cancer with neurological findings or suspicion of skull base invasion	• MRI Brain without and with contrast (CPT® 70553)

Evidence Discussion

Accurate initial staging guides prognosis and management options. CT Neck with contrast or MRI Neck with and without contrast is required for correct tumor, nodal, and metastases (TNM) staging. A contrasted CT of the chest is also medically necessary if requested.

- Classification of tumor staging involves determination of mass size and extent of invasion, if present, of surrounding structures.
- Size and location (including laterality and nodal basin) of pathologic lymph nodes is also required for accurate nodal staging, which will further direct treatment

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

planning to include the extent of potential neck dissection and/or field of radiation. Lymphoscintigraphy is medically necessary, with SPECT if requested, for sentinel node evaluation when nodes are not clinically obviously positive.

- Assessment for potential distant metastases ("M") is based on clinical signs/symptoms and the presence of advanced locoregional primary disease. Discovery of distant metastasis, or a second primary, shifts management to more systemic options. A heavy smoking history also may be a separate indication for advanced imaging of the chest. Up to 7% to 14% of individuals may have a separate lung primary at the time of initial staging of head and neck SCCa. The use of IV contrast improves the detection of mediastinal and hilar adenopathy, and generally, CT Chest with contrast is preferred. Given the rarity of abdominal or pelvic metastatic disease, abdominopelvic imaging is only supported for signs and symptoms of metastatic disease.
  - Nasopharyngeal carcinoma (NPC) has a relatively high rate of distant metastases compared with other head and neck cancers, being found in 5% to 11% of individuals at the time of initial diagnosis. The most common sites of metastasis are bone (20%), lung (13%), and liver (9%).
- FDG-PET/CT Skull Base to Mid-Thigh detects and localizes primary tumor site, and can be helpful in squamous cell carcinoma (SCCa) of the head and neck with unknown primary. It is also equivalent to and possibly superior to contrast-enhanced CT Neck for accurate diagnosis of regional nodal disease. It is helpful in confirming distant metastases as well. The National Comprehensive Cancer Network (NCCN) recommended FDG-PET/CT for initial staging of any NPC, as well as for individuals with locoregionally advanced SCCa (ie, T3-T4 primary or >/= N1 nodal staging).
  - PET/CT alone, however, is not sufficient for initial staging. It does not provide the necessary anatomic detail of the primary tumor's extent for accurate "T" staging, which is required for best selection of local disease management options. Contrast-enhanced CT Neck or MRI Neck are necessary adjuncts.
  - If imaging fails to reveal an obvious primary, PET/CT should be completed before exam under anesthesia, biopsies, and tonsillectomy, to help identify potential primary sites before any intervention occurs.[1,6-12]

Squamous Cell Carcinomas of the Head and Neck – Restaging/Recurrence (ONC-3.3)

ON.HN.0003.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Following primary chemoradiotherapy or radiation therapy or resection or any combination of these modalities	ONE of the following: • CT Neck with contrast (CPT® 70491); **or** • MRI Orbits/Face/Neck without and with contrast (CPT® 70543); **or** • PET/CT (CPT® 78815) no sooner than 12 weeks (3 months) post completion of radiation therapy ◦ If post-treatment PET/CT scan is negative, further surveillance imaging is not medically necessary.
Post-treatment PET is positive for residual disease	ONE of the following: • CT Neck with contrast (CPT® 70491); **or** • MRI Orbits/Face/Neck without and with contrast (CPT® 70543)
Post-treatment PET is equivocal for residual disease	PET/CT (CPT® 78815) 3-6 months from prior post-treatment PET/CT
Induction chemotherapy response	• CT Neck with contrast (CPT® 70491) or MRI Orbits/Face/Neck without and with contrast (CPT® 70543) • PET not medically necessary to assess response to induction chemotherapy
Concern for progression seen on imaging performed at completion of induction chemotherapy	EITHER or ALL of the following: • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) • PET/CT (CPT® 78815)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Measurable or metastatic disease undergoing active treatment	Every 2 cycles (6-8 weeks): • CT Neck with contrast (CPT® 70491) OR • MRI Orbits/ Face/Neck without and with contrast (CPT® 70543) AND • CT with contrast of involved body sites
Suspected local recurrence	• CT Neck with contrast (CPT® 70491) or MRI Orbits/ Face/Neck without and with contrast (CPT® 70543) • CT Chest with contrast (CPT® 71260)
Biopsy proven local recurrence	ONE of the following: • PET/CT (CPT® 78815) **or** • CT Neck with contrast (CPT® 70491) or MRI Orbits/ Face/Neck without and with contrast (CPT® 70543) and CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250)
Inconclusive conventional imaging (CT or MRI)	• PET/CT (CPT® 78815)
If suspected non-response while on treatment	• An additional CT Neck with contrast (CPT 70491) or MRI Orbits/Face/Neck without and with contrast (CPT 70543)
Any of the following: • Known prior thoracic disease • New or worsening pulmonary symptoms • New or worsening chest x-ray findings	• CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion

Follow-up imaging is medically necessary for the evaluation of treatment response. In alignment with the NCCN, a PET/CT is supported following primary chemoradiotherapy in individuals who have not undergone surgical resection of the primary tumor or neck dissection. For individuals receiving induction chemotherapy prior to definitive therapy, a CT or MRI of the primary tumor site to assess response is recommended by NCCN after 2-3 cycles of induction, but a repeat PET/CT is not routinely recommended by NCCN unless there are unclear findings on this CT or MRI. For individuals with metastatic disease on active treatment, cross sectional imaging of involved body areas is supported every 2 cycles. PET/CT is supported for only as a problem-solving tool for inconclusive conventional imaging, as the incidence of false positive findings is high in the setting of ongoing inflammation with known disease.

For individuals treated with primary chemoradiotherapy, a negative PET at the 3-6 month timeframe predicts improved survival at 2 years, with a negative predictive value of 95% to 97%. PET/CT performed earlier than this timeframe is associated with higher false-positive findings and should be avoided. CT or MRI neck may be performed **in lieu of** PET/CT, but PET/CT has excellent sensitivity and specificity in this setting, so these studies are generally not medically necessary **in addition to** a PET/CT as they add additional radiation without a clear impact on management.

For suspected local recurrence, CT or MRI of the primary site (neck/face) is supported, as well as CT of the chest as lung and mediastinal nodes are the most common site of metastatic disease at recurrence, often without pulmonary symptoms. PET/CT has a relatively high false-positive rate due to ongoing inflammatory changes, and thus, these guidelines do not support PET/CT for suspected recurrence until recurrence is proven by biopsy.[1,6-12]

Squamous Cell Carcinomas of the Head and Neck – Surveillance/Follow-up (ONC-3.4)

ON.HN.0003.4.A
v3.0.2026

Indications	Medically Necessary Imaging Study
If post-resection (with or without post-operative radiation therapy) CT or MRI imaging shows residual abnormalities	ONE of the following, once within 6 months of prior imaging: • CT Neck with contrast (CPT® 70491) OR • MRI Orbits/Face/Neck without and with contrast (CPT® 70543)
Individuals treated with definitive radiotherapy	• A second PET/CT (CPT® 78815) is medically necessary 6 months after completion of therapy (i.e., 3 months from the prior PET)
Individuals treated with definitive radiation therapy or combined chemoradiation, and 6-month PET imaging is negative	Further surveillance imaging is not routinely medically necessary
After initial post-treatment study, for ANY of the following: • Nasopharyngeal primary site • Difficult physical exam due to the effects of treatment (e.g., scarring, etc.) or unable to visualize deep-seated primary site	Annually for 3 years: • CT Neck with contrast (CPT® 70491) **or** MRI Orbits/Face/Neck without and with contrast (CPT® 70543)
• CT Chest is not medically necessary for surveillance. Individuals with smoking history may undergo annual low dose CT cancer screening if criteria are met (See: **Lung Cancer Screening (CH-33)** in the Chest Imaging Guidelines)	

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion

Timely detection and accurate assessment of the extent of recurrent disease will direct salvage therapy and improve prognosis. A thorough head and neck clinical examination will typically guide any additional imaging that may be necessary, after post-treatment baseline imaging. There is no controlled prospective data showing a survival benefit for long term surveillance imaging. 3-year disease free survival in individuals undergoing surveillance imaging vs those undergoing clinical surveillance only is not significantly different (41% vs 46%, P=0.91). Given the excellent NPV of PET/CT 3-6 months post therapy, and the fact that median time to recurrence is 6 months, cross sectional imaging is medically necessary once within 6 months of completion of therapy, following the initial post treatment PET/CT. For individuals whose primary tumor site cannot be evaluated with physical exam and for individuals with nasopharyngeal primary tumors, CT Neck or MRI Face/Orbit/Neck are medically necessary annually for 3 years, as 80% to 90% of recurrences occur within 3 years.

The role of annual CT Chest screening for surveillance of lung metastasis is controversial in head and neck cancer, following primary definitive treatment (surgery, XRT, or systemic therapy/XRT). Further study is needed to determine the extent of the positive effect and/or cost-effectiveness of this approach. Individuals with a heavy smoking history may be at increased risk, and may meet criteria for low-dose CT lung cancer screening as defined in CH-33 in the Chest Imaging Guidelines.[1,6-12]

Salivary Gland Cancers – General Considerations (ONC-4.0)

ON.SG.0004.0.A

v3.0.2026

- Salivary gland tumors may originate within the parotid, submandibular, sublingual or minor salivary glands in the mouth.
- Histological subtypes include:
  - mucoepidermoid
  - acinic
  - adenocarcinoma
  - adenoid cystic carcinoma
  - malignant myoepithelial tumors
  - squamous cell carcinoma
  - lymphoma and metastatic squamous carcinoma can occur in the parotid gland
- Over 80% of parotid gland tumors are benign. A bilateral parotid tumor is most likely Warthin's tumor.

Proprietary Information of UnitedHealthcare.

Salivary Gland Cancers – Initial Work-up/ Staging (ONC-4.2)

ON.SG.0004.2.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Biopsy-proven malignancy	ONE of the following: • MRI Orbits/Face/Neck without and with contrast (CPT® 70543) • CT Neck with contrast (CPT® 70491) • CT Neck without contrast (CPT® 70490)
Skull base invasion	• MRI Brain without and with contrast (CPT® 70553)
• Adenoid cystic carcinoma • Lymphadenopathy in the neck • Pulmonary signs or symptoms • Abnormal chest x-ray	• CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250)
Inconclusive findings on conventional imaging	• PET/CT (CPT® 78815)

Evidence Discussion

There are over 40 histologies of salivary gland malignancies, with different patterns of presentation and invasiveness. The choice of MRI vs CT depends on location of tumor, specific symptoms, and individual characteristics. CT may be useful to assess stones and sialadenitis, which may mimic tumor, and is superior for assessing cortical bone erosion. MRI is superior in the assessment of extent of soft tissue disease and perineural invasion. Contrast is recommended in all studies to better outline primary site and to better assess nodal involvement.

In individuals who present with metastatic disease outside the neck, 90% are lung/ chest node metastases. Metastatic disease to lung is most common with adenoid cystic carcinoma and chest imaging is supported in all individuals with this histology. Contrast should be used to allow for assessment of nodal disease in the chest. In other histologies, metastatic disease is less common, and thus chest imaging is only medically necessary in individuals with neck adenopathy, abnormal chest x-ray, or pulmonary signs and symptoms.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Perineural and skull base invasion may occur with salivary gland cancers, particularly with adenoid cystic carcinoma, where perineural spread is seen in 50% to 60% of individuals. When skull base invasion is clinically suspected, an MRI Brain with and without contrast is medically necessary in the interest of individual safety. MRI with and without gadolinium and with fat-saturated, T1 weighted MRI sequences is the most sensitive technique to evaluate for invasion of skull base and perineural invasion.

The role of PET/CT remains controversial in salivary gland cancers. Several studies show no statistically significant different in outcomes with imaging with PET/CT vs conventional imaging. The rate of change in treatment plan based on imaging with PET/CT is widely variable across studies, ranging from 15% to 47%. PET/CT is not adequate to distinguish benign from malignant parotid tumors. Benign tumors such as Warthin's tumor can have FDG uptake, and low-grade malignant tumors may not take up FDG. Healthy salivary glands may also exhibit FDG uptake and obscure tumors. While there is emerging evidence in the use of FDG-PET/CT and PET/MRI to assess for distant disease and perineural spread, it is not considered routine at this time and is not routinely recommended by the NCCN. PET/CT thus remains reserved as a problem-solving tool when conventional imaging is inconclusive.[1-13]

Salivary Gland Cancers – Restaging/ Recurrence (ONC-4.3)

ON.SG.0004.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
After complete surgical resection	One-time imaging to establish baseline within 3-4 months of surgical resection is medically necessary using ONE of the following: • MRI Orbits/Face/Neck without and with contrast (CPT® 70543) • CT Neck with contrast (CPT® 70491) • CT Neck without contrast (CPT® 70490)
Individuals with unresected disease receiving systemic therapy (chemotherapy)	Every 2 cycles: • CT Neck with contrast (CPT® 70491) OR MRI Orbits/Face/Neck without and with contrast (CPT® 70543) • CT with contrast or MRI without and with for any other sites of disease
Recurrence or progression suspected based on new or worsening signs or symptoms	ONE of the following: • CT Neck with contrast (CPT® 70491) • MRI Orbits/Face/Neck without and with contrast (CPT® 70543) In addition, for all individuals: • CT Chest with contrast (CPT® 71260)
Inconclusive findings on conventional imaging	• PET/CT (CPT® 78815)
All other individuals	• No routine advanced imaging

Evidence Discussion

NCCN supported one-time imaging with CT or MRI to establish a new baseline for future comparison.[1] CT or MRI based on initial tumor and individual characteristics

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

is medically necessary every 2 cycles of systemic chemotherapy. If recurrence of progression is clinically suspected at any time, CT neck with contrast or MRI without and with contrast is medically necessary based on prior tumor characteristics and symptoms, per NCCN recommendations and American College of Radiology ACR Appropriateness Criteria®. The incidence of metastatic disease to the chest is higher at recurrence than at initial presentation, with 63% of individuals with metastatic recurrence presenting with metastatic disease to the chest, so CT Chest is medically necessary for suspected recurrence. Contrast should be used to allow better assessment of nodal disease, in addition to parenchymal lesions. PET/CT remains a tool for the clarification of inconclusive findings on conventional imaging. Any CNS symptoms warrant MRI with further guidance in guideline ONC-31.3.[1-13]

Salivary Gland Cancers – Surveillance/ Follow-up (ONC-4.4)

ON.SG.0004.4.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Total surgical resection	• No routine advanced imaging
Unresectable or partially resected disease, including those treated with radiation therapy	• Either CT Neck with contrast (CPT® 70491) or MRI Orbits/Face/Neck without and with contrast (CPT® 70543) once within 6 months of completion of treatment
Adenoid cystic carcinoma	ANY of the following, annually for up to 10 years: • CT Neck with contrast (CPT® 70491) or MRI Orbits/Face/Neck without and with contrast (CPT® 70543) • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250)

Evidence Discussion

The mainstay of surveillance for head and neck cancers including salivary gland carcinoma are frequent history and physical examination. For most histologies, no survival benefit has been documented with imaging surveillance over clinical surveillance. The NCCN notes most recurrences are picked up by individual report of symptoms. For all histologies other than adenoid cystic carcinoma, guidelines support imaging of the primary tumor site once within 6 months from completion of therapy to establish post-treatment baseline, with further imaging guided by signs and symptoms of recurrence. Adenoid cystic carcinoma has the highest incidence of metastatic disease, with over 60 percent of individuals presenting with metastatic disease at recurrence having a history of this histology. They also have the longest risk of recurrence, with a median time to recurrence of 3 years with some recurrences occurring as late as 10 years from diagnosis. For individuals with a history of adenoid cystic carcinoma, CT Neck with contrast or MRI Orbit/Face/Neck as well as CT Chest with or without contrast are medically necessary annually for up to 10 years.[1-13]

Melanoma – Initial Work-up/Staging (ONC-5.2)

ON.SC.0005.2.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Stage 0 or IA (in situ or disease <1mm)	• Routine advanced imaging is not medically necessary
• Stage IB (<0.8mm with ulceration or 0.8-1mm without or with ulceration) • Stage II (lesions >1mm thick, but node negative)	• CT with contrast or MRI without and with contrast of specific areas, only if signs or symptoms indicate need for further evaluation
For sentinel lymph node evaluation in stages IB and II	• Lymph system imaging (lymphoscintigraphy, CPT® 78195) ◦ SPECT/CT (CPT® 78830) if requested
Any of the following: • Stage III (sentinel node positive, palpable regional nodes) • Stage IV (metastatic)	• MRI Brain without and with contrast (CPT® 70553) AND one of the following: • PET/CT (CPT® 78815 or CPT® 78816) OR • CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177)
• Head or neck primary site • Palpable lymphadenopathy in the neck • Mucosal melanoma of the head or neck region	In addition to above initial staging imaging, if PET/CT not performed: • CT Neck with contrast (CPT® 70491)
• Primary site of melanoma is unknown **and** CT Chest, Abdomen, and Pelvis are negative	• PET/CT (CPT® 78815 or CPT® 78816)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion

Formal diagnosis and clinical staging of melanoma needs to take place before any imaging is completed as 84% of individuals present with localized disease, 9% with regional disease, and 4% with distant metastatic disease. Stage 0 (in situ) or 1A does not require routine advanced imaging as the 5 year survival rate is >98% with very little risk for recurrence or metastases. For Stage IB or II disease, sentinel lymph node mapping is medically necessary and depending on results, survival rates range from 50% to 90% - that also incorporates tumor thickness, ulceration and mitotic rate. The yield of imaging in screening individuals with clinical Stage 0-II disease for asymptomatic distant metastatic disease is very low due to low sensitivity and false positive findings. Therefore, the NCCN does not recommend imaging unless needed for surgical planning or to evaluate specific signs or symptoms of disease. Stage III or IV disease can be staged using PET/CT or CT Chest/Abdomen/Pelvis, with PET/CT often preferred due to its superiority over CT in detecting distant metastases. Baseline MRI brain is medically necessary with or without symptoms due to high risk of CNS involvement estimated to be 15.8% at 5 years for Stage III and up to 60% overall in individuals with advanced stage disease. If primary site of melanoma is unknown and CT Chest/Abdomen/Pelvis negative, PET/CT can be performed due to its higher sensitivity and ability to image the extremities.[1,7,17-19]

Click Here to Return to the Main TOC

Melanoma – Restaging/Recurrence (ONC-5.3)

ON.SC.0005.3.A

v3.0.2026

- All recurrences should be confirmed histologically, except when excessive morbidity from a biopsy may occur, such as a biopsy requiring craniotomy.

Indication	Medically Necessary Imaging Study
Individuals receiving chemotherapy, with measurable disease, every 2 cycles (commonly every 6 to 8 weeks)	• CT Chest with contrast (CPT® 71260); **and** CT Abdomen and Pelvis with contrast (CPT® 74177)
All in situ recurrences	• Restaging imaging is not medically necessary after adequate aggressive local therapy (See Surveillance below)
Documented or clinically suspected (see top of page regarding biopsy morbidity) recurrence at: • True scar recurrence (if re-excision suggests more than in situ disease) • In-transit disease • Regional lymph nodes • Metastatic site	• CT Chest with contrast (CPT® 71260); **and** CT Abdomen and Pelvis with contrast (CPT® 74177) In addition, for all individuals: • MRI Brain without and with contrast (CPT® 70553) In addition, for head or neck primary: • CT Neck with contrast (CPT® 70491)
ANY of the following: • Inconclusive findings on conventional imaging • Isolated metastatic site found on conventional imaging	• PET/CT (CPT® 78815 or CPT® 78816)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Brain imaging for: • New discovery of metastatic disease or progression of metastatic disease • Signs or symptoms of CNS disease • If considering Interleukin (IL-2) therapy	• MRI Brain without and with contrast (CPT® 70553)

Evidence Discussion

Individuals receiving chemotherapy with measurable disease can undergo CT Chest/Abdomen/Pelvis every 2 cycles. In situ recurrences do not require restaging imaging due to its high cure rate while recurrence at the primary site, in-transit disease, regional nodes and metastatic site can undergo CT Chest/Abdomen/Pelvis and MRI Brain due to the higher risk of CNS involvement. PET/CT is reserved for inconclusive findings or isolated metastatic site found on CT imaging to guide decisions on local versus systemic therapy. MRI Brain is also medically necessary for newly diagnosed or progressive metastatic disease, signs or symptoms of CNS involvement, or if IL-2 therapy is being considered.[1]

Melanoma – Surveillance/Follow-up (ONC-5.4)

ON.SC.0005.4.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Stage 0, IA, IB and IIA Melanomas	• No routine advanced imaging
Stage IIB, IIC, IIIA and IIIB Melanomas	• CT Chest (CPT® 71260) **and** CT Abdomen and Pelvis (CPT® 74177) with contrast every 6 months for 2 years, then annually for 3 years • For melanoma arising from extremities, advanced imaging of the primary site is not routinely medically necessary for surveillance in asymptomatic individuals.
Stage IIIC and IV Melanomas	• CT Chest (CPT® 71260) **and** CT Abdomen and Pelvis (CPT® 74177) with contrast every 3 months for 2 years, then every 6 months for 3 years • MRI Brain without and with contrast (CPT® 70553) annually for 3 years • For melanoma arising from extremities, advanced imaging of the primary site is not routinely medically necessary for surveillance in asymptomatic individuals.
Mucosal Melanoma of the head or neck region	In addition to above stage-based surveillance imaging, ONCE within 6 months of completing all treatment: • CT Neck with contrast (CPT® 70491) or MRI Orbits/Face/Neck without and with contrast (CPT® 70543) • CT with contrast of any other involved body area
Liver metastases treated with focal therapy	• See: **Liver Metastases (ONC-31.2)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Vulvar or vulvovaginal melanoma stage 0, IA, IB and IIA	Ultrasound of the Abdomen (CPT® 76700 or 76705) and/or Pelvis (CPT® 76856 or 76857)
Vulvar or vulvovaginal melanoma stage IIB or higher	CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) every 3 months for 2 years, and then every 6 months for 3 years

Evidence Discussion

The majority of recurrences, especially in those with early stage disease, are detected clinically by either the individual or during physical exam thus supporting no surveillance imaging in stage 0, 1A, 1B and IIA disease. Furthermore, additional studies have reported low yield, significant false positivity (often associated with increased anxiety and medical costs), and risks of cumulative radiation exposure. Individuals with more advanced disease are more likely to recur, and recur more quickly, with the risk of recurrence reaching low levels after only 2.7 years, thereby supporting stage IIB/IIC as well as stage IIIA/IIIB undergoing CT Chest/Abdomen/Pelvis every 6 months for 2 years then annually for 3 years. Due to the even high risk of early distant recurrence, Stage IIIC/IV should undergo CT Chest/Abdomen/Pelvis every 3 months for 2 years then every 6 months for 3 years as well as MRI brain annually for 3 years. The utility of PET/CT scan in sentinel lymph positive stage III melanoma was minimal with only 2 out of 38 individuals (108 total scans) being true positive with 9 scans showing false positive results thus supporting CT rather than PET/CT imaging in this setting. For melanoma arising from extremities, advanced imaging of the primary site is not medically necessary in asymptomatic individuals. Mucosal melanoma of the head or neck region can also undergo on a one-time basis CT Neck or MRI Orbits/Face/Neck or CT of any other involved body area within 6 months of completing treatment.

The NCCN did not specify the type of imaging required during the workup, response assessment, or surveillance other than listing "cross-sectional with or without brain imaging" thus allowing the provider to determine if CT or PET/CT may be most appropriate. Among the many factors playing a role in this decision are cost, convenience, false positives/false negatives, dye, and radiation exposure.[1,21,22]

Non-Melanoma Skin Cancers – General Considerations (ONC-5.5)

ON.SC.0005.5.A

v3.0.2026

- Advanced imaging is generally not medically necessary for basal cell and squamous cell skin cancers.
- PET/CT scan is not medically necessary for evaluation of non-melanoma skin cancers unless specified within the guidelines below (e.g., Merkel cell carcinoma).
- Merkel cell carcinoma is an unusual skin cancer with neuroendocrine-like histologic features, which has a high propensity (25% to 33%) for regional lymph node spread and occasionally, metastatic spread to lungs.
- Merkel cell carcinoma may present as a primary cancer or as a skin metastasis from a non-cutaneous primary neuroendocrine carcinoma (i.e., small cell lung cancer).

Evidence Discussion

Advanced imaging to include PET/CT is generally not medically necessary for basal cell (BCC) or squamous cell (SCC) skin cancers. The incidence of metastatic BCC was found to be <1% at 14 years of follow-up while metastatic SCC is noted to be rare.[3,15,16]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Non-Melanoma Skin Cancers – Initial Work-up/Staging (ONC-5.6)

ON.SC.0005.6.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Body area with unexplained signs or symptoms	• CT with contrast of that body area
Perineural invasion or local regional extension (i.e., bone; deep soft tissue) involvement	ONE of the following of the primary site: • MRI without contrast **or** without and with contrast • CT (contrast as requested)
Skin lesion may be a dermal metastasis from distant primary	• CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast • PET/CT (CPT® 78815 or CPT® 78816) if conventional imaging (CT or MRI) is unable to identify a primary site
Squamous cell carcinoma head or neck skin with regional lymphadenopathy	• CT Neck (CPT® 70491) and CT Chest (CPT® 71260) with contrast
Merkel Cell carcinoma	• Lymph system imaging (lymphoscintigraphy, CPT® 78195) for sentinel lymph node evaluation ◦ SPECT/CT (CPT® 78830) if requested) • PET/CT (CPT® 78815 or CPT® 78816) OR CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of other involved body area(s)
Signs or symptoms of CNS involvement	• MRI Brain with and without contrast (CPT® 70553)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Evidence Discussion

A body area with unexplained signs or symptoms can undergo imaging with CT with contrast. For SCC, MRI or CT of the primary site with MRI favored if there is perineural or deep soft tissue involvement while CT is preferred for bone disease. If the skin lesion is felt to be a dermal metastasis from a distant primary, CT Chest/Abdomen/Pelvis with contrast is the initial recommended imaging with PET/CT indicated if conventional imaging is unable to identify a primary site and especially if the primary tumor may involve an extremity.[3-5] For Merkel Cell carcinoma, whole-body FDG-PET/CT is preferred.[3]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Non-Melanoma Skin Cancers – Restaging/Recurrence (ONC-5.7)

ON.SC.0005.7.A

v3.0.2026

- All recurrences should be confirmed histologically, except when excessive morbidity from a biopsy may occur, such as a biopsy requiring craniotomy.

Indication	Medically Necessary Imaging Study
Recurrence where planned therapy is more extensive than simple wide local excision	• CT with contrast of the primary and recurrent site(s)
Suspected recurrence of Merkel cell carcinoma	• CT Chest (CPT® 71260) **and** CT Abdomen and Pelvis (CPT® 74177) with contrast • CT with contrast of other symptomatic body area(s)
For the following (for Merkel cell carcinoma): • Inconclusive findings on conventional imaging • If no conventional imaging has been performed, and ONE of the following: ◦ Biopsy-proven recurrence ◦ Suspected in-transit metastatic disease from a primary site in the extremities	• PET/CT (CPT® 78815 or 78816)
Signs or symptoms of CNS involvement	• MRI Brain without and with contrast (CPT® 70553)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion

For recurrences where planned therapy is more extensive than simple wide local excision, CT with contrast of primary site and recurrent site(s) is indicated. Merkel cell carcinoma recurrence can be evaluated with CT Chest/Abdomen/Pelvis plus any other symptomatic areas. PET/CT is medically necessary to evaluate for in-transit metastatic disease if the primary site is in the extremities. MRI Brain is medically necessary for signs or symptoms of CNS involvement.[3-5]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Non-Melanoma Skin Cancers – Surveillance/Follow-up (ONC-5.8)

ON.SC.0005.8.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Merkel cell cancer with any of the following high-risk factors: • Stage II-IV • Individuals assigned male at birth • Immunosuppression • Merkel Cell polyomavirus negative status • Age ≥70 • Non-sentinel lymph node metastases	• CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast every 6 months for 5 years • Add CT Neck with contrast (CPT® 70491) if known prior neck disease or scalp/facial/neck disease
All others	• Routine advanced imaging for surveillance is not medically necessary • Imaging only for signs and symptoms of recurrent disease

Evidence Discussion

In node positive Merkel cell carcinoma, recurrence rates have been found to be up to 33% at 5 years. In addition, individuals assigned male at birth are twice as likely to develop Merkel Cell carcinoma. Also, the likelihood of developing Merkel Cell increases with age. One study showed that 73.6% of Merkel Cell cases are diagnosed at age greater than 70.[24] Additional risk factors for recurrence of Merkel Cell are polyomavirus negative status, non-sentinel lymph node metastases, and immunosuppression. Routine imaging is not medically necessary for SCC or BCC in the absence of signs and symptoms of recurrence.[3-5]

Click Here to Return to the Main TOC

Ocular Melanoma (ONC-5.9)

ON.SC.0005.9.A
v3.0.2026

General Considerations

- Approximately 95% of ocular melanomas arise from the uvea (iris, ciliary body and choroid) and 5% arise from the conjunctiva or orbit.
- Biopsy is usually not necessary for initial diagnosis of uveal melanoma but may be useful in cases when diagnosis is uncertain (e.g., amelanotic tumors, retinal detachment) or for prognostic analysis and risk stratification.
- Treatment is directed to the affected eye with systemic therapy reserved only for known metastatic disease.
- The most common site of metastatic disease is the liver.
- Surveillance of the affected eye is with clinical examination only; advanced imaging is supported for surveillance of systemic metastatic disease based on individual risk factors. See risk categories below for surveillance recommendations.

Ocular Melanoma Risk Categories

Low Risk	Medium Risk	High-Risk
T1	T2 and T3	T4
Class IA	Class IB	Class 2
Spindle cell histology	Mixed Spindle and Epitheloid cells	Epitheloid cell histology
No extraoccular extension	No extraoccular extension	Extraoccular extension present
No ciliary body involvement	No ciliary body involvement	Ciliary body involvement present
Chromosome mutations: • Disomy 3 • EIF1AX mutation • Gain of chromosome 6p	Chromosome mutations: • SF3B1 mutation	Chromosome mutations: • BAP1 mutation • PRAME mutation • Monosomy 3 • Gain of chromosome 8q

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Initial staging of suspected or biopsy-proven uveal melanoma	ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177), OR MRI Abdomen without and with contrast (CPT® 74183) with CT Pelvis with contrast (CPT® 72193), OR MRI Abdomen without and with contrast (CPT® 74183) with MRI Pelvis without and with contrast (CPT® 72197) • MRI Orbits/Face/Neck without and with contrast (CPT® 70543)
Neurological signs/ symptoms	• MRI Brain without and with contrast (CPT® 70553)
Restaging/Suspected Recurrence	ANY or ALL of the following: • MRI Brain without and with contrast (CPT® 70553) • MRI Orbits/Face/Neck without and with contrast (CPT® 70543) • CT Chest with contrast (CPT® 71260) AND one of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) OR • MRI Abdomen without and with contrast (CPT® 74183) with CT Pelvis with contrast (CPT® 72193) OR ◦ Ultrasound Abdomen substituted for MRI Abdomen if requested • MRI Abdomen without and with contrast (CPT® 74183) with MRI Pelvis without and with contrast (CPT® 72197)
Surveillance for Low Risk disease	Annually for 10 years: • CT Chest with contrast (CPT® 71260) • CT Abdomen with contrast (CPT® 74160) or MRI Abdomen without and with contrast (CPT® 74183)
Surveillance for Medium Risk disease	Every 6 months up to year 10: • CT Chest with contrast (CPT® 71260) • CT Abdomen with contrast (CPT® 74160) or MRI Abdomen without and with contrast (CPT® 74183)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Surveillance for High-risk disease	Every 3 months for 5 years, then every 6 months up to year 10: • CT Chest with contrast (CPT® 71260) • CT Abdomen with contrast (CPT® 74160) or MRI Abdomen without and with contrast (CPT® 74183)

Evidence Discussion

Approximately 95% of ocular melanoma occur in the uvea and 5% from the conjunctiva or orbit. Biopsy may not be mandatory for diagnosis but should be performed if diagnosis is uncertain or for prognostic analysis and risk stratification. Less than 3% of cases present with metastatic disease with 5 year risk of metastasis ranging from 3% to 5% in Stage I to 44% or higher in Stage III. The most common site of metastatic disease is the liver (80%) but may also spread to the lungs, bone, skin/soft tissue and lymph nodes. Surveillance of the affected eye is with clinical examination only with advanced imaging supported based on individual risk factors. Initial staging includes MRI orbits/face/neck to determine extraocular extension that impacts treatment planning (radiation therapy versus enucleation). While the risk of baseline metastases may be low, the NCCN favors baseline staging before treatment to include CT Chest/Abdomen/Pelvis in addition to aforementioned MRI. MRI Brain is medically necessary with any neurologic signs or symptoms. Restaging/recurrence with same imaging as initial staging as well as including MRI Brain. Surveillance: Local recurrence is rare (<10%) and the development of metastatic disease is much more common (up to 70% up to 20 years after initial diagnosis) hence the following recommendations for surveillance that does not include local imaging unless clinically indicated. For low risk disease, CT Chest with CT or MRI of the abdomen annually for 10 years. For medium risk disease, same as low risk but every 6 months for a total of 10 years. For high-risk disease, every 3 months for 5 years, then annually for a total of 10 years. The NCCN recognized the optimal surveillance strategy is an issue of debate due to overall low yield of testing and the risk of cumulative radiation exposure.[2, 25]

Thyroid Cancer – General Considerations (ONC-6.0)

ON.TC.0006.0.A

v3.0.2026

- Individuals of all ages with thyroid cancer are imaged according to this guideline.
- Whole-Body Thyroid Nuclear scan (also known as whole-body radioiodine scan) is coded with CPT® 78018. If CPT® 78018 is obtained and found to be positive, CPT® 78020 is medically necessary as an add-on test to evaluate the degree of iodine uptake.
- Single photon emission computed tomography (SPECT) imaging – Radiopharmaceutical Localization of Tumor SPECT (CPT® 78803 or CPT® 78831) or SPECT/CT Hybrid study (CPT® 78830 or CPT® 78832) may complement planar and pinhole imaging and can be approved as an add-on wherever radioiodine (RAI) scans are indicated.
- Whole-Body Thyroid Nuclear scan (also known as whole-body RAI scan) is the imaging modality of choice for differentiated thyroid cancers, as these are usually not well visualized on FDG-PET/CT scans. Individuals who have RAI-diagnostic scan negative and PET-positive disease will generally not respond to RAI treatment, whereas individuals who have PET-negative and RAI-diagnostic scan negative disease may still be candidates for empiric RAI treatment.
- Radioiodine (RAI) refractory disease is defined as: (i) the malignant/metastatic tissue does not ever concentrate RAI (no uptake outside the thyroid bed at the first therapeutic WBS), (ii)the tumor tissue loses the ability to concentrate RAI after previous evidence of RAI-avid disease (in the absence of stable iodine contamination), (iii) RAI is concentrated in some lesions but not in others, and (iv) metastatic disease progresses despite significant concentration of RAI.

Thyroid Cancer – Initial Work-up/Staging (ONC-6.2)

ON.TC.0006.2.A
v3.0.2026

Follicular, Papillary, and Hürthle Cell (Oncocytic) Carcinomas	Medically Necessary Imaging Study
ONE of the following: • Locally advanced disease or fixation suggested by clinical exam and/or ultrasound • Substernal or bulky disease • Disease precluding full ultrasound examination • Vocal cord paresis	ONE of the following: • MRI Neck without contrast (CPT® 70540) • MRI Neck without and with contrast (CPT® 70543) • CT Neck with contrast (CPT® 70491) if contrast study is necessary for complete pre-operative assessment and use of IV contrast will not delay post-operative use of RAI therapy.
• Extent of thyroid remnant cannot be accurately ascertained from the surgical report, neck ultrasound, or cross-sectional imaging • Unresectable residual disease • To assess for iodine-avid metastatic disease • When the results may alter the decision to treat • Prior to administration of RAI therapy	• Whole-Body Thyroid Nuclear scan (CPT® 78018) ◦ CPT® 78020 as an add-on test to evaluate the degree of iodine uptake AND/OR • SPECT (CPT® 78803, or CPT® 78831), OR SPECT/CT Hybrid study (CPT® 78830, or CPT® 78832)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Follicular, Papillary, and Hürthle Cell (Oncocytic) Carcinomas	Medically Necessary Imaging Study
Skeletal pain	• Bone scan (CPT® 78306) See also: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes • Whole-Body Thyroid Nuclear scan (CPT® 78018) ◦ CPT® 78020 as an add-on test to evaluate the degree of iodine uptake AND/OR • SPECT (CPT® 78803 or CPT® 78831), OR SPECT/CT Hybrid study (CPT® 78830, or CPT® 78832)
Suspicious findings on chest x-ray, US, or substernal extension of mass	• CT Chest without contrast (CPT® 71250)
All other individuals	• Routine preoperative advanced imaging is not medically necessary

Medullary Thyroid Carcinomas	Medically Necessary Imaging Study
ANY of the following: • Elevated CEA levels • Calcitonin level >300pg/mL • Positive lymph nodes	ANY or ALL of the following: • CT Neck with contrast (CPT® 70491) • CT Chest with contrast (CPT® 71260) • CT Abdomen with contrast (CPT® 74160) **or** CT Abdomen without and with contrast (CPT® 74170) • MRI Abdomen without and with contrast (CPT® 74183) • Bone scan (CPT® 78306) see also: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Medullary Thyroid Carcinomas	Medically Necessary Imaging Study
Skeletal pain	• Bone scan (CPT® 78306) see also: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes
Inconclusive findings on conventional imaging	• ^{68}Gallium-labeled PET/CT (CPT® 78815)

Anaplastic/Poorly Differentiated Thyroid Carcinomas	Medically Necessary Imaging Study
All	ANY or ALL of the following: • CT Neck with contrast (CPT® 70491) or MRI Orbit, Face, Neck without and with contrast (CPT® 70543) • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • FDG PET/CT (CPT® 78815) • CT Head with contrast (CPT® 70460)
Skeletal pain	• Bone scan (CPT® 78306) see also: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes

Evidence Discussion

For follicular, papillary and Hurthle cell carcinomas, focused imaging of the neck using contrast enhanced CT or MRI is medically necessary to assess extent of local disease and guide pre-surgical planning. CT Chest with contrast may be medically necessary based on these results to include substernal extension of the thyroid mass. There are no established guidelines regarding the minimum gap between contrast enhanced CT with iodinated contrast agents and iodine-131/123 for whole body scintigraphy (WBS) in the treatment of residual disease and distant metastases, with majority recommendation of a gap of 4 weeks and 2 months. In the post-thyroidectomy setting, WBS is medically necessary to assess for either extent of thyroid remnant, when results may alter the decision to treat and prior to administration of radioactive iodine (RAI) therapy. In the presence of skeletal pain, whole body bone scan or WBS is medically necessary to assess for osseous metastases. Medullary thyroid carcinoma is frequently aggressive

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

with 48% of individuals having localized disease, 35% with tumors extending beyond the thyroid into surrounding tissues or regional nodes and 13% with distant metastases typically to the lung, liver or bones. Due to these concerns, more extensive staging is medically necessary that includes contrast enhanced CT of neck, chest and abdomen as well as bone scan if there are elevated CEA levels, calcitonin level >300 pg/nL or positive lymph nodes. Skeletal pain can be imaged with bone scan. Gallium-68 labelled dotatate PET/CT or if not available Indium-111-pentetreotide (Octreoscan) is useful due to high expression of somatostatin receptors in MTC and is medically necessary if conventional imaging is inconclusive due to its high sensitivity compared to other imaging modalities especially if calcitonin levels are >500. Anaplastic thyroid carcinoma is the most aggressive variant of thyroid cancer with distant metastases in over 50% of cases at presentation most commonly involving the lung, bone and brain with 5 year survival <10%. Complete staging with CT Neck, Chest, Abdomen and Pelvis is medically necessary in conjunction with FDG PET/CT as the diagnostic contrasted CTs may better elucidate vascular and airway involvement. MRI of the brain is also medically necessary.[4,6,9,10,13]

Thyroid Cancer – Restaging/Recurrence (ONC-6.3)

ON.TC.0006.3.A
v3.0.2026

Follicular, Papillary, and Hürthle Cell (Oncocytic) Carcinomas	Medically Necessary Imaging Study
Post-thyroidectomy, if gross residual disease	ONE of the following: • MRI Neck without contrast (CPT® 70540) • MRI Neck without and with contrast (CPT® 70543) • CT Neck with contrast (CPT® 70491)
Within 2 weeks (ideally 7 to 10 days) following the administration of Radioactive Iodine therapy	• Whole-body thyroid nuclear scan (CPT® 78018) • The following may be approved as an add-on test: ◦ CPT® 78020 to evaluate the degree of iodine uptake ◦ SPECT (CPT® 78803, or CPT® 78831), or SPECT/CT Hybrid study (CPT® 78830, or CPT® 78832)
ANY of the following: • Recurrence documented by biopsy • Increasing thyroglobulin level without Thyrogen® stimulation • Thyroglobulin level >2 ng/mL or higher than previous after Thyrogen® stimulation • Anti-thyroglobulin antibody present • Evidence of residual thyroid tissue on ultrasound or physical exam after thyroidectomy or ablation	ALL of the following: • CT Neck with contrast (CPT® 70491) or MRI Neck without and with contrast (CPT® 70543) • CT Chest with contrast (CPT® 71260) • CT with contrast of any symptomatic body area • Whole-body Thyroid Nuclear Scan (CPT® 78018) ◦ As an add-on test: ▪ CPT® 78020 to evaluate the degree of iodine uptake ▪ SPECT (CPT® 78803 or CPT® 78831), or SPECT/CT Hybrid study (CPT® 78830, or CPT® 78832)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Follicular, Papillary, and Hürthle Cell (Oncocytic) Carcinomas	Medically Necessary Imaging Study
ANY of the following: • Rising thyroglobulin level with negative CT scans AND radioiodine scan • Inconclusive findings on conventional imaging (CT scans and radioiodine scan) • Known radioiodine-refractory disease and CT scans are negative or inconclusive	• FDG PET/CT (CPT® 78815)
Measurable metastatic disease on systemic therapy (no more often than every 2 cycles)	• CT Chest with contrast (CPT® 71260) • CT with contrast of affected or symptomatic body area

Medullary Thyroid Carcinoma	Medically Necessary Imaging Study
ANY of the following: • Elevated CEA levels • Calcitonin level ≥150 pg/mL • Signs or symptoms of recurrence	ANY or ALL of the following: • CT Neck with contrast (CPT® 70491) or MRI Neck without and with contrast (CPT® 70543) • CT Chest with contrast (CPT® 71260) • CT Abdomen either with (CPT® 74160) or without and with contrast (CPT® 74170) • Bone scan (CPT® 78306) See also: **Nuclear Medicine (NM) Imaging (ONC-1.3)** in Oncology
Inconclusive conventional imaging with calcitonin ≥150 pg per mL	• ^{68}Gallium-labeled DOTATATE PET/CT (CPT® 78815)
Calcitonin level >500	ONE of the following: • MRI Abdomen without and with contrast (CPT® 74183) • Whole-body MRI (CPT® 76498)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Anaplastic/Poorly Differentiated Thyroid Carcinoma	Medically Necessary Imaging Study
Measurable metastatic disease on systemic treatment	Any of the following every 2 cycles (usually every 6-8 weeks): • CT Neck with contrast (CPT® 70491) • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT of any other involved/symptomatic sites
Signs or symptoms of recurrence	ONE of the following combinations, not both: • CT Neck with contrast (CPT® 70491), CT Chest with contrast (CPT® 71260), CT Abdomen and Pelvis with contrast (CPT® 74177) **OR** • FDG PET/CT (CPT® 78815) In addition to one of the above studies: • MRI Brain without and with contrast (CPT® 70553)

Evidence Discussion

For Follicular, Papillary and Hurthle Cell carcinomas, CT or MRI neck can be performed if gross residual disease is found in the neck post-thyroidectomy. RAI therapy is administered after thyroidectomy for several reasons to include remnant ablation, treat presumed foci of neoplastic cells and/or treat persistent or recurrent disease. Within 2 weeks of treatment, WBS is medically necessary to stage the disease and document the I-131 avidity of any structural lesion. Follow-up is usually a combination of exam, laboratories (thyroglobulin and anti-thyroglobulin antibody levels) and ultrasound. If there is concern for recurrence, CT of the neck/chest as well as any symptomatic body area along with WBS should be performed to complete restaging. In the setting of rising thyroglobulin level with negative conventional imaging, inconclusive conventional imaging or known RAI-refractory disease with negative/inconclusive CT scans, FDG PET/CT can be performed due to its high sensitivity (94%) and specificity (80% to 84%) compared to conventional imaging. FDG uptake is associated with a worse prognosis and refractoriness to RAI therapy. Initial imaging for MTC recurrence based on elevated CEA levels, calcitonin level >150 pg/mL or signs/symptoms of recurrence should

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

undergo CT or MRI Neck, CT Chest and Abdomen, and bone scan. If this imaging is inconclusive and calcitonin is >150, Gallium-68 labeled dotatate PET/CT or if not available Indium-111-pentetreotide (Octreoscan) is medically necessary as outlined in the initial work-up/staging section. In individuals with very high calcitonin levels, whole-body MRI or MRI liver are useful for imaging evaluation to evaluate for metastases.[1] Initial imaging for ATC recurrence includes either CT Neck, Chest, Abdomen and Pelvis or FDG PET/CT as well as MRI Brain due to its aggressive and widespread behavior. For individuals on systemic therapy, CT of neck/chest/abdomen/pelvis with any additional involved/symptomatic sites can be done every 2 cycles.[11]

Thyroid Cancer – Surveillance/Follow-up (ONC-6.4)

ON.TC.0006.4.A
v3.0.2026

Follicular, Papillary, and Hürthle Cell (Oncocytic) Carcinomas	Medically Necessary Imaging Study
Individuals being monitored on active surveillance	• Neck ultrasound (CPT® 76536) every 6 months for 2 years, and then annually thereafter
All other individuals post-treatment	• Neck ultrasound (CPT® 76536) once at 6-12 months post-treatment, and then annually thereafter
For individuals with ANY of the following: • Node positive disease • RAI-avid metastases	• Whole-body Thyroid Nuclear Scan annually (CPT® 78018) ◦ CPT® 78020 as an add-on test to evaluate the degree of iodine uptake AND/OR • SPECT (CPT® 78803, or CPT® 78831), OR SPECT/CT Hybrid study (CPT® 78830, or CPT® 78832)

Medullary Carcinomas	Medically Necessary Imaging Study
All individuals	• CEA and calcitonin are required for monitoring medullary carcinomas • Routine surveillance imaging is not medically necessary

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Anaplastic/Poorly Differentiated Thyroid Carcinomas	Medically Necessary Imaging Study
All individuals	Every 3 months for 2 years: • CT Neck with contrast (CPT® 70491) • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Brain without and with contrast (CPT® 70553)

Evidence Discussion

For follicular, papillary and Hurthle cell carcinomas, all individuals are monitored with ultrasound either every 6 months for 2 years then annually (active surveillance) or once at 6-12 months then annually (post-treatment). For node positive disease or RAI-avid metastases, WBS annually. MTC is monitored with CEA and calcitonin levels with no routine imaging medically necessary. ATC requires close monitoring with CT Neck/ Chest/Abdomen/Pelvis and MRI Brain every 3 months for 2 years as the vast majority of relapses occur within this timeframe.[1,9]

Small Cell Lung Cancer – General Considerations (ONC-7.0)

ON.SL.0007.0.A

v3.0.2026

- Combined histologies of small and non-small cell are considered small cell lung cancer. Use this guideline for imaging recommendations for small and large cell high-grade (poorly differentiated) neuroendocrine tumors of the lung.
- Imaging is presently guided by traditional staging of limited or extensive disease.
  - Extensive stage is either metastatic disease or an extent which cannot be encompassed by a single radiotherapy portal.
  - Limited staging is confined to one side of the chest.
- Individuals treated curatively for SCLC are at increased risk for developing a second lung cancer. If new lung nodule is seen on imaging without any evidence of other systemic disease, follow **Lung Metastases (ONC-31.1)** for work-up of nodule.
- For carcinoid (low-grade neuroendocrine tumors) of the lung, see: **Neuroendocrine Cancers and Adrenal Tumors (ONC-15)**.

Health Equity Considerations

The National Cancer Institute (NCI) has estimated 226,650 new cases of lung cancer and 124,730 estimated deaths from lung cancer (Non-Small Cell Lung Cancer and Small Cell Lung Cancer combined) in the United States in 2025. Lung cancer is the leading cause of cancer-related mortality in the United States. These poor survival factors are related to tobacco use, late-stage diagnosis, and underutilization of new and effective treatments. While smoking is the most important risk factor, other risk factors include secondhand smoke, occupational exposure, such as to asbestos, radiation exposure, such as from radiation therapy or radon exposure, air pollution, family history, and HIV infection.[12]

The U.S. Preventive Services Task Force (USPSTF) recommends annual screening for lung cancer with low-dose computed tomography (LDCT) in adults aged 55 to 80 years who have a 30 pack-year smoking history and currently smoke or who have quit within the past 15 years.[13] According to the American Lung Association, individuals of color are less likely to be diagnosed early, less likely to receive surgical treatment, and more likely to receive no treatment.[14] Populations with a low socioeconomic status also have barriers to lung cancer screening due to lack of or poor insurance and under-resourced clinics. In addition, after diagnosis, they have lower odds of receiving treatments, including surgery, chemotherapy, and immunotherapy, leading to poorer survival.[15] Multiple strategies are needed to address disparities, including enhancing

Small Cell Lung Cancer – Suspected/ Diagnosis (ONC-7.1)

ON.SL.0007.1.A
v3.0.2026

Indication	Medically Necessary Imaging Study
• Abnormal chest x-ray or clinical suspicion remains high despite a normal chest x-ray in symptomatic individual	• CT Chest without contrast (CPT® 71250) **or** • CT Chest with contrast (CPT® 71260)
• Pulmonary nodule <8mm in size noted on CT Chest	• See: **Incidental Pulmonary Nodules Detected on CT Images (CH-16.2)** in the Chest Imaging Guidelines
• Pulmonary nodule 8mm (0.8cm) to 30mm (3cm) seen on dedicated chest imaging (See **Solitary Pulmonary Nodule - Imaging (CH-16.1)**)	• PET/CT (CPT® 78815) • PET is Positive: Qualifies as initial staging PET/CT
• Pulmonary mass 31mm (3.1cm) or greater seen on CT or MRI	• PET/CT (CPT® 78815) prior to biopsy if ONE or MORE of the following applies: ◦ Definitive treatment with resection or radiation will be utilized instead of biopsy if PET confirms limited disease ◦ Multiple possible biopsy options are present within the chest and PET findings will be used to determine the most favorable biopsy site • Biopsy is indicated prior to PET imaging for all other indications in pulmonary masses ≥31mm (3.1cm) in size
• Mediastinal/Hilar Mass	See: **Lymphadenopathy (CH-2)** in the Chest Imaging Guidelines
• Paraneoplastic syndrome suspected	See: **Paraneoplastic Syndromes (ONC-30.3)**

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Evidence Discussion

For individuals with suspected lung cancer and an abnormal chest x-ray or a high suspicion for lung cancer with symptoms of lung cancer, a CT Chest is medically necessary, with or without contrast. If a PET/CT is performed in the workup of a pulmonary nodule and is positive, it qualifies as the initial staging PET. The radiotracer supported for PET/CT for lung cancer is 18-FDG.[6,9] While some small cell lung cancer (SCLC) has a neuroendocrine component, the sensitivity, specificity and predictive value of dotatate PET/CT are uncertain at this time and dotatate PET is not supported.[6,9] Lesions 31mm or greater are considered masses rather than nodules, and should be biopsied rather than re-imaged with PET/CT.[5]

Small Cell Lung Cancer – Initial Work-up/ Staging (ONC-7.2)

ON.SL.0007.2.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Initial staging	ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Brain without and with contrast (CPT® 70553) • Bone scan (CPT® 78306), if PET/CT not being done or not available (See also: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes)
• To confirm the extent of disease when initial CT Chest/Abdomen/Pelvis and MRI Brain indicate limited stage disease (confined to one side of the chest) • To evaluate inconclusive findings on conventional imaging	• PET/CT (CPT® 78815)
• Inconclusive bone findings on PET/CT or bone scan	• MRI without and with contrast of the involved body site

Evidence Discussion

SCLC has widespread distant metastatic potential, with 2/3 of individuals having metastatic disease at diagnosis and 10% to 15% including central nervous system disease.[6,9] Diagnostic contrasted CTs of chest, abdomen and pelvis as well as MRI Brain with and without contrast are medically necessary.[1] If PET has been completed in the pulmonary nodule workup, a repeat PET/CT is generally not medically necessary. If a PET/CT was done prior to diagnosis and conventional imaging clearly shows extensive stage disease, a PET/CT does not change management. However, if a PET/CT was not done prior to diagnosis, a PET/CT is medically necessary to confirm limited stage disease prior to treatment, as FDG PET/CT changes stage versus conventional

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

imaging in up to 25% of individuals.[6,9] Bony metastatic disease is not unusual in SCLC; thus, evaluation for bony metastatic disease is medically necessary.[1,6]

Small Cell Lung Cancer – Restaging/ Recurrence (ONC-7.3)

ON.SL.0007.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Treatment response in individuals treated with sequential chemotherapy-radiation or chemotherapy alone* *For individuals receiving systemic therapy and concurrent radiation therapy, response assessment is recommended only after completion of initial therapy (see box below).	After every 2 cycles, ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Brain without and with contrast (CPT® 70553) for measurable brain metastases being treated with systemic therapy • Bone scan (CPT® 78306) (See also: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes) • PET is not medically necessary for evaluation of treatment response in SCLC but can be considered on a case-by-case basis.
Following completion of planned treatment: • Chemoradiation • Adjuvant chemotherapy • Radiation	ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Brain without and with contrast (CPT® 70553) for measurable brain metastases being treated with systemic therapy • Bone scan (CPT® 78306) (See also: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3**) for additional bone scan codes)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Restaging (suspected recurrence)	ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Brain without and with contrast (CPT® 70553) • Bone scan (CPT® 78306) (See: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes) • PET is not medically necessary for evaluation of recurrent SCLC but can be considered on a case-by-case basis.
For response assessment following primary treatment	• MRI Brain without and with contrast (CPT® 70553)

Evidence Discussion

Conventional imaging with contrasted CT Chest, Abdomen and Pelvis is medically necessary every 2 cycles of chemotherapy and at the end of chemoradiation. MRI Brain with and without contrast is medically necessary when there is measurable CNS disease being treated with systemic therapy. If prophylactic cranial irradiation (PCI) is planned, an MRI brain is medically necessary at end of initial treatment as some individuals will harbor asymptomatic brain metastases and will require different management, and PCI would expose the individual to radiation doses and neurotoxicity without benefit.[1,7] CT Chest, Abdomen and Pelvis as well as MRI Brain and bone scan are medically necessary if recurrence is suspected. Further literature is emerging to determine the role of FDG PET-CT for treatment response and suspected recurrence; these guidelines do not routinely support PET/CT for treatment response or suspected recurrence of SCLC, but provide flexibility on a case by case basis, particularly for individuals with bony metastatic disease.[1,8,9]

Small Cell Lung Cancer – Surveillance/ Follow-up (ONC-7.4)

ON.PC.0007.4.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Limited stage SCLC	Every 3 months for two years, every 6 months during year three, and then annually: • CT Chest without (CPT® 71250) or CT Chest with (CPT® 71260) contrast • CT Abdomen and Pelvis with contrast (CPT® 74177)
Extensive stage SCLC	Every 2 months for one year, every 3 months for two years, every 6 months for two years, and then annually: • CT Chest without (CPT® 71250) or CT Chest with (CPT® 71260) contrast • CT Abdomen and Pelvis with contrast (CPT® 74177)
Screening for brain metastases, regardless of PCI status	• MRI Brain without and with contrast (CPT® 70553) every 3 months for 1 year and then every 6 months thereafter
Surveillance of known and/or treated brain metastases	• See: **Brain Metastases (ONC-31.3)**
New lung nodule(s)	• See: **Lung Metastases (ONC-31.1)**

Evidence Discussion

Surveillance with CT contrasted chest, abdomen and pelvis is medically necessary. MRI Chest is less sensitive than CT Chest and usually not medically necessary as a substitution for lung cancer. Follow up is supported more frequently in the first two years post-treatment, as that is when recurrence is most common.[1,6,9] The surveillance timeframe is determined by the initial extent of disease. For those with limited stage disease, these guidelines support the above CT imaging every 3 months for 2 years, every 6 months during year 3, and then annually. For those with extensive stage disease, imaging with above CTs is supported every 2 months for 1 year, every 3 months for two years, every 6 months for 2 years, then annually. This is in alignment with the follow up visit timeframe recommended by NCCN. Up to 30% of

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

individuals develop metastatic disease to the brain. Screening for brain metastases is medically necessary to allow early treatment of brain metastases prior to potentially impairing neurologic symptoms. MRI is preferred over CT for its increased sensitivity and specificity, at an interval of every 3 months for 1 year then every 6 months indefinitely.[1,7,9] PET/CT is not medically necessary for surveillance due to excessive radiation exposure, false positive incidental findings, and financial toxicity.

Non-Small Cell Lung Cancer – General Considerations (ONC-8.0)

ON.NL.0008.0.A
v3.0.2026

- Non-small cell lung cancer includes adenocarcinoma, squamous cell carcinoma, adenosquamous and large cell tumors.
- See: **Bronchopulmonary or Thymic Carcinoid – Initial Staging (ONC-15.6)** for evaluation of low-grade neuroendocrine tumors (carcinoid) of the lung.
- See: **Small Cell Lung Cancer (ONC-7)** for evaluation of high-grade small cell and large cell neuroendocrine tumors of the lung.
- PET/CT is medically necessary to confirm solitary focus of extra-pulmonary metastatic disease (i.e., brain or adrenal) if the individual is being considered for an aggressive treatment for oligometastatic disease.

Health Equity Considerations

The National Cancer Institute (NCI) has estimated 226,650 new cases of lung cancer and 124,730 estimated deaths from lung cancer (Non-Small Cell Lung Cancer and Small Cell Lung Cancer combined) in the United States in 2025. Lung cancer is the leading cause of cancer-related mortality in the United States. These poor survival factors are related to tobacco use, late-stage diagnosis, and underutilization of new and effective treatments. While smoking is the most important risk factor, other risk factors include secondhand smoke, occupational exposure, such as to asbestos, radiation exposure, such as from radiation therapy or radon exposure, air pollution, family history, and HIV infection.[18]

The U.S. Preventive Services Task Force (USPSTF) recommends annual screening for lung cancer with low-dose computed tomography (LDCT) in adults aged 55 to 80 years who have a 30 pack-year smoking history and currently smoke or who have quit within the past 15 years.[17] According to the American Lung Association, individuals of color are less likely to be diagnosed early, less likely to receive surgical treatment, and more likely to receive no treatment.[19] Populations with a low socioeconomic status also have barriers to lung cancer screening due to lack of or poor insurance and under-resourced clinics. In addition, after diagnosis, they have lower odds of receiving treatments, including surgery, chemotherapy, and immunotherapy, leading to poorer survival.[20] Multiple strategies are needed to address disparities, including enhancing access to care and implementing tools such as real-time tracking, individual navigation, and mobile screening units.[21]

Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Paraneoplastic syndrome suspected	See: **Paraneoplastic Syndromes (ONC-30.3)**

Evidence Discussion

For individuals with suspected lung cancer and an abnormal chest x-ray or a high suspicion for lung cancer with symptoms of lung cancer, a CT Chest is medically necessary, with or without contrast. If a PET/CT is performed in the workup of a pulmonary nodule and is positive, it qualifies as the initial staging PET. The radiotracer supported for PET/CT for lung cancer is 18-FDG.[3,14] Lesions 31mm or greater are considered masses rather than nodules.[3] There is no clear evidence for PET/CT over biopsy in this case. Generally, masses should be biopsied rather than re-imaged. PET/CT is medically necessary if definitive treatment with resection or radiation will be utilized instead of biopsy (if PET confirms limited disease), or if multiple biopsy sites are present within the chest and PET findings will be used to determine the most favorable biopsy site. This maximizes safety when making decisions regarding invasive procedures.

Non-Small Cell Lung Cancer – Initial Work-up/Staging (ONC-8.3)

ON.NL.0008.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
All individuals	ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen with contrast (CPT® 74160) ◦ CT Abdomen can be omitted if CT Chest report clearly documents upper abdomen through level of adrenals • PET/CT (CPT® 78815) (if not already completed prior to histological diagnosis) • Bone scan (CPT® 78306, if PET/CT not being done) See also: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes
Stage IB-IV disease	• MRI Brain without and with contrast (CPT® 70553) ◦ If MRI Brain is contraindicated or not available, CT Head with contrast (CPT® 70460) or CT Head without and with contrast (CPT® 70470)
Superior sulcus (Pancoast) tumor suspected	ANY or ALL of the following: • MRI Chest without and with contrast (CPT® 71552) • MRI Cervical Spine without and with contrast (CPT® 72156) • MRI Thoracic Spine without and with contrast (CPT® 72157)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Evidence Discussion

CT Chest and upper abdomen to the level of the adrenals is medically necessary for initial staging, as liver and adrenal metastatic disease are common in NSCLC. Pelvic disease is rare and imaging of the pelvis without pelvic symptoms is not recommended by NCCN.[1] FDG PET-CT is supported by NCCN in all individuals.[1]

Over 10% of individuals with stage III or IV disease present with metastatic disease to the brain, and 4% to 5% of individuals with stage II disease. MRI Brain with and without contrast has a higher detection rate for metastatic disease to the brain than CT, and is medically necessary in all individuals with stage II-IV disease.[1] For individuals with stage IB disease, MRI Brain with and without contrast is optional in this setting but can be considered to prevent under-staging and under-treatment, since a small number of individuals with apparent stage I disease and no CNS symptoms will have occult brain lesions and will require additional therapies.[1,14]

For individuals with superior sulcus (Pancoast) tumor, MRI Chest and MRI Cervical and Thoracic Spine with and without contrast have higher specificity for chest wall invasion, neurologic involvement, and fibrosis than CT alone, and are medically necessary in addition to the imaging stated above.[1,13]

Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Newly identified lung nodule(s)	• See: **Lung Metastases (ONC-31.1)** for new nodule evaluation
ANY of the following: • Suspected/biopsy proven recurrence localized to the chest cavity • Inconclusive findings on conventional imaging • To differentiate tumor from radiation scar/fibrosis • Stage IV with oligometastatic disease on conventional imaging and individual is a candidate for aggressive surgical resection or other localized treatment of metastases with a curative intent	• PET/CT (CPT® 78815)
ANY of the following: • Following a demonstrated adequate response to neoadjuvant therapy if intracranial disease will preclude surgery • Documented recurrence/progression • New or worsening neurological signs or symptoms	• MRI Brain without and with contrast (CPT® 70553)

Evidence Discussion

In alignment with NCCN, CT Chest and Abdomen with contrast are medically necessary every two cycles, with pelvic imaging only for a history of pelvic disease or new pelvic symptoms. These are also medically necessary at any time for clinically suspected recurrence. MRI Brain with and without contrast is medically necessary every 2 cycles for individuals with known brain metastases being treated with systemic therapy, or at any time for individuals with new neurologic symptoms or documented systemic progression.[1] An additional CT Chest is medically necessary if requested after neoadjuvant therapy to evaluate for resectability, in the interest of safe resection. CT is also medically necessary post-operatively to assess baseline prior to starting adjuvant therapy, in alignment with NCCN.[1]

Non-Small Cell Lung Cancer – Surveillance/Follow-up (ONC-8.5)

ON.NL.0008.5.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Stage I-II (treatment including surgery and/ or chemotherapy, but no radiation)	• CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) every 6 months for 3 years and then annually
Stage I-II treated with radiation therapy Stage III-IV (metastatic sites treated with definitive intent)	• CT Chest with contrast (CPT® 71260) **or** CT Chest without contrast (CPT® 71250) every 3-6 months for 3 years, every 6 months for 2 years and then annually
New lung nodule	• See: **Lung Metastases (ONC-31.1)**

Evidence Discussion

CT Chest with or without contrast is recommended by national guidelines every 6 months for 3 years and then annually for individuals with stage I or II disease. To prevent under-treatment, individuals treated with radiation who have residual abnormalities on imaging may undergo more frequent imaging every 3-6 months for the first year then every 6 months for 2 years, then annually thereafter. Individuals with stage II disease or definitively treated metastatic disease are at higher risk for relapse particularly in the first 2 years, and NCCN recommended CT Chest every 3-6 months for 3 years, every 6 months for 2 years, then annually. Asymptomatic abdominal and pelvic imaging exposes to radiation with low-yield for metastatic disease detection and is not medically necessary. FDG-PET is not medically necessary for surveillance due to excessive false positive rates, radiation exposure, and increased risk of unnecessary procedures for incidental false positive findings. MRI Brain for asymptomatic surveillance is low yield in asymptomatic NSCLC surveillance and is not routinely recommended.[1,2]

Esophageal and GE Junction Cancer – General Considerations (ONC-9.0)

ON.EJ.0009.0.A

v3.0.2026

- Imaging for esophageal cancer is determined by cell type and in which third of the esophagus it occurs.
- Cancers of the upper and middle third are usually squamous cell and are highly associated with tobacco and alcohol abuse.
- Cancers of the gastroesophageal (GE) junction are treated as lower third cancers. Lower third cancers are usually adenocarcinomas; 62% of these arise in the setting of Barrett's esophagus, a condition associated with high body mass index (BMI).

Esophageal and GE Junction Cancer – Initial Work-up/Staging (ONC-9.2)

ON.EJ.0009.2.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Biopsy proven	• CT Chest (CPT® 71260) and CT Abdomen (CPT® 74160) with contrast ◦ CT Abdomen and Pelvis with contrast (CPT® 74177) instead of CT Abdomen if there are pelvic signs or symptoms
In addition to the above, for any of the following: • Upper 1/3 of esophagus • Neck mass	• CT Neck with contrast (CPT® 70491)
If no evidence of metastatic disease on conventional imaging	• PET/CT (CPT® 78815)

Evidence Discussion

- Upon initial diagnosis of cancer, CT Chest/Abdomen is medically necessary with the addition of pelvis if there are signs/symptoms of disease. NCCN stated that "CT can be used to determine the location of the primary tumor and its proximity to other structures".[1]
- Cancers diagnosed in the upper 1/3 of the esophagus should also obtain CT of the neck due to concern for nodal spread.
- If CT imaging does not show evidence of metastatic disease, PET/CT is medically necessary to assess for occult metastases to help finalize treatment options (curative versus palliative). PET/CT is not sensitive for locoregional nodal assessment as often these nodes are obscured by metabolic activity in the primary tumor but is more sensitive than CT for detecting distant metastases.
- NCCN also stated that PET/CT has "limited ability to ability to differentiate between cT1, cT2, and cT3 tumors. Therefore, CT should be performed as part of initial workup (as well as pelvic CT scan with contrast if clinically indicated) while FDG-PET/CT should be reserved for individuals with no evidence of M1 disease".[1]

Esophageal and GE Junction Cancer – Restaging/Recurrence (ONC-9.3)

ON.EJ.0009.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
• After completion of primary therapy (to include chemotherapy and/or chemoradiotherapy), prior to surgery • After completion of chemoradiation therapy with definitive intent (i.e., no metastatic disease and no anticipated resection surgery)	Any ONE of the following, not both: • PET/CT (CPT® 78815) no sooner than 5 weeks post completion of radiation therapy OR • CT Chest (CPT® 71260) and CT Abdomen (CPT® 74160) with contrast ◦ CT Abdomen and Pelvis with contrast (CPT® 74177) instead of CT Abdomen if there are pelvic signs or symptoms or known pelvic disease
Post-surgical resection	• See: **Surveillance/Follow-up (ONC-9.4)**
Monitoring response to chemotherapy for stage IV/ metastatic disease	Every 2 cycles of treatment (~every 6-8 weeks): • CT Abdomen with contrast (CPT® 74160) • CT Chest with contrast (CPT® 71260)
• If conventional imaging is inconclusive **or** • Salvage surgical candidate with recurrence and no metastatic disease documented by conventional imaging	• PET/CT (CPT® 78815)
For ANY of the following: • Signs or symptoms of recurrence • Biopsy proven on follow-up endoscopy • Recurrence suggested by other imaging (i.e., chest x-ray or barium swallow)	• CT Chest (CPT® 71260) and CT Abdomen (CPT® 74160) with contrast

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
If previously involved or new signs or symptoms	• CT Pelvis with contrast (CPT® 72193) and/or CT Neck with contrast (CPT® 70491)

Evidence Discussion

- Primary treatment typically involves chemoradiotherapy alone, surgery alone, or both.
- After primary chemoradiation has been completed and prior to surgery, one of the following is medically necessary: CT Chest/Abdomen or PET/CT, with the latter ideally no sooner than 5 weeks after completion of radiation to minimize risk of false positives.
- Post-surgical resection is handled as disease surveillance.
- For Stage IV disease on chemotherapy, CT Chest/Abdomen is medically necessary every 2 cycles.
- If conventional imaging is inconclusive or the member is a candidate for salvage surgery upon recurrence with no evidence of metastatic disease, PET/CT is medically necessary.
- CT Chest/Abdomen is medically necessary for signs/symptoms of recurrence, biopsy proven recurrence on follow-up endoscopy, and recurrence suggested by other imaging.
- CT imaging of any appropriate area (e.g., neck, pelvis) is medically necessary if new signs/symptoms or known previous involvement.[1]

Esophageal and GE Junction Cancer – Surveillance/Follow-up (ONC-9.4)

ON.EJ.0009.4.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Stage 0-IA (Tis, T1a) disease	• No routine advanced imaging
Stage IB (T1b)-III disease	• CT Chest (CPT® 71260) and CT Abdomen (CPT® 74160) with contrast every 6 months for 2 years and then annually for 3 more years
Stage IV disease	• See: **General Guidelines (ONC-1.0)**

Evidence Discussion

- Stage 0-IA (Tis, T1a): No routine advanced imaging is medically necessary. Fully treated Tis and T1aN0 disease have prognoses that approximate a non-cancer cohort.[1]
- Stage IB (T1b)-III: CT Chest/Abdomen with contrast every 6 months for 2 years and then annually for 3 more years. T1b does not perform as well as fully treated Tis and T1aN0 disease, thus supporting current recommendations.[1]
- Stage IV: CT Chest/Abdomen (additional sites as clinically indicated) every 3 months while on maintenance therapy or every 3 months up to 5 years if being monitored off therapy.[1]

Malignant Pleural Mesothelioma – Initial Work-up/Staging (ONC-10.2)

ON.OT.0010.2.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Cytologically or pathologically proven	• CT Chest (CPT® 71260) **and** CT Abdomen (CPT® 74160) with contrast ◦ CT Abdomen and Pelvis with contrast (CPT® 74177)instead of CT Abdomen if there are pelvic signs or symptoms or prior pelvic involvement
For EITHER of the following: • No evidence of distant metastatic disease on CT imaging • Inconclusive conventional imaging	• PET/CT (CPT® 78815)
Suspicion of possible chest wall, spinal, diaphragmatic, or vascular involvement based on CT imaging	• MRI Chest without and with contrast (CPT® 71552)

Evidence Discussion

Contrasted CT Chest and CT Abdomen are medically necessary for initial staging once mesothelioma is proven with lung fluid cytology or tissue biopsy. Contrast allows better evaluation of nodal disease in addition to parenchymal disease and offers improved characterization of direct extrapulmonary tumor invasion. MRI is inferior for parenchymal lung imaging; thus, CT is essential. Anatomic soft tissue detail, differentiation from progressive benign fibrosis, and brachiocephalic vascular involvement may be better demonstrated on MRI without and with contrast, so this study is medically necessary for suspected chest wall, spine, diaphragm, or vascular involvement. The most common site of metastatic disease outside the chest is the liver, so CT Abdomen is an important

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

part of the initial workup. However, pelvic disease is rare and pelvic CT exposes to additional radiation and is low yield in individuals without pelvic signs and symptoms. Pelvis may be added to contrasted CT in individuals with signs and symptoms of pelvic involvement, including direct abdominoperitoneal invasion. National Cancer Database review of over 40,000 individuals treated between 2004 and 2020 reveals that 50% of individuals are metastatic upon presentation.[17] Signs and symptoms of metastatic disease in body areas not addressed in ONC-10 may be imaged according to their respective sections in ONC-31, for which separate evidence summaries are provided.

PET/CT is not first line imaging for mesothelioma as it is inadequate for differentiating benign vs malignant changes in exposure-related progressive massive pulmonary fibrosis, but of which take up FDG in unpredictable fashions. Understaging of the primary site is common with PET/CT alone. Conventional imaging is essential. However, PET/CT is medically necessary to confirm the absence of metastatic disease on conventional imaging (negative or inconclusive) prior to resection, as up to 29% of individuals initially identified as operable may be reclassified as inoperable due to identification of distant metastatic disease on PET/CT during pre-operative evaluation.[1]

Click Here to Return to the Main TOC

Malignant Pleural Mesothelioma – Restaging (ONC-10.3)

ON.OT.0010.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Signs or symptoms of recurrence	• CT Chest (CPT® 71260) **and** CT Abdomen (CPT® 74160) with contrast ◦ CT Abdomen and Pelvis with contrast (CPT® 74177) instead of CT Abdomen if there are pelvic signs or symptoms or prior pelvic involvement
Treatment with chemotherapy	Every 2 cycles: • CT Chest (CPT® 71260) **and** CT Abdomen (CPT® 74160) with contrast ◦ CT Abdomen and Pelvis with contrast (CPT® 74177) instead of CT Abdomen if there are pelvic signs or symptoms or prior pelvic involvement
Following induction chemotherapy prior to surgical resection	• CT Chest (CPT® 71260) **and** CT Abdomen (CPT® 74160) with contrast ◦ CT Abdomen and Pelvis with contrast (CPT® 74177) instead of CT Abdomen if there are pelvic signs or symptoms or prior pelvic involvement • PET/CT (CPT® 78815) if no evidence of distant metastatic disease
Inconclusive CT Chest	• MRI Chest without and with contrast (CPT® 71552)

Evidence Discussion

For individuals on chemotherapy, contrasted CT of chest and abdomen are medically necessary every 2 cycles. Pelvic imaging may be added for signs and symptoms of peritoneal/pelvic disease or known pelvic/peritoneal disease as noted in the initial staging section. The same logic applies to any individuals with signs and symptoms of recurrence. For individuals receiving induction chemotherapy, CT Chest and Abdomen (with pelvis if previously reviewed indications are present) are medically necessary at end of induction. Response is categorized by validated mRECIST criteria on CT. If there

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

is no metastatic disease, this may again be confirmed with PET/CT prior to attempted resection, ensuring the individual is not subjected to futile invasive surgery when RT or further systemic therapy may be more appropriate. If CT Chest is inconclusive, MRI Chest without and with contrast is medically necessary. MRI Chest may differentiate between treatment-related changes (fibrosis) and persistent mesothelioma, which is not well-differentiated on PET/CT as both may have unpredictable FDG uptake.[1,10-13,17]

Malignant Pleural Mesothelioma – Surveillance (ONC-10.4)

ON.OT.0010.4.A
v3.0.2026

Indication	Medically Necessary Imaging Study
All	• CT Chest with contrast (CPT® 71260) and previously involved regions every 3 months for 2 years, then annually thereafter

Evidence Discussion

There is no clear consensus for surveillance imaging for malignant pleural mesothelioma, and NCCN offered no guidance on this topic. The European Society of Medical Oncology (ESMO) advised CT for surveillance without a specific timeframe.[13] Given the known value of CT in assessing primary mesothelioma and abdomino/peritoneal metastatic disease, these guidelines support CT for surveillance. The timeframe is based on National Cancer Database survival statistics for malignant pleural mesothelioma.[2] In review of 40,000+ individuals treated between 2004 and 2020, individuals undergoing surgery had a median survival time for 19.8 months, compared with 7.9 months in those who had not undergone surgery. The 2-year survival for those who underwent surgery was 44%, with 18% 2-year survival in unresectable disease. 5-year survival is 5% in unresected disease, and 16% in those who underwent surgery. These guidelines support CT Chest and Abdomen with contrast every 3 months for the first 2 years, then annually. As noted in the restaging section, CT imaging is always medically necessary for new signs and symptoms.[1]

Indication	Medically Necessary Imaging Study
Encapsulated or invasive limited disease	• CT Chest with contrast (CPT® 71260)
Extensive mediastinal involvement on CT Chest	• CT Abdomen with contrast (CPT® 74160) • CT Neck with contrast (CPT® 70491)
Inconclusive finding on CT	ONE of the following: • PET/CT (CPT® 78815) • MRI Chest without and with contrast (CPT® 71552)
Preoperative planning	• MRI Chest without and with contrast (CPT® 71552)
Thymic Carcinomas	• Image according to **Non-Small Cell Lung Cancer - Initial Work-up/Staging (ONC-8.3)**

Evidence Discussion

Thymomas and thymic carcinomas originate in the thymus and are epithelial tumors. Thymomas are rare tumors (though most common primary tumor of anterior mediastinum) that typically spread locally with 5-year survival rates of 90% while thymic carcinomas are very rare, more invasive, and often present with metastases with 5-year survival rates of 55%.[3] Initial imaging for thymoma includes CT Chest with contrast that usually shows a well-defined rounded or oval mass without adenopathy. If there is extensive mediastinal involvement, CT Neck/Abdomen with contrast can be performed. If CT imaging is inconclusive, PET/CT or MRI Chest with and without contrast is medically necessary, with MRI preferred in thymic carcinoma.[14,15] For preoperative planning, MRI Chest is also medically necessary.

Thymoma and Thymic Carcinoma – Restaging (ONC-10.7)

ON.OT.0010.7.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Adjuvant therapy following surgical resection	• Follow surveillance imaging
Following induction chemotherapy prior to surgical resection, if no evidence of metastatic disease	ONE of the following: • PET/CT (CPT® 78815) • CT Chest with contrast (CPT® 71260) • MRI Chest without and with contrast (CPT® 71552)
For suspected recurrence	• CT Chest with contrast (CPT® 71260)
Recurrence with extensive mediastinal involvement on CT Chest	• CT Abdomen with contrast (CPT® 74160) • CT Neck with contrast (CPT® 70491)
Inconclusive finding on CT	ONE of the following: • PET/CT (CPT® 78815) • MRI Chest without and with contrast (CPT® 71552)
Metastatic disease on chemotherapy	• CT Neck (CPT® 70491), CT Chest (CPT® 71260), and CT Abdomen (CPT® 74160) with contrast, every 2 cycles of therapy
Thymic carcinomas	• See: **Non-Small Cell Lung Cancer Restaging/ Recurrence (ONC-8.4)**

Evidence Discussion

If induction chemotherapy is given, PET/CT can be obtained prior to surgical resection as studies have shown a correlation of radiographic response to pathologic response to help guide resectability.[16] Chest imaging with CT or MRI are also accepted imaging choices for this purpose. For recurrence, CT Chest with CT Neck/Abdomen is medically

necessary. PET/CT or MRI Chest is medically necessary if CT Chest is inconclusive. For individuals on chemotherapy for metastatic disease, CT Neck/Chest/Abdomen with contrast can be given every 2 cycles.[3]

Thymoma and Thymic Carcinoma – Surveillance (ONC-10.8)

ON.OT.0010.8.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Thymoma, R0 resection	• CT Chest with contrast (CPT® 71260) and previously involved regions every 6 months for 2 years, then annually until year 10
Thymoma, R1 or R2 resection	• CT Chest with contrast (CPT® 71260) and previously involved regions every 6 months for 2 years, then annually until year 10
Thymic carcinoma, R0 resection	• CT Chest with contrast (CPT® 71260) every 6 months for 2 years and then annually until year 5
Thymic carcinoma, R1 or R2 resection	• CT Chest with contrast (CPT® 71260) and previously involved regions every 3 months for 2 years, then annually until year 5

Evidence Discussion

Thymoma surveillance is stratified into resection categories by NCCN. Thymoma surveillance should be with CT Chest with contrast and any previously involved areas for 10 years due to the risk of late recurrence.[3] For thymic carcinoma, like thymoma, management depends on the extent of resection. NCCN stated "patients who have an R0 resection have a 5-year survival of approximately 60%".[3] Thymic carcinoma surveillance recommendations from NCCN are based on consensus as there is a paucity of published studies specifically addressing surveillance imaging of thymic carcinoma. The recommendation includes imaging for 5 years.[3]

Breast Cancer – General Considerations (ONC-11.0)

ON.BC.0011.0.A

v3.0.2026

- This guideline applies to invasive carcinoma and ductal carcinoma in situ histologies of breast cancer.
- Advanced imaging to evaluate for distant metastases is not medically necessary for asymptomatic individuals with invasive carcinoma or ductal carcinoma in situ (DCIS).
- High-risk lesions, such as LCIS, ADH, and ALH are discussed in **Breast MRI Indications (BR-5.1)**.
- Bone scan has a high concordance rate with PET for detecting bone metastases.
- Scintimammography and Breast Specific Gamma Imaging (BSGI) are considered experimental, investigational, or unproven.
- For malignant phyllodes tumors of the breast, see **Sarcomas - Bone, Soft Tissue, and GIST (ONC-12)**

Health Equity Considerations

Breast cancer is the second most deadly form of cancer among women in the United States and the most common form of cancer apart from skin cancer.[37] In the United States, the lifetime risk of dying from breast cancer is 1 in 39.[38] While the mortality rate from breast cancer has decreased in some populations, the overall rates of cancer among Black and Hispanic populations has continued to grow. Breast cancer rates are higher in White women, yet Black women are more likely to die from breast cancer. Medical advances have improved early detection, diagnosis, and screening, yet Black women still face significant barriers to receiving adequate treatment. In recent years, the 5-year survival rate has been 81% for Black women compared to 92% for White women, highlighting a persistent disparity in outcomes.[37]

Breast cancer rates, survival, mortality rates, and risk factors vary not only by race and ethnicity, by also by socioeconomic status. Women with low incomes are significantly less likely to undergo breast cancer screening, more likely to be diagnosed at a later stage, and often receive inadequate or inequitable treatment, which are factors that contribute to higher mortality rates.[37] In studies of individuals on Surveillance, Epidemiology, and End Results (SEER) Medicare, those who were non-White, located in rural areas, were of older age, and had comorbidities were all less likely to receive appropriate radiation after a breast cancer diagnosis.[39]

To eliminate breast cancer health disparities, the lack of sufficient and diverse data will need to be addressed, as well as building a better understanding of cancer etiology and appropriate treatments for different populations.[40]

Breast Cancer – Initial Work-up/Staging (ONC-11.2)

ON.BC.0011.2.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Newly diagnosed breast cancer or ductal carcinoma in situ	• Diagnostic bilateral mammogram and/or Ultrasound Breast (CPT® 76641 or CPT® 76642) and/or Ultrasound Axilla (CPT® 76882) are imaging modalities of choice (See **Breast Ultrasound (BR-1.1))** • MRI Breast bilateral without and with contrast (CPT® 77049)
ANY of the following: • Atypical ductal hyperplasia (ADH) • Atypical lobular hyperplasia (ALH) • Lobular carcinoma in situ (LCIS)	See: **Breast MRI Indications (BR-5.1)**
ANY of the following: • Ductal carcinoma in situ • Stage I-III	• For sentinel lymph node evaluation: Lymph system imaging (lymphoscintigraphy, CPT® 78195) ◦ SPECT/CT (CPT® 78830) if requested
Stages I, II, and operable stage III (N1 disease)	• Routine systemic imaging is not medically necessary for initial staging of non-metastatic breast cancer in the absence of signs or symptoms

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
ANY of the following: • Diagnosis of breast cancer with suspected or proven metastatic disease or biopsy-proven distant metastases/ Stage IV disease (not locally advanced disease with three or less positive axillary nodes) • Signs or symptoms of systemic disease • Elevated liver function tests or tumor markers • Inflammatory breast cancer (stage T4d) • 4 or more axillary lymph nodes positive for cancer involvement (i.e., N2 disease, including Stage III N2)	ANY or ALL of the following: • CT Chest (CPT® 71260) **and** CT Abdomen and Pelvis (CPT® 74177) with contrast • Bone scan (CPT® 78306) (if PET/CT is not being performed) See: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes
ANY of the following: • Stage III N2 disease or higher • T4 disease • Inflammatory breast cancer (stage T4d) • Inconclusive CT and/or bone scan	In addition to the above: • FDG PET/CT (CPT® 78815)
Bone pain	• Bone scan (CPT® 78306) (see: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)**) for additional bone scan codes • PET/CT (CPT® 78815) with Sodium Fluoride radiotracer if CT, MRI, Bone scan and FDG PET/ CT scan are inconclusive for bone metastases • See: **Bone (Non-Vertebral) Metastases (ONC-31.5)** • See: **Spinal/Vertebral Metastases (ONC-31.6)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion

Evaluation of disease in the breast/axilla with breast MRI:

National Comprehensive Cancer Network (NCCN) guidelines stated that breast MRI "may be used for staging evaluation to define extent of cancer or presence of multifocal or multicentric cancer in the ipsilateral breast, or to screen the contralateral breast at the time of initial diagnosis".[1] Disagreement continues to exist as to whether the benefit of breast MRI in initial staging outweighs the drawbacks. Detractors cite evidence of increased time-to-surgery, high false-positive rates among the reasons to avoid universal usage of breast MRI in initial staging.[12,32] The American Society of Breast Surgeons Consensus (ASBrS) statement recommended against the use of routine MRI in the preoperative workup of individuals with breast cancer.[11] MRI may be helpful in elucidating whether disease exists in the intervening breast tissue thereby aiding in tumor size estimation and the decision to opt for mastectomy vs. lumpectomy. NCCN cautioned that "surgical decisions should not be based solely on MRI findings".[1] Breast MRI has been shown to find occult primary cancers in roughly two thirds of individuals who present with positive axillary lymph nodes, allowing for definitive surgical management.[31] NCCN stated that breast MRI "may be helpful for evaluation before and after preoperative systemic therapy to define extent of disease, response to treatment, and potential for breast-conservation therapy".[1] Breast MRI has also been shown to more accurately predict tumor size in individuals with invasive lobular carcinoma than conventional imaging.[36] While data are limited on the use of breast MRI in the setting of Paget's disease of the breast, one study found that for individuals with a histologic diagnosis of Paget's disease and a negative mammogram, MRI was able to detect occult cancer in 4/8 (50%) individuals.[34] NCCN guidelines noted that there is considerable controversy in the use of MRI based on breast density.[1] They noted that MRI advocates argue that it has a high sensitivity to find occult disease in "dense breasts where mammographically occult disease is more likely to elude preoperative detection"; however, MRI detractors note the high percentage of false- positive findings, resulting in further workup, overestimation of extent of disease, and increased frequency of mastectomy. Given the recommendation by NCCN that breast MRI may be useful for specific circumstances in initial staging, these guidelines allow for the approval of breast MRI in initial staging to empower individuals and providers to discuss the risks and benefits of this modality and move forward with the most advantageous choice for the individual's specific circumstances.

Lymphatic mapping with lymphoscintigraphy and/or SPECT/CT:

Sentinel node biopsy is important in the staging of individuals with breast cancer. However, lymphoscintigraphy has limited utility in this setting.[21] In individuals with recurrent disease who have had previous axillary surgery, lymphoscintigraphy with SPECT/CT may be helpful in delineating alternate drainage pathways.[20] In individuals who have had a positive axillary node prior to neoadjuvant chemotherapy, some authors

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

have also found the technique to be helpful in identifying the previously positive clipped node, which may not be subsequently identified as a sentinel node.[23]

Systemic staging with CT Chest, Abdomen, Pelvis, and bone scan vs. PET/CT:

The NCCN guidelines stated to "consider additional imaging studies only in the presence of signs and symptoms of metastatic disease and for patients who are clinically high risk".[1] This is in keeping with the ACR Appropriateness Criteria which stated that systemic staging is "usually not appropriate" for all newly diagnosed clinical Stage I-IIA (early stage) breast cancer.[37] Over a third of individuals with inflammatory breast cancer will have distant metastatic disease at presentation and NCCN recommended staging studies in these individuals.[1,33]

NCCN guidelines recommended CT scan for the work up for distant metastatic disease.[1] NCCN also stated that the "routine use of FDG PET/CT is not recommended in the staging of clinical stage I, II, or operable III (T3,N1) breast cancer.[1] However, NCCN indicated that PET/CT may be performed at the same time as diagnostic CT and can be helpful as a problem-solving tool when conventional imaging is suspicious or inconclusive. It is also noted to be "helpful in identifying unsuspected regional nodal disease and/or distant metastases when used in addition to standard staging studies".[1] Bone imaging is not recommended if FDG PET/CT is already going to be performed.[1] Given the above, these guidelines allow for the selected use of concomitant PET/CT for initial staging in specific clinical circumstances.

Breast Cancer – Restaging/Recurrence (ONC-11.3)

ON.BC.0011.3.A
v3.0.2026

- For imaging related to breast reconstruction, see: **Breast Reconstruction (BR-3.1)** in the Breast Imaging Guidelines

Indication	Medically Necessary Imaging Study
ANY of the following: • End of planned neoadjuvant chemotherapy to determine resectability • Biopsy proven local recurrence • Suspicion of recurrence with inconclusive mammogram and/or ultrasound (BIRADS 0) • Mammogram and/or ultrasound conflicts with physical exam	• MRI Breast Bilateral without and with contrast (CPT® 77049)
After neoadjuvant chemotherapy, if sentinel lymph node evaluation is planned	• Lymph system imaging (lymphoscintigraphy, CPT® 78195) ◦ SPECT/CT (CPT® 78830) if requested
ANY of the following: • Assessing for residual disease after surgery • Assessing response to neoadjuvant chemotherapy • After lumpectomy or mastectomy, prior to adjuvant therapy	• Neither PET nor CT are medically necessary for systemic restaging after neoadjuvant chemotherapy or after surgery • If surgery upstages individual to Stage III N2 disease or higher and has not had prior staging, refer to **Breast Cancer – Initial Work-up/Staging (ONC-11.2)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
• Treatment response in individuals with metastatic disease and measurable disease on imaging ◦ For individuals receiving chemotherapy, imaging is medically necessary after every 2 cycles ◦ For individuals receiving hormonal or endocrine therapy, imaging is medically necessary every 3 months	• CT Chest with contrast (CPT® 71260); and CT Abdomen and Pelvis with contrast (CPT® 74177) • Bone scan (CPT® 78306) (see also: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes) In addition to the above options, for individuals receiving systemic treatment for brain metastases: • MRI Brain without and with contrast (CPT® 70553)
ANY of the following: • Elevated LFTs • Elevated tumor markers • Signs or symptoms of recurrence • Biopsy proven recurrence	Any or all of the following: • CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast • Bone scan (CPT® 78306) (See also: **Nuclear Medicine (NM) Imaging in Oncology) (ONC-1.3)** for additional bone scan codes) For individuals with prior history of brain metastases or current signs or symptoms of brain metastases: • MRI Brain without and with contrast (CPT® 70553)
• Inconclusive CT, MRI, and/or bone scan • Treatment response assessment for bone-only metastases (excluding brain metastases) and a prior bone scan has not been performed for serial comparison	• ^{18}F-FDG PET/CT (CPT® 78815)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Individuals with known or suspected bone metastases AND inconclusive bone findings on ALL of the following: • CT, MRI, bone scan, and FDG PET/CT scan	• ^{18}F Sodium Fluoride PET/CT (CPT® 78815)
To determine the ER-status of suspected/known metastatic recurrence noted on CT/bone scan **and** any one of the following: • Biopsy of metastatic site is non-diagnostic/inconclusive • Biopsy of metastatic site is risky & cannot be performed (metastatic sites in the brain, spine or near vascular structures)	• ^{18}F-FES (fluoroestradiol) PET/CT scan (CPT® 78815 or CPT® 78816)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Individuals treated with Enhertu® (fam-trastuzumab deruxtecan) in the adjuvant setting	• High-resolution CT Chest without contrast (CPT® 71250) ◦ Baseline if not already done within past 4 weeks ◦ Every 12 weeks while on Enhertu® therapy ▪ For patients receiving Enhertu® concurrent with radiation therapy, an additional scan is medically necessary at the end of radiation at approximately week 6 ◦ End of treatment with Enhertu® (5-7 weeks after last cycle) ◦ For suspected or known ILD, see **Interstitial Lung Disease (ILD)/ Diffuse Lung Disease (DLD) (CH-11.1)** ◦ HRCT (CPT® 71250) can be done per the above criteria if previous diagnostic CT Chest with contrast (CPT® 71260) was not adequate. HRCT is done with a thinner-slice protocol that can provide additional details to help determine ILD subtype.

Evidence Discussion

Breast MRI has been shown to predict extent of pathological tumor response in the breast and lymph nodes after neoadjuvant systemic therapy better than conventional imaging, although may over- or under-estimate residual tumor size.[35]

While some authors have found the use of MRI to be helpful in terms of estimating size of ipsilateral breast tumor recurrences and finding multifocal or multicentric disease[27], others have found that the addition of MRI in this context did not significantly change management and increased time to definitive therapy.[26] However, as previously noted, MRI may be a useful adjunct in situations where conventional imaging is inconclusive.

As individuals with symptoms for distant metastatic disease would have had systemic staging prior to neoadjuvant chemotherapy and/or surgery, there is no indication to repeat these until treatment is completed. However, for individuals with metastatic disease, NCCN guidelines recommended CT Chest, Abdomen, and Pelvis with contrast

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

every 2-4 cycles of chemotherapy or every 2-6 months of endocrine therapy and bone scan is recommended every 4-6 cycles of chemotherapy or every 2-6 months of endocrine therapy. Restaging using these modalities is also advised if there is concern for progression of disease. They noted that PET/CT is not routinely medically necessary for restaging "because of the absence of a reproducible, validated, and widely accepted set of standards for disease activity assessment". PET is instead preferred to be reserved as a problem-solving tool when conventional imaging is inconclusive. Additionally, NCCN noted sodium fluoride PET/CT may be helpful to detect bone metastases where other imaging is inconclusive.[1]

Breast Cancer – Surveillance/Follow-up (ONC-11.4)

ON.BC.0011.4.U
v3.0.2026

Indication	Medically Necessary Imaging Study
Measurable metastatic disease on maintenance therapy or being monitored off therapy	ANY or ALL of the following, every 3 months for up to 5 years after completion of active treatment: • CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast • Bone scan (CPT® 78306) (see also: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes)
• Asymptomatic non-metastatic disease • Individuals receiving post-operative adjuvant therapy	• No advanced imaging
Individuals with a personal history of breast cancer (not treated with bilateral mastectomy)	• Annual MRI Breast Bilateral without and with contrast (CPT® 77049)

Evidence Discussion

NCCN guidelines suggested that "the utility of MRI in follow-up screening of most patients with prior breast cancer is undefined", but recommend annual MRI in individuals with a personal history of breast cancer who were either younger than age 50 or who have dense breasts.[1] ACR also addressed the use of MRI breast in individuals with dense breast tissue. They did not differentiate between heterogeneously and extremely dense breasts in the recommendation. ACR considered dense breasts to be heterogeneously dense (Category C) and extremely dense (Category D).[29] As individuals with breast cancer may have residual breast tissue in the ipsilateral or contralateral breast for which certain genetic mutations may increase the risk of subsequent cancers, breast MRI would also be medically necessary in such individuals.[1] Individuals with a clinical lifetime risk estimated to be ≥20% lifetime risk prior to their diagnosis of breast cancer and/or who had a history of ADH or lobular neoplasia would have been candidates for breast cancer screening with

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

breast MRI regardless (see BR 5.1) and therefore, would equally be eligible for this screening modality after breast cancer treatment, as long as they had not had bilateral mastectomies. Individuals who have had bilateral mastectomies have little residual tissue, and therefore, surveillance with breast imaging would be of little value. A meta-analysis found that the rate of occult cancer in individuals with mastectomy and the rate at which MRI detected cancer in individuals after mastectomy was well below the current BIRADS benchmark for women with genetic predispositions to cancer.[25]

The NCCN guidelines stated "In the absence of clinical signs and symptoms suggestive of recurrent disease, there is no indication for laboratory or imaging studies for metastases screening".[1] This is in keeping with ASCO's Choosing Wisely guideline which similarly recommended against surveillance testing with biomarkers or imaging for asymptomatic breast cancer in individuals who have been treated with curative intent.[28] Several studies have shown no benefit from routine imaging which can result in unnecessary radiation exposure and biopsies, and lead to misdiagnosis and treatment related complications.[24] A study also found that more intensive screening for metastasis did not result in improved survival.[22]

Bone and Soft Tissue Sarcomas – General Considerations (ONC-12.1)

ON.SS.0012.1.A

v3.0.2026

- Sarcomas are tumors of mesenchymal origin, classified as high-, intermediate-, and low-grade (G) tumors (sometimes described as “spindle cell” cancers). They can arise in any bony, cartilaginous, smooth muscle, skeletal muscle, or cardiac muscle tissue.
- Malignant nerve sheath tumor cell types should be imaged as high-grade sarcoma.
- Sarcomas occur in both adult and pediatric individuals, but some are more common in one age group than the other. Unless specified below, individuals age ≥18 years old should be imaged according to this guideline section.
- Exceptions include:
  - Rhabdomyosarcoma in individuals of all ages should be imaged according to guidelines in **Rhabdomyosarcoma (RMS) (PEDONC-8.2)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
  - Osteogenic sarcoma (Osteosarcoma) in individuals of all ages should be imaged according to guidelines in **Osteogenic Sarcoma (OS) (PEDONC-9.3)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
  - Ewing sarcoma and Primitive Neuroectodermal Tumor in individuals of all ages should be imaged according to guidelines in **Ewing Sarcoma and Primitive Neuroectodermal Tumors (ESFT) (PEDONC-9.4)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
  - Kaposi’s sarcoma in individuals of all ages should be imaged according to guidelines in **Kaposi’s Sarcoma (ONC-31.10)**.
  - See: **Uterine Cancer (ONC-22)** for imaging recommendations for uterine sarcoma.
  - Desmoplastic small round cell tumor in individuals of all ages should be imaged according to guidelines in **Non-Rhabdomyosarcoma Soft Tissue Sarcomas (NRSTS) (PEDONC-8.3)** in the Pediatric and Special Populations Oncology Imaging Guidelines.

Evidence Discussion

The choice of imaging modality is driven by the primary tumor site. Cross sectional imaging of the primary site with MRI with and without contrast or CT with contrast is recommended for best illustration of anatomic detail and vascular and nodal involvement and provides flexibility for clinician discretion for choice of modality for all sites for maximum tumor definition with consideration of minimizing radiation exposure.[1,2]
CT is superior for evaluation for metastatic disease of the lung, which is medically necessary for all individuals with a newly diagnosed malignant sarcoma. Imaging both

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

with and without contrast for evaluation of metastatic disease to the lung is not medically necessary as this exposes individuals to higher radiation doses without significant clinical benefit.

Soft Tissue Sarcomas – Initial Work-up/ Staging (ONC-12.2)

ON.SS.0012.2.A
v3.0.2026

Indication	Medically Necessary Imaging Study
All individuals with biopsy-proven soft tissue sarcoma, regardless of histology	• CT Chest with (CPT® 71260) or CT Chest without (CPT® 71250) contrast • MRI without and with contrast of involved area ◦ CT of involved area if contraindication to MRI
ANY of the following: • Angiosarcoma • Alveolar soft part sarcoma • Clear cell sarcoma • Epithelioid sarcoma • Hemangiopericytoma • Leiomyosarcoma • Liposarcoma • Retroperitoneal or intra-abdominal primary site (including pelvic primary site) • Other histologies documented to have propensity for lymphatic spread and deep-seated tumors	In addition to the above, one of the following combinations: • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast • MRI Abdomen (CPT® 74183) with and without contrast and CT Pelvis (CPT® 72193) with contrast • CT Abdomen (CPT® 74160) with contrast and MRI Pelvis (CPT® 72197) without and with contrast
ANY of the following: • Myxoid round cell liposarcoma • Angiosarcoma • Alveolar soft part sarcoma • Cardiac sarcoma • Neurologic signs or symptoms raising suspicion of CNS metastases	In addition to the above: • MRI Brain without and with contrast (CPT® 70553) • MRI Cervical/Thoracic/Lumbar Spine without and with contrast (CPT® 72156, CPT® 72157, and CPT® 72158)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Leiomyosarcoma	In addition to the above: • Bone scan (CPT® 78306) (see also: **Nuclear Medicine (NM) Imaging in Oncology [ONC-1.3]** for additional bone scan codes)
ANY of the following: • Grade of tumor in doubt following biopsy • Conventional imaging suggests solitary metastasis amenable to surgical resection • Inconclusive conventional imaging • Prior to planned neoadjuvant therapy	• PET/CT (CPT® 78815 or CPT® 78816)
Desmoid Tumors	ONE of the following: • CT without contrast or with contrast of the affected body part • MRI without contrast or without and with contrast of the affected body part • Imaging of lung, lymph node, and metastatic site for these tumors is not medically necessary
Myxoid/round cell liposarcoma	In addition to the above studies, whole-body MRI (CPT® 76498) is medically necessary for a baseline assessment
Dermatofibrosarcoma Protuberans (DFSP)	ONE of the following: • CT without contrast or with contrast of the affected body part • MRI without contrast or without and with contrast of the affected body part • CT Chest with (CPT® 71260) or without (CPT® 71250) contrast for: ◦ Pulmonary symptoms ◦ Abnormal chest x-ray ◦ Sarcomatous differentiation

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Malignant phyllodes tumor of the breast (not benign or borderline)	ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Breast bilateral without and with contrast (CPT® 77049)

Evidence Discussion

- PET/CT is medically necessary where the grade of tumor is in doubt following biopsy or to confirm oligometastatic disease amenable to local treatment, to support treatment decision making. NCCN also supported the use of PET/CT for initial staging prior to planned neoadjuvant therapy. It is also a useful tool to follow inconclusive conventional imaging.[1]
- Different subtypes of soft tissue sarcomas have different patterns of spread; thus, a histologic diagnosis is essential to determine imaging strategy.
- Abdominal and pelvic imaging is not medically necessary for extremity, trunk, or head and neck primary sites, unless documented histologies with propensity for lymphatic spread.[14] Due to the propensity of myxoid and round cell liposarcomas for leptomeningeal spread, initial evaluation of the spine with MRI is medically necessary. MRI of the brain is medically necessary for those with CNS signs and symptoms, and for all individuals with angiosaroma, alveolar soft part sarcomas, and cardiac sarcoma.[1]
- For desmoid tumors, disease biology and patterns of recurrence do not support metastatic disease workup, CT Chest, or body areas outside of the primary site, as they subject individuals to additional radiation and incidental finding risk.[7]
- For dermatofibrosarcoma protuberans (DFSP), CT Chest is medically necessary for sarcomatous differentiation as noted for other sarcoma histologies above, or for pulmonary symptoms. In the absence of these features, CT exposes to risk with no statistically significant clinical benefit.[10,15]

Soft Tissue Sarcomas – Restaging/ Recurrence (ONC-12.3)

ON.SS.0012.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
ANY of the following: • After preoperative radiotherapy • After surgical resection	• MRI without and with contrast or CT with contrast of affected body area • CT Chest with contrast (CPT® 71260) OR without contrast (CPT® 71250) (if the primary site is the chest, MRI Chest without and with contrast (CPT® 71552) or MRI Chest with contrast CPT® 71550))
Baseline end of therapy evaluation, including completion of adjuvant radiotherapy	• Same studies as initial work-up (See **Soft Tissue Sarcomas - Initial Work-up/Staging (ONC-12.2)**)
ANY of the following: • Differentiate tumor from radiation or surgical fibrosis • Determine response to neoadjuvant therapy • Confirm oligometastatic disease prior to curative intent surgical resection	• PET/CT (CPT® 78815 or CPT® 78816) ◦ If treated with radiation therapy, PET/CT no sooner than 12 weeks (3 months) post completion of radiation therapy
EITHER of the following: • Chemotherapy response for individuals with measurable disease • Individuals on neoadjuvant treatment without known lung involvement	• CT with contrast or MRI without and with contrast of affected body area every 2 cycles

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Unresectable or metastatic disease on chemotherapy	Every 2 cycles: • CT with contrast or MRI without and with contrast of affected body area AND • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250)
Recurrence suspected	• Repeat all imaging for initial workup of specific histology and/or primary site and other symptomatic areas (See **Soft Tissue Sarcomas - Initial Work-up/ Staging (ONC-12.2)**)
Preoperative planning prior to resection	ANY or ALL of the following: • MRI without contrast or without and with contrast of involved area • CT (contrast as requested) of involved area
Dermatofibrosarcoma Protuberans (DFSP)	• CT without contrast or with contrast of the affected body part or MRI without contrast or without and with contrast of the affected body part • CT Chest with contrast (CPT® 71260) or CT Chest without (CPT® 71250) contrast for: ◦ Known prior thoracic disease ◦ New or worsening pulmonary symptoms ◦ New or worsening chest x-ray ◦ Sarcomatous differentiation
Malignant phyllodes tumor of the breast (not benign or borderline) after resection or radiotherapy	See **Soft Tissue Sarcomas - Surveillance/Follow-up (ONC-12.4)**

Evidence Discussion

- Local therapy is a cornerstone of treatment for sarcomas. Cross-sectional imaging of primary site, with modality used at diagnosis specific to tumor site, is medically necessary after pre-operative radiotherapy, and after resection of adjuvant radiotherapy to determine response, as well as for pre-operative planning prior to resection and every two cycles of treatment during active therapy. NCCN

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

supported imaging for a baseline at the end of therapy. In the absence of known lung involvement or pulmonary symptoms, restaging of lung on active treatment does not provide benefit in most histologies and exposes individuals to additional radiation and risk of incidental findings.[1]

- NCCN indicated that PET/CT may be useful for therapy response. Individuals with baseline tumor SUVmax ≥6 and <40% decrease in FDG avidity after neoadjuvant therapy are at high risk for disease recurrence. Pretreatment tumor SUVmax and change in SUVmax after neoadjuvant therapy has been shown to identify individuals at high risk of tumor recurrence and may be used to identify individuals most likely to benefit from additional chemotherapy.[13] PET/CT is medically necessary to assess neoadjuvant therapy response, to differentiate scarring from disease, or to confirm oligometastatic disease prior to resection.[c1,13]

Soft Tissue Sarcomas - Surveillance/ Follow-up (ONC-12.4)

ON.SS.0012.4.A
v3.0.2026

Indication	Medically Necessary Imaging Study
For any of the following: • Retroperitoneal/intra-abdominal primary site (including pelvic primary site) • Angiosarcoma • Epithelioid sarcoma	ANY or ALL of the following every 3 months for 3 years, then every 6 months for 2 more years, then annually: • CT Chest with (CPT® 71260) or without (CPT® 71250) contrast • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast or MRI without and with contrast of any other involved body areas
Myxoid/round cell liposarcoma	ANY or ALL of the following every 3 months for 2 years, then every 6 months for 2 more years, then annually: • CT Chest with (CPT® 71260) or without (CPT® 71250) contrast • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast or MRI without and with contrast of any other involved body areas • MRI Cervical/Thoracic/Lumbar Spine without and with contrast (CPT® 72156, CPT® 72157, and CPT® 72158)
Low-grade/Stage I extremity or trunk, primary site	ANY or ALL of the following every 6 months for 2 years, then annually thereafter: • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) • CT with contrast, MRI without contrast, or MRI without and with contrast of primary site

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Any soft tissue sarcoma not addressed elsewhere in these surveillance guidelines	ANY or ALL of the following every 3 months for 2 years, then every 6 months for 2 more years, then annually: • CT with contrast, MRI without contrast, or MRI without and with contrast of primary site • CT Chest with (CPT® 71260) or without (CPT® 71250) contrast • CT with contrast or MRI without and with contrast of any other involved body areas
ANY of the following: • Angiosarcoma • Alveolar soft part sarcoma • Cardiac sarcoma	In addition to the above studies: • MRI Brain without and with contrast (CPT® 70553) annually For surveillance of individuals with known brain metastases, see: **Brain Metastases (ONC-31.3)**
Desmoid tumors	ONE of the following every 3 months for 3 years, then every 6-12 months: • CT without contrast or with contrast of the affected body part • MRI without contrast or without and with contrast of the affected body part
Dermatofibrosarcoma Protuberans	• No routine imaging unless clinical signs/symptoms of recurrence
Malignant phyllodes tumor of the breast (not borderline or benign)	ANY or ALL of the following every 3-6 months for 3 years, then every 6 months for 2 years, and then annually • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Breast bilateral without and with contrast (CPT® 77049)

Evidence Discussion

Time frames, modality, and body site for surveillance by histology are based on tumor recurrence patterns specific to primary site and tumor biology. PET/CT is not medically

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

necessary for asymptomatic surveillance, as this can lead to unnecessary radiation exposure and invasive procedures or excess treatment.[1,7,10]

Gastrointestinal Stromal Tumor (GIST) (ONC-12.5)

ON.SS.0012.5.A
v3.0.2026

General Considerations

- GISTs are mesenchymal neoplasms of the gastrointestinal (GI) tract, mostly found in the stomach and upper small bowel, commonly metastasizing to the liver and abdominal cavity and primarily treated with surgery.
- Recurrence risk of GIST is estimated by prognostic model based on location, size of primary tumor, and mitotic rate per high power field (HPF).
- High-risk category includes any tumor >5cm with >5 mitoses/50 HPF and any tumors >10cm in size regardless of mitotic rate.

Indication	Medically Necessary Imaging Study
Suspected/Diagnosis	• CT Abdomen and Pelvis with contrast (CPT® 74177)
Initial Work-up/Staging	• CT Chest (CPT® 71260) with contrast or CT Chest without contrast (71250) and • CT Abdomen and Pelvis (CPT® 74177) with contrast, if not already performed
In addition to the above imaging for initial staging of either of the following: • Liver lesions noted on initial CT • Preoperative assessment of liver	• MRI Abdomen without and with contrast (CPT® 74183)
Monitoring response to treatment (every 8 to 12 weeks) in any of the following: • Unresectable primary disease • Metastatic disease • Resectable disease with significant morbidity	EITHER of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)

Proprietary Information of UnitedHealthcare.

Indication	Medically Necessary Imaging Study
Additional treatment response, in addition to the above imaging, for known or suspected chest involvement	• CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250)
Evaluation of inconclusive findings on conventional imaging	• PET/CT (CPT® 78815)
Surveillance for any of the following: • Incompletely resected • Metastatic disease • High-risk disease	Every 3 months for 5 years, then annually: • CT Abdomen and Pelvis with contrast (CPT® 74177)
Surveillance for completely resected, low-risk disease	Every 6 months for 5 years, then annually: • CT Abdomen and Pelvis with contrast (CPT® 74177)
Known or suspected recurrence	ANY or ALL of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) for known or suspected liver involvement • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) for known or suspected chest involvement

Evidence Discussion

Suspected/Diagnosis and Initial Staging

CT Abdomen and Pelvis are recommended by NCCN for suspected GIST.[3]

NCCN stated that CT is the "imaging modality of choice to characterize an abdominal mass, as well as to evaluate its extent and the presence or absence of metastasis at the initial staging workup".[3] While CT Chest is medically necessary to rule out metastatic disease in biopsy-proven GIST, advanced imaging prior to confirmation of diagnosis may expose individuals to unnecessary radiation and increased irrelevant incidental findings. MRI is an adjunct to CT to provide anatomical definition of liver metastases.[3] NCCN noted that PET/CT is not a substitute for diagnostic CT, which has superior sensitivity

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

for this tumor site, but PET/CT is supported for inconclusive CT findings as it can "help differentiate tumor from necrotic or inactive scar tissue, malignant from benign tissue, and recurrent tumor from nondescript benign changes".[3].

Restaging

Abdominal/pelvic imaging every 8-12 weeks to assess response to TKI is medically necessary given the typical response timeframe for this treatment.[17] NCCN stated "since there is a 95% correlation between the information from regular contrast-enhanced CT and PET/CT, CT with IV contrast is the preferred routine imaging modality for patients with GIST on TKI therapy".[3] More frequent imaging may lead to premature or incorrect treatment decisions. Chest imaging in the absence of prior chest findings or signs and symptoms of chest involvement is low-yield and not recommended by NCCN, as it poses potential for risk of increased incidental findings and increased radiation exposure.[3]

Surveillance

Surveillance guidance from NCCN stated that imaging should be performed every three to six months for five years. More frequent surveillance imaging is recommended by NCCN for high-risk tumors. Less frequent imaging is acceptable for low-risk tumors.[3]

Bone Sarcomas – Initial Work-up/Staging (ONC-12.6)

ON.SS.0012.6.A
v3.0.2026

- Osteogenic sarcoma (Osteosarcoma) in individuals of all ages should be imaged according to guidelines in **Osteogenic Sarcoma (OS) (PEDONC-9.3)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
- Ewing sarcoma and Primitive Neuroectodermal Tumor in individuals of all ages should be imaged according to guidelines in **Ewing Sarcoma and Primitive Neuroectodermal Tumors (ESFT) (PEDONC-9.4)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
- Extraskeletal myxoid chondrosarcoma in individuals of all ages should be imaged according to Soft Tissue Sarcomas (**ONC-12.2**, **ONC-12.3**, and **ONC-12.4**).
- Bone sarcomas not addressed in this guideline are exceedingly rare and will be evaluated on a case-by-case basis.

Indication	Medically Necessary Imaging Study
Chondrosarcoma • Low-grade intra-compartmental • High-grade (grade II or grade III) • Clear cell • Extra-compartmental	ANY or ALL of the following: • MRI without contrast or without and with contrast of involved area • CT (contrast as requested) of involved area • CT Chest with (CPT® 71260) or without (CPT® 71250) contrast
Dedifferentiated chondrosarcoma	See: **Osteogenic Sarcoma (OS) (PEDONC-9.3)** for imaging
Mesenchymal chondrosarcoma	See: **Ewing's Sarcoma Family of Tumors (PEDONC-9.4)** for imaging

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Chordoma	ANY or ALL of the following: • MRI without contrast or without and with contrast of involved area • CT (contrast as requested) of involved area • CT Chest with (CPT® 71260) or without (CPT® 71250) contrast • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Cervical (CPT® 72156), Thoracic (CPT® 72157), and Lumbar (CPT® 72158) Spine without and with contrast • Bone scan (CPT® 78306) (see also: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes)
Chordoma with inconclusive findings on conventional imaging	PET/CT (CPT® 78815 or CPT® 78816)

Evidence Discussion

The choice of imaging modality is driven by the primary tumor site. Cross-sectional imaging of the primary site with MRI with and without contrast or CT with contrast is recommended for best illustration of anatomic detail and vascular and nodal involvement. Our guideline provides flexibility for provider discretion for choice of modality for all sites. Providers should choose modality expected to offer maximum primary tumor definition with consideration of minimizing radiation exposure.[2] CT is more sensitive and specific than MRI for evaluation for metastatic disease of the lung and is medically necessary for all individuals with a newly diagnosed malignant sarcoma. Imaging both with and without contrast for evaluation of metastatic disease to the lung is not medically necessary as this exposes individuals to higher radiation doses without significant clinical benefit. CT either with or without contrast should be selected at discretion of the provider.

Chordomas have a propensity for the distant disease at presentation including spine, so unlike other bone sarcomas, imaging of the abdomen and pelvis with contrasted CT as well as bone scan and MRI of the spine are medically necessary. FDG PET/CT is medically necessary only for inconclusive conventional imaging. PET is not generally medically necessary for initial staging of other histologies discussed in this section due to low sensitivity and specificity.[2]

Bone Sarcomas – Restaging/Recurrence (ONC-12.7)

ON.SS.0012.7.A
v3.0.2026

- Bone sarcomas not addressed in this guideline are exceedingly rare and will be evaluated on a case-by-case basis.

Indication	Medically Necessary Imaging Study
Chondrosarcoma • Low-grade intra-compartmental • High-grade (grade II or grade III) • Clear cell • Extra-compartmental	ANY or ALL of the following, after completion of radiotherapy or every 2 cycles of chemotherapy: • MRI without contrast or without and with contrast of involved area • CT (contrast as requested) of involved area • CT Chest with (CPT® 71260) or without (CPT® 71250) contrast
Suspected recurrence of atypical cartilaginous tumor (low-grade intra-compartmental appendicular tumor)	ANY or ALL of the following: • MRI without contrast or without and with contrast of involved area or CT (contrast as requested) of involved area • CT Chest with (CPT® 71260) or without (CPT® 71250) contrast • Bone scan (CPT® 78306) (see also: **Nuclear Medicine (NM) Imaging in Oncology [ONC-1.3]** for additional bone scan codes)
Dedifferentiated chondrosarcoma	See: **Osteogenic Sarcoma (OS) (PEDONC-9.3)** for imaging recommendations
Mesenchymal chondrosarcoma	See: **Ewing's Sarcoma Family of Tumors (PEDONC-9.4)** for imaging recommendations

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Chordoma	ANY or ALL of the following, after completion of radiotherapy or every 2 cycles of chemotherapy: • MRI without contrast or without and with contrast of involved area • CT (contrast as requested) of involved area • Bone scan (CPT® 78306) (see also: **Nuclear Medicine (NM) Imaging in Oncology [ONC-1.3]** for additional bone scan codes)
Chordoma with inconclusive findings on conventional imaging	PET/CT (CPT® 78815 or CPT® 78816)

Evidence Discussion

CT Chest is medically necessary for restaging for all bone sarcomas, as well as MRI of primary site. CT of other body areas is driven by clinical symptoms and patterns of spread at primary site and not routine across all cell types .[2] PET/CT for restaging is not routinely medically necessary but may be used for inconclusive conventional imaging.[2]

Bone Sarcomas – Surveillance/Follow-up (ONC-12.8)

ON.SS.0012.8.A
v3.0.2026

Indication	Medically Necessary Imaging Study
• Intra-compartmental Chondrosarcoma	ANY or ALL of the following every 6-12 months for 2 years, then annually for 10 years: • Plain x-ray of primary site ◦ MRI without and with contrast for new findings on plain x-ray or new/worsening clinical symptoms • Chest x-ray ◦ CT Chest with (CPT® 71260) or without (CPT® 71250) contrast for new findings on chest x-ray, or new/worsening signs/symptoms
• Grade I, II, or III Chondrosarcoma • Clear Cell Chondrosarcoma • Extra-compartmental Chondrosarcoma • Low-grade extra-compartmental appendicular tumors	ANY or ALL of the following every 6 months for 5 years, then annually for 10 years: • Plain x-ray of primary site ◦ MRI without and with contrast for new findings on plain x-ray or new/worsening clinical symptoms • CT Chest with (CPT® 71260) **or** CT Chest without (CPT® 71250) contrast
Dedifferentiated chondrosarcoma	See: **Osteogenic Sarcoma (OS) (PEDONC-9.3)** for imaging recommendations
Mesenchymal chondrosarcoma	See: **Ewing's Sarcoma Family of Tumors (PEDONC-9.4)** for imaging recommendations

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Chordoma	• Plain x-ray of primary site every 6 months for 5 years and then annually until year 10 ◦ MRI without and with contrast for new findings on plain x-ray or new/worsening clinical symptoms. • Chest x-ray every 6 months for 5 years and then annually until year 10 ◦ CT Chest with (CPT® 71260) or without (CPT® 71250) contrast annually or for evaluation of any new findings on chest x-ray or new/worsening signs/symptoms

Evidence Discussion

Data did not show an overall survival benefit with advanced imaging surveillance of sarcomas. Less than 20% of local recurrences are detected based on advanced imaging surveillance in asymptomatic individuals. Sensitivity and specificity of chest imaging are higher in grade two or higher disease.[18]

For grades I-III disease, plain x-ray is medically necessary as the primary tool for primary site surveillance, with cross sectional advanced imaging for signs and symptoms of progression or changes on x-ray. Chest imaging is medically necessary with either plain imaging or CT. Recurrence beyond 10 years is rare; asymptomatic surveillance imaging beyond 10 years is low yield and is not generally medically necessary.[2]

Benign Bone Tumors – General Considerations (ONC-12.9)

ON.SS.0012.9.A
v3.0.2026

- Variety of diagnoses, including osteoid osteochondroma, chondroblastoma, desmoplastic fibroma, Paget's disease, osteoid osteoma, and others.
- Plain x-ray appearance is diagnostic for many benign bone tumors and advanced imaging is generally not medically necessary except for preoperative planning.
- MRI without and with contrast is the primary modality for advanced imaging of bone tumors and is medically necessary to help narrow differential diagnoses and determine whether biopsy is indicated.
- Some benign bone tumor types carry a risk of malignant degeneration over time, but routine advanced imaging surveillance has not been shown to improve outcomes for these individuals.
- MRI without and with contrast is medically necessary to evaluate new findings on plain x-ray new/worsening clinical symptoms not explained by a recent plain x-ray.
- There are no data to support the use of PET/CT in the evaluation of benign bone tumors, and PET requests are not medically necessary without biopsy confirmation of a malignancy.
- Other benign bone tumors should be imaged according to guidelines in **Bone Lesion (MS-10.2)** in the General Musculoskeletal Imaging Guidelines or **Mass Involving Bone (including Lytic and Blastic Metastatic Disease) (PEDMS-3.4)** in the Pediatric Musculoskeletal Imaging Guidelines.

Evidence Discussion

Many benign bone tumors have characteristic appearance on plain x-ray, particularly in conjunction with history, individual age, and size and growth characteristics. Lesions without aggressive appearing characteristics on x-ray generally do not require further evaluation. Advanced imaging modalities are medically necessary when x-ray is indeterminate for malignancy to determine management strategy. Thus, the advanced imaging guidelines in this section pertain to enchondromas, which often appear indeterminate on plain x-ray, and giant cell tumor of bone (GCTB), which have potential for malignant degeneration and metastasis.[2,19]

Benign Bone Tumors – Initial Work-up/ Staging (ONC-12.10)

ON.SS.0012.10.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Giant Cell Tumor of Bone (GCTB)	ANY or ALL of the following: • MRI without contrast or without and with contrast of involved area • CT (contrast as requested) of involved area • CT Chest with (CPT® 71260) or without (CPT® 71250) contrast • Bone scan (CPT® 78306) (see also: **Nuclear Medicine (NM) in Oncology [ONC-1.3]** for additional bone scan codes)
Enchondroma	• MRI without contrast or without and with contrast of primary site

Evidence Discussion

- Giant Cell Tumor of Bone
  - MRI can help distinguish malignant transformation, while complex bony anatomy maybe better visualized on CT. To establish management strategy, our guidelines support using both modalities for involved areas in alignment with NCCN and ACR.[2,16]
  - CT Chest and whole-body bone scan are medically necessary at time of initial staging given the malignant and metastatic potential of GCTB. CT Abdomen and Pelvis are not medically necessary without symptoms in these areas as this would not be a typical pattern of metastasis in the setting of malignant degeneration of GCTB. CT of abdomen and pelvis increases radiation exposure with low yield.[2]
- Enchondroma
  - MRI can help distinguish suspected enchondroma on plain film from other more malignant entities and is medically necessary for initial staging to confirm characteristic appearance.[19]

Benign Bone Tumors – Restaging/ Recurrence (ONC-12.11)

ON.ss.0012.11.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Giant Cell Tumor of Bone (GCTB)	ANY or ALL of the following, after completion of radiotherapy or every 2 cycles of chemotherapy: • MRI without contrast or without and with contrast of involved area • CT (contrast as requested) of involved area • Bone scan (CPT® 78306 (see also: **Nuclear Medicine (NM) Imaging in Oncology [ONC-1.3]** for additional bone scan codes)
Enchondroma	Plain films of primary site

Evidence Discussion

- GCTB
  - For individuals requiring chemotherapy, repeat of all imaging done at initial staging may be done every two cycles to assess treatment response or need to change therapy. For individuals treated with radiotherapy, repeat imaging may be done at completion of radiotherapy to verify treatment response and establish baseline for surveillance.[2,16]
- Enchondroma
  - Once initial staging with advanced imaging has been completed, plain films should be adequate to ensure stability or for suspected recurrence, restaging after local therapy, or surveillance. Further advanced imaging is generally low yield unless there are indeterminate findings on the plain films.[19]

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Benign Bone Tumors – Surveillance/ Follow-up (ONC-12.12)

ON.SS.0012.12.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Giant Cell Tumor of Bone (GCTB)	ANY or ALL of the following every 6-12 months for 4 years, then annually thereafter: • Plain x-ray of primary site ◦ MRI without and with contrast for new findings on plain x-ray, or new/worsening clinical symptoms • Chest x-ray ◦ CT Chest with (CPT® 71260) or without (CPT® 71250) contrast for new findings on chest x-ray, or new/worsening signs/ symptoms
Enchondroma	Plain films of primary site

Evidence Discussion

- GCTB
  - The role of advanced imaging in asymptomatic surveillance is not well established for GCTB. Though late recurrences can occur, there is not strong data to support advanced imaging over plain film in asymptomatic individuals. These guidelines allow advanced imaging if there are indeterminate findings on plain film, both for primary site and chest. Time frames for plain films are in alignment with NCCN. [2,16]
- Enchondroma
  - Once initial staging with advanced imaging has been completed, plain films should be adequate to ensure stability or further imaging for recurrence, restaging after local therapy, or surveillance . Further advanced imaging is generally low yield unless there are indeterminate findings on the plain films.[19]

Pancreatic Cancer – General Considerations (ONC-13.0)

ON.PC.0013.0.A

v3.0.2026

- This guideline refers only to adenocarcinoma of the exocrine pancreas, which accounts for over 90% of pancreatic malignancies. This guideline may also be used for cancer of the Ampulla of Vater.
- Neuroendocrine and carcinoid tumors of the pancreas are not included in this guideline, see: **Neuroendocrine Cancers and Adrenal Tumors (ONC-15)**.

Pancreatic Cancer – Screening Studies for Pancreatic Cancer (ONC-13.1)

ON.PC.0013.1.A
v3.0.2026

- Detailed history of any known inherited syndrome in the individual and detailed family history in first- and second-degree relatives, including the age and lineage, is essential to guide screening recommendations. See table below for age- and risk-specific screening recommendations.
- New onset of diabetes in individuals older than 50 has been recognized as a potential indicator of the development of pancreatic cancer. Approximately 1% of individuals in this category are diagnosed with cancer within 3 years. A prediction model has been established which identifies those individuals at greatest risk for pancreatic malignancy. The scoring system, known as ENDPAC (Enriching New-Onset Diabetes for Pancreatic Cancer) is based on 3 discriminatory factors, including change in blood glucose, change in weight, and age of onset at the time of the new diagnosis of diabetes. A score of >3 imparts an elevated risk of pancreatic cancer (3.6%), and these individuals should be screened. Screening is not medically necessary at this time for scores of 0-2.

Indications	Medically Necessary Imaging Study
Individuals who meet **BOTH** of the following criteria: • One or more first- or second-degree relative affected with pancreatic cancer **AND** • Known mutation carrier of ONE of the following genes: ◦ Lynch Syndrome (MLH1, MSH2, or MSH6 gene mutations) ◦ BRCA1 ◦ PALB2 mutation ◦ EPCAM ◦ TP53	• MRI Abdomen without and with contrast (CPT® 74183) or MRCP with 3D rendering (CPT® 74183 and CPT® 76376 or CPT® 76377) starting at age 50 or 10 years earlier than the youngest family member affected with exocrine pancreatic cancer, repeat annually

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indications	Medically Necessary Imaging Study
Individuals with family history of pancreatic cancer but no known genetic mutation: • Individuals with 2 relatives with pancreatic cancer where one is a first-degree relative • Individuals with 3 or more relatives with pancreatic cancer	• MRI Abdomen without and with contrast (CPT® 74183) or MRCP with 3D rendering (CPT® 74183 and CPT® 76376 or CPT® 76377) starting at age 45 or 10 years earlier than the youngest family member affected with exocrine pancreatic cancer, repeat annually
Pancreatic Cancer Kindred (individuals who have at least one first-degree relative with pancreatic cancer who in turn also has a first-degree relative with pancreatic cancer) and NO known genetic germline mutations	• MRI Abdomen without and with contrast (CPT® 74183) or MRCP with 3D rendering (CPT® 74183 and CPT® 76376 or CPT® 76377) starting at age 50 or 10 years earlier than the youngest family member affected with exocrine pancreatic cancer, repeat annually
Hereditary Pancreatitis (PRSS1, CPA1, and CTRC gene mutations)	• MRI Abdomen without and with contrast (CPT® 74183) or MRCP with 3D rendering (CPT® 74183 and CPT® 76376 or CPT® 76377) beginning at age 40 or 20 years after the first pancreatitis attack, repeat annually
Peutz-Jeghers Syndrome (LKB1/STK11 gene mutation)	• MRI Abdomen without and with contrast (CPT® 74183) or MRCP with 3D rendering (CPT® 74183 and CPT® 76376 or CPT® 76377) starting at age 30 or 10 years earlier than the youngest family member affected with exocrine pancreatic cancer, repeat annually ◦ Family history is not required to begin imaging at age 30

Indications	Medically Necessary Imaging Study
CDKN2A mutation (also known as p16, p16INK4a, and MTS1, FAMM-Familial Atypical Multiple Melanoma and Mole Syndrome)	• MRI Abdomen without and with contrast (CPT® 74183) or MRCP with 3D rendering (CPT® 74183 and CPT® 76376 or CPT® 76377) beginning at age 40 or 10 years earlier than the youngest family member affected with exocrine pancreatic cancer, repeat annually ◦ Family history is not required to begin imaging at age 40
• BRCA2 • ATM (Ataxia-Telangiectasia)	• MRI Abdomen without and with contrast (CPT® 74183) or MRCP with 3D rendering (CPT® 74183 and CPT® 76376 or CPT® 76377) starting at age 50 or 10 years earlier than the youngest family member affected with exocrine pancreatic cancer, repeat annually ◦ Family history is not required to begin imaging at age 50
Screening MRI reveals cystic lesion of the pancreas	• Repeat MRI Abdomen without and with contrast (CPT® 74183) or MRCP with 3D rendering (CPT® 74183 and CPT® 76376 or CPT® 76377) in 6 months
Screening MRI reveals indeterminate solid lesion	• CT Abdomen with contrast – pancreatic protocol (CPT® 74160) • Repeat MRI Abdomen without and with contrast (CPT® 74183) or MRCP with 3D rendering (CPT® 74183 and CPT® 76376 or CPT® 76377) in 3 months after the CT scan
Screening MRI reveals pancreatic stricture and/or dilation ≥6mm without a mass	• CT Abdomen with contrast – pancreatic protocol (CPT® 74160) • Repeat MRI Abdomen without and with contrast (CPT® 74183) or MRCP with 3D rendering (CPT® 74183 and CPT® 76376 or CPT® 76377) in 3 months after the CT scan

Evidence Discussion

International Cancer of the Pancreas Screening Consortium (CAPS) recommended screening for those with an estimated lifetime risk of pancreatic cancer >5% to facilitate early detection, as the survival of individuals diagnosed with advanced disease at presentation is extremely poor. Individuals may be high-risk due to family history of 2-3 relatives with pancreatic adenocarcinoma with first degree relative affected, or those with known deleterious genetic mutations in conjunction with one first- or second-degree relative with pancreatic adenocarcinoma.[3,14,17] Asymptomatic screening has not been shown to improve outcomes in those without an established lifetime risk of >5%, including those with only more distant relatives affected, a single relative affected and no known high-risk mutation, or those with mutations whose risk is unknown.[3,14]

The lifetime risk and age at presentation varies with each genetic mutation. Updated CAPS recommendations generally support imaging at age 50 or ten years younger than the age of the youngest relative with pancreatic adenocarcinoma. These guidelines align with CAPS and NCCN with multiple exceptions to this to allow screening at younger ages for individuals with mutations known to be higher risk or present at younger ages.[17,13] US Preventative Services Task Force (USPSTF) did not generally recommend pancreatic cancer screening, though they did not evaluate individuals with high-risk criteria in this data. The USPSTF noted that screening has moderate risk due to unnecessary imaging and management of incidental findings.[4] These findings further support that screening for those that do not meet the clearly defined risk factors listed in the guideline is not medically necessary.

MRI without and with contrast shows up to 93% sensitivity for pancreatic lesions and better illustrates pancreatic ducts, which may indirectly identify pancreatic malignancy, and is the preferred modality for screening for most individuals in these guidelines. This is superior to both CT and endoscopic ultrasound, which may not detect smaller lesions.[15] CT pancreatic protocol is medically necessary in these guidelines if indeterminate findings on MRI in the interest of early detection.

A unique group is individuals with new onset diabetes and ENDPAC score >3. These individuals are at an elevated risk of developing pancreatic cancer within 6 months even in the absence of family history or known deleterious mutations. MRI or CT is medically necessary in this population at diagnosis of diabetes and again in 6 months.[16,12]

Pancreatic Cancer – Suspected/ Diagnosis (ONC-13.2)

ON.PC.0013.2.A
v3.0.2026

Indication	Medically Necessary Imaging Study
For any suspected symptoms only (e.g., epigastric pain, weight loss, pain radiating to back, etc.)	• Ultrasound (CPT® 76700 or CPT® 76705) • Also see: **Epigastric Pain and Dyspepsia (AB-2.5)**
Symptoms suspicious for pancreatic cancer AND any one of the following: • Abnormal labs (e.g., elevated CA 19-9, ALKP, bilirubin, or GGTP) • Abnormal physical exam findings (e.g., abdominal mass) • Abnormal or non-diagnostic ultrasound/ERCP	Any ONE of the following: • CT Pancreatic Protocol (CT Abdomen with contrast with dual phase imaging, CPT® 74160) • MRI Abdomen without and with contrast (CPT® 74183) or MRCP with 3D rendering (CPT® 74183 and CPT® 76376 or CPT® 76377)
Preoperative studies for potentially resectable tumors without confirmed histologic diagnosis	• See: **Pancreatic Cancer – Initial Work-up/ Staging (ONC-13.3)**

Evidence Discussion

For individuals with symptoms suspicious for pancreatic cancer with abnormal labs and physical findings or abnormal or non-diagnostic ultrasound or ERCP, CT pancreatic protocol (abdomen without and with contrast) or MRI abdomen without and with contrast are medically necessary. CT pancreatic protocol has a sensitivity and specificity of 90 and 87%, respectively.[20,19] Sensitivity and specificity of MRI are 89 and 90%, respectively.[20,19] CT has the advantage of being less costly, more accessible, and faster, but exposes the individual to more radiation. MRI may be more sensitive for visualization of pancreatic ducts and has less radiation exposure, but can be less accessible, more costly, takes longer, and can pose difficulties with claustrophobia and has more contraindications.[19] Given their similar sensitivity and specificity, these guidelines allow flexibility for individuals and providers to weigh risks and benefits for each individual for suspected disease.

Pancreatic Cancer – Initial Work-up/ Staging (ONC-13.3)

ON.PC.0013.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
All individuals	• CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with (CPT® 74177) or CT Abdomen and Pelvis without and with contrast (CPT® 74178)
For any of the following: • Preoperative planning • CT insufficient to determine resectability	• MRI Abdomen without and with contrast (CPT® 74183) OR MRCP with 3D rendering (CPT® 74183 and CPT® 76376 or CPT® 76377) AND/ OR • CTA Abdomen (CPT® 74175) and Pelvis (CPT® 72191) OR MRA Abdomen (CPT® 71485) and Pelvis (CPT® 72198)
Evaluation of indeterminate liver lesions	• MRI Abdomen without and with contrast (CPT® 74183) OR • MRCP with 3D rendering (CPT® 74183 and CPT® 76376 or CPT® 76377)
No evidence of metastatic disease on CT or MRI AND any of the following: • Equivocal or indeterminate conventional imaging findings • Markedly elevated CA 19-9 • Large primary tumor(s) • Enlarged regional lymph nodes • Planned neoadjuvant therapy	• PET/CT (CPT® 78815)

Evidence Discussion

For biopsy proven pancreatic adenocarcinoma, evaluation for metastatic disease with contrasted CTs of the chest, abdomen and pelvis are medically necessary, given that approximately 80% of individuals have metastatic or locally advanced disease at

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

presentation.[20] Resectability has a dramatic impact on prognosis, and MRI abdomen with and without contrast is medically necessary in addition to CT if CT is insufficient to determine resectability, for preoperative planning, or to evaluate indeterminate liver lesions.[1] Given the high incidence of metastatic disease at presentation, if high-risk features are noted but no metastatic disease is visible on conventional imaging, a PET/CT is medically necessary to assess for occult extra-pancreatic metastatic disease, in alignment with the NCCN. This is not a substitute for a diagnostic-quality contrasted CT or MRI, which is superior for detecting pancreatic disease.[1,19] PET/MRI has a weak expert consensus without sufficient data, and as such, these guidelines do not routinely support this modality.[1,21,22,24]

Pancreatic Cancer – Restaging/ Recurrence (ONC-13.4)

ON.PC.0013.4.A
v3.0.2026

Indication	Medically Necessary Imaging Study
For ANY of the following: • After neoadjuvant therapy • Post-operative baseline • Suspected recurrence	• CT Chest with contrast (CPT® 71260) • Abdominal imaging with one of the following, using same modality as used at initial evaluation: ◦ CT Abdomen and Pelvis with (CPT® 74177) ◦ CT Abdomen and Pelvis without and with contrast (CPT® 74178) ◦ MRI Abdomen without and with contrast (CPT® 74183) ◦ MRCP with 3D rendering (CPT® 74183 and CPT® 76376 or CPT® 76377) • CT with contrast of other involved or symptomatic areas
Unresectable disease or metastatic disease on chemotherapy	Every 2 cycles of treatment (commonly every 6 to 8 weeks): • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with (CPT® 74177) or CT Abdomen and Pelvis without and with contrast (CPT® 74178) • CT with contrast of other involved or symptomatic areas
Unexplained elevated liver enzymes or inconclusive recent CT abnormality	• MRI Abdomen without and with contrast (CPT® 74183) or MRCP with 3D rendering (CPT® 74183 and CPT® 76376 or CPT® 76377)
If complete surgical resection was initial therapy	• See: **Pancreatic Cancer – Surveillance/Follow-up for surveillance imaging (ONC-13.5)**
Inconclusive findings on conventional imaging	• PET/CT (CPT® 78815)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion

For individuals with unresectable or metastatic disease on chemotherapy, imaging of the chest, abdomen and pelvis with contrast (or without and with contrast for the abdomen and pelvis) are medically necessary every 2 cycles of treatment, given the high rate of progression and metastases, to allow for prompt consideration of changes in treatment. CT of any involved or symptomatic area is also medically necessary. The same imaging is medically necessary after neoadjuvant chemoradiation to assess resectability and rule out metastatic disease. Resection is the mainstay of curative therapy in pancreatic cancer, but only 20% of individuals achieve this status. Individuals with unresectable or metastatic disease are unlikely to benefit from surgery, thus pre-operative evaluation for metastasis is essential to minimize unnecessary surgical risk.[20,1] As noted in the initial staging section, both CT and MRI have advantages and disadvantages. MRI is more specific for liver disease and offers better soft tissue differentiation for inconclusive findings.[1,24] The same imaging guidance applies to suspected recurrence of disease. Restaging studies are also medically necessary as a post-operative baseline, to ensure the absence of residual disease and make decisions regarding adjuvant treatment, and to ensure accurate comparison for surveillance imaging.

Pancreatic Cancer – Surveillance/Follow-up (ONC-13.5)

ON.PC.0013.5.A
v3.0.2026

Indication	Medically Necessary Imaging Study
All individuals (other than resected ampullary cancer)	Every 3 months for 2 years, then annually: • CT Chest with contrast (CPT® 71260) And ANY ONE of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)
Resected ampullary cancer	Every 3 months for 2 years, then every 6 months for up to 5 years: • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) • CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)
Measurable metastatic disease on maintenance therapy or being monitored off therapy	Every 3 months for up to 5 years after completion of definitive treatment, then annually: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)

Evidence Discussion

Data on the role of surveillance in pancreatic cancer are limited, due to the poor prognosis and small numbers of individuals with long-term follow up. The NCCN recommendations for surveillance are based on consensus rather than data, and SEER-Medicare data shows no significant survival benefit for individuals who received regular surveillance scans/no improved outcome with earlier detection of recurrence.[1,23] The role of ongoing imaging in individuals with metastatic disease on maintenance or observation is also unclear. There is no clear data on length of time for maintenance

Proprietary Information of UnitedHealthcare.

therapy in those with metastatic disease, and treatment 'holidays' are often interjected in therapy. Outside of situations where there is a clear impact on management decisions, ASCO stated that imaging should be supplanted by clinical evaluation.[24] However, the NCCN offered several second and third-line treatment options. These guidelines provide some flexibility for individual-centricity and provider preference in this setting, allowing for CT Chest, Abdomen and Pelvis every 3 months for up to 5 years and then annually after completion of definitive treatment.[1] Specifically for individuals with resected ampullary cancer, NCCN recommended surveillance after adjuvant therapy every three to six months for two years, then every six to 12 months for up to five years. Imaging studies as well as history, physical exam, and tumor marker studies are recommended components of surveillance for these individuals.[25]

Hepatocellular Carcinoma (HCC) – General Considerations (ONC-14.1)

ON.GI.0014.1.A

v3.0.2026

- A biopsy is not always required for the diagnosis of Hepatocellular carcinoma (HCC). A dedicated triple-phase CT or MRI is medically necessary. MRI with contrast is the test of choice for the evaluation of liver masses. It offers soft tissue contrast resolution superior to CT as well as the possibility of using two different contrast agents, one of which if more blood flow based and the other which also is blood flow based and demonstrates hepatobiliary function (Eovist). Classical imaging findings include:
  - arterial phase hyper-enhancement
  - venous phase washout appearance
  - capsule appearance
  - threshold growth
- For individuals who are high-risk for developing HCC (cirrhosis, chronic Hepatitis B or current or prior HCC), if the liver lesion is >1cm with 2 classic enhancements on triple-phase CT or MRI, the diagnosis is confirmatory and biopsy is not needed.
- For lesions less than 1cm or with less than 2 classical enhancements or for any liver lesions in individuals who are not high-risk, a biopsy is needed for histological confirmation. PET/CT scan is considered not medically necessary for the diagnosis or staging of HCC.

Evidence Discussion

HCC does not necessarily require a biopsy for diagnosis as a triple phase CT or MRI can support the diagnosis in the absence of biopsy as these lesions are characterized by arterial hypervascularity and "wash out" on portal venous phases unlike the surrounding liver. For individuals who are high-risk for developing HCC (cirrhosis, chronic Hepatitis B or current or prior HCC), if the liver lesion is >1cm with 2 classic enhancements on triple-phase CT or MRI, the diagnosis is confirmatory and biopsy is not needed. For lesions less than 1cm or with less than 2 classical enhancements or for any liver lesions in individuals who are not high-risk, a biopsy may be needed for histological confirmation. Serum biomarkers such as AFP are not sensitive or specific enough to establish a diagnosis. PET/CT scan is not medically necessary for the diagnosis or staging of HCC due to limited sensitivity.[2,15]

Hepatocellular Carcinoma (HCC) – Initial Work-up/Staging (ONC-14.3)

ON.GI.0014.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
All individuals	• CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) And ONE of the following: • CT Abdomen with contrast (CPT® 74160) • CT Abdomen without and with contrast (CPT® 74170) • CT Abdomen and Pelvis with contrast (CPT® 74177) or without and with contrast (CPT® 74178) • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast • Bone scan (CPT® 78306) (for skeletal symptoms)
Inconclusive conventional imaging	• PET/CT (CPT® 78815)

Evidence Discussion

Initial imaging of hepatocellular carcinoma seeks to establish the tumor burden in the liver. CT or MRI imaging is preferred over the use of ultrasound. Additionally, common sites of metastases in individuals with hepatocellular carcinoma include the lungs, adrenal glands, peritoneum, and bone. Thus, initial work-up for all newly diagnosed individuals requires chest imaging. Bone scan completes this initial work-up by allowing dedicated imaging to identify potential bone metastases if suspected. PET/CT is a useful tool for evaluating inconclusive findings on the initial imaging studies due to its limited specificity but high sensitivity.[2,8]

Hepatocellular Carcinoma (HCC) – Restaging/Recurrence (ONC-14.4)

ON.GI.0014.4.A
v3.0.2026

Indication	Medically Necessary Imaging Study
ONE of the following: • After initial therapy • For suspected recurrence or new liver lesions • Individuals receiving systemic therapy (every 2 cycles)	• CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) And ONE of the following: • CT Abdomen with contrast (CPT® 74160) • CT Abdomen without and with contrast (CPT® 74170) • CT Abdomen and Pelvis with contrast (CPT® 74177) or CT Abdomen and Pelvis without and with contrast (CPT® 74178) • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast
Inconclusive conventional imaging	• PET/CT (CPT® 78815)
Hepatocellular Carcinoma treated with local therapy (ablation, embolization)	See: **Liver Metastases (ONC-31.2)** for imaging studies prior to and post-procedure
Hepatocellular Carcinoma awaiting liver transplant	See: **Liver Transplant, Pre-Transplant (AB-42.1)** in the Abdomen Imaging Guidelines

Evidence Discussion

To assess response after treatment, dedicated imaging of the chest, abdomen, and pelvis are medically necessary. NCCN stated, "CT of the chest and CT or MRI of the abdomen and pelvis are the preferred modalities as they reliably assess intranodular arterial vascularity, a key feature of residual or recurrent tumor".[2] Thus, these studies are medically necessary for suspected recurrence or new liver lesions. PET/CT remains a useful tool for evaluation of inconclusive conventional studies due to its limited sensitivity but high specificity.[2] For individuals undergoing liver embolization, CTA Abdomen is medically necessary immediately prior to this procedure. In addition, either

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

MRI or CT of the Abdomen with and without contrast is medically necessary immediately prior and 1 month post-ablation.[2,8] ONC-31.2 provides a broader description of additional appropriate studies prior to and after embolization for liver metastases.

Click Here to Return to the Main TOC

Hepatocellular Carcinoma (HCC) – Surveillance/Follow-up (ONC-14.5)

ON.GI.0014.5.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Hepatocellular Carcinoma: • Treated with surgical resection • Treated with embolization • Being monitored off therapy	Every 3 months for 2 years, then every 6 months until year 5: • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) And ONE of the following: • CT Abdomen with contrast (CPT® 74160) • CT Abdomen without and with contrast (CPT® 74170) • CT Abdomen and Pelvis with contrast (CPT® 74177) or without and with contrast (CPT® 74178) • MRI Abdomen (CPT® 74183) and Pelvis (CPT® 72197) without and with contrast
Hepatocellular Carcinoma treated with liver transplant	• See: **Liver Transplant, Post-transplant Imaging (AB-42.3)** in the Abdomen Imaging Guidelines

Evidence Discussion

For individuals treated with surgical resection, embolization, or being monitored off therapy, CT Chest with or without contrast is medically necessary every 3 months for 2 years then every 6 months until year 5 as well as one of the following: CT Abdomen with or with/without contrast, CT Abdomen/Pelvis with or with/without contrast or MRI Abdomen/Pelvis with and without contrast. Multiphasic cross-sectional imaging with CT or MRI is preferred due to its reliability in assessing arterial vascularity, which is associated with increased risk of recurrence following treatment.[2,9,10] HCC treated with transplant is addressed in AB-42.3, Liver Transplant and Post-Transplant Imaging.

Gallbladder and Biliary Tumors – Initial Work-up/Staging (ONC-14.6)

ON.GI.0014.6.A
v3.0.2026

Indication	Medically Necessary Imaging Study
All individuals	• CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) And ONE of the following: • CT Abdomen with contrast (CPT® 74160) • CT Abdomen without and with contrast (CPT® 74170) • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast • MRCP with 3D rendering (CPT® 74183 and CPT® 76376 or CPT® 76377)
Inconclusive liver findings on CT (if MRI not already performed)	MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast
Inconclusive findings on MRI Abdomen	• PET/CT (CPT® 78815)

Evidence Discussion

High-quality contrast-enhanced cross-sectional imaging (CT and/or MRI) of the chest, abdomen, and pelvis is medically necessary to evaluate tumor penetration through the wall of the gallbladder and the presence of nodal and distant metastases, and to detect the extent of direct tumor invasion of other organs/biliary system or major vascular invasion. PET/CT is a useful tool for inconclusive findings on CT/MRI, with downsides including false-positives related to inflammation of the gallbladder.[3,11,12]

Click Here to Return to the Main TOC

Gallbladder and Biliary Tumors – Restaging/Recurrence (ONC-14.7)

ON.GI.0014.7.A
v3.0.2026

Indication	Medically Necessary Imaging Study
ANY of the following: • After initial therapy • For suspected recurrence or new liver lesions • Individuals receiving systemic chemotherapy (every 2 cycles)	• CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) And ONE of the following: • CT Abdomen with contrast (CPT® 74160) • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast
Inconclusive liver findings on CT (if MRI not already performed for restaging)	• MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast
Inconclusive findings on MRI Abdomen	• PET/CT (CPT® 78815)

Evidence Discussion

CT Chest with or without contrast plus one of the following is medically necessary: CT Abdomen with or with/without contrast, CT Abdomen/Pelvis with contrast and MRI Abdomen/Pelvis with and without contrast. High-quality contrast-enhanced cross-sectional imaging (CT and/or MRI) of the chest, abdomen, and pelvis is recommended to evaluate tumor penetration through the wall of the gallbladder and the presence of nodal and distant metastases, and to detect the extent of direct tumor invasion of other organs/biliary system or major vascular invasion. PET/CT is medically necessary for inconclusive findings on CT/MRI, keeping in mind false positives related to an inflamed gallbladder are problematic.[3,11,12]

Click Here to Return to the Main TOC

Gallbladder and Biliary Tumors – Surveillance/Follow-up (ONC-14.8)

ON.GI.0014.8.A
v3.0.2026

Indication	Medically Necessary Imaging Study
All individuals	Every 3 months for 2 years, and then every 6 months up to year 5: • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) And ONE of the following: • CT Abdomen with contrast (CPT® 74160) • CT Abdomen without and with contrast (CPT® 74170) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen and Pelvis without and with contrast (CPT® 74178) • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast
Biliary carcinoma treated with liver transplant	See: **Liver Transplant, Post-transplant Imaging (AB-42.3)** in the Abdomen Imaging Guidelines

Evidence Discussion

NCCN stated "there are no data to support a specific surveillance schedule following resection of gallbladder cancer".[3] However, NCCN did suggest consideration of imaging studies every three to six months for two years, and then every six to twelve months for up to five years. Recurrence typically occurs within two years.[3] Thus, this guideline allows for all individuals to receive imaging based upon that schedule. Biliary cancer treated with liver transplant would follow AB-42.3, Liver Transplant, Post-transplant Imaging.

Gastric Cancer – Initial Work-up/Staging (ONC-14.9)

ON.GI.0014.9.A
v3.0.2026

Indication	Medically Necessary Imaging Study
All individuals	• CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177)
Gastric cancer ≥T2 or higher with no metastatic disease by conventional imaging	• PET/CT (CPT® 78815)

Evidence Discussion

All individuals should get CT Chest/Abdomen/Pelvis with contrast. For T2 or higher stage disease with no metastatic disease by CT, PET/CT is medically necessary to complete staging. FDG-PET alone is not an adequate diagnostic procedure in the detection and preoperative staging of gastric cancer, but can be helpful when used in conjunction with CT.[1,13,14]

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Gastric Cancer – Restaging/Recurrence (ONC-14.10)

ON.GI.0014.10.A
v3.0.2026

Indication	Medically Necessary Imaging Study
• After completion of primary therapy (to include chemotherapy and/or chemoradiotherapy), prior to surgery • After completion of chemoradiation therapy with definitive intent (i.e., no metastatic disease and no anticipated resection surgery) • For suspected recurrence	• CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177)
Monitoring response to chemotherapy (every 2 cycles, ~every 6-8 weeks) for: • Unresected primary disease • Metastatic disease	• CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Chest with contrast (CPT® 71260)
New liver lesion(s) and primary site controlled	• CT Abdomen without and with contrast (CPT® 74170) or MRI Abdomen without and with contrast (CPT® 74183)
EITHER of the following: • Inconclusive findings on conventional imaging • Restaging of individuals with unresectable disease who cannot undergo CT with contrast due to renal insufficiency or contrast allergy	• PET/CT (CPT® 78815)

Evidence Discussion

CT Chest/Abdomen/Pelvis is medically necessary after initial therapy for presumed resectable disease, post curative chemoradiation (no surgery) and for suspected recurrence. Monitoring chemotherapy response should include CT Abdomen/Pelvis and include CT Chest for known disease, new/worsening pulmonary symptoms or abnormal chest x-ray. PET/CT is medically necessary with inconclusive findings on

Proprietary Information of UnitedHealthcare.

Gastric Cancer – Surveillance/Follow-up (ONC-14.11)

ON.GI.0014.11.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Stage I (treated with resection alone)	• No routine imaging unless clinical signs/ symptoms of recurrence
ANY of the following: • Stage I treated with systemic therapy • Stages II-III • Stage IV - Metastatic disease with no measurable disease post definitive treatment	Every 6 months for 2 years, and then annually for 3 more years: • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) and CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ In individuals who cannot undergo CT with contrast due to renal insufficiency or contrast allergy, MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) are the medically necessary substitute.
Measurable metastatic disease on maintenance therapy or being monitored off therapy	Every 3 months for up to 5 years after completion of active treatment: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177)

Evidence Discussion

Stage I treated with resection alone does not require routine imaging in the absence of signs/symptoms of recurrence. Stage I treated with systemic therapy, Stages II-III and Stage IV s/p definitive treatment of all measurable disease or being observed off therapy should undergo CT Chest/Abdomen/Pelvis every 6 months for 2 years then annually up to 5 years. Measurable metastatic disease on maintenance therapy or being monitored off therapy should undergo CT Chest/Abdomen/Pelvis every 3 months for up to 5 years after completion of active treatment.[1]

General Considerations (ONC-15.1)

ON.NA.0015.1.A
v3.0.2026

This guideline includes low-grade or well-differentiated carcinoid and endocrine tumors of the lung, thymus, pancreas, gastrointestinal tract, or unknown primary site; including insulinoma, glucagonoma, VIPoma, gastrinoma, somatostatinoma, and others, as well as catecholamine-secreting tumors of the adrenal gland such as pheochromocytoma, paraganglioma, adrenocortical carcinoma, and others.

- For poorly-differentiated or high-grade small cell or large cell neuroendocrine tumors arising outside the lung or from an unknown primary site, see: **Extrathoracic Small Cell and Large Cell Neuroendocrine Tumors (ONC-31.8)**.
- For poorly-differentiated or high-grade neuroendocrine tumors of the lung, see: **Small Cell Lung Cancer (ONC-7)**.
- Neuroblastoma, ganglioneuroblastoma, and ganglioneuroma occurring in adults should be imaged according to **Neuroblastoma (PEDONC-6)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
- Many are associated with Multiple Endocrine Neoplasia (MEN) familial syndromes.
  – See: **Multiple Endocrine Neoplasias (MEN) (PEDONC-2.8)** in the Pediatric and Special Populations Oncology Imaging Guidelines for screening recommendations.
- Somatostatin receptor (SSR) based imaging is more sensitive and specific for evaluation of well-differentiated neuroendocrine tumors and may be performed using ^{111}In DTPA Octreotide scintigraphy or PET/CT scan with SSR radiotracers (such as ^{68}Ga–DOTATATE, ^{68}Ga-DOTATOC, or ^{64}Cu-DOTATATE). This study is not part of evaluation of poorly-differentiated or high-grade neuroendocrine tumors, which are imaged according to: **Extrathoracic Small Cell and Large Cell Neuroendocrine Tumors (ONC-31.8)**.
- If dotatate PET/CT is medically necessary but not available, octreotide scan (any one of the following planar imaging codes: CPT® 78801, 78802, 78804 **AND** any one of the following SPECT/SPECT-CT codes: CPT® 78803, 78830, 78831, 78832) may be substituted for dotatate PET.

Evidence Discussion

This guideline includes low-grade or well-differentiated (Grade 1, 2, or 3; Ki-67 >20% and <55%) carcinoid and endocrine tumors of the lung, thymus, pancreas, gastrointestinal tract, or unknown primary site; including insulinoma, glucagonoma, VIPoma, gastrinoma, somatostatinoma, and others, as well as catecholamine-secreting tumors of the adrenal gland such as pheochromocytoma, paraganglioma, adrenocortical carcinoma, and others. These tumors are particularly sensitive and

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

specific to somatostatin receptor (SSR) based imaging (nearly 80% express SSR on the cell surface) while poorly differentiated or high-grade tumors typically are not, with imaging recommendations being addressed in separate guidelines.[1,9]

Gastrointestinal/Pancreatic Neuroendocrine Cancers – Suspected/ Diagnosis (ONC-15.2)

ON.NA.0015.2.A
v3.0.2026

Indication	Medically Necessary Imaging Study
• Systemic symptoms strongly suggestive of functioning neuroendocrine tumor • Suspicious findings on other imaging studies • Unexplained elevation in ANY of the following: ◦ Chromogranin A ◦ 5HIAA ◦ Insulin ◦ VIP ◦ Glucagon ◦ Gastrin ◦ Substance P ◦ Serotonin ◦ Somatostatin	ANY of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) or without and with contrast (CPT® 74178) **OR** MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) • CT with contrast or MRI without and with contrast of any other symptomatic body areas
• Continued suspicion with negative/ inconclusive CT or MRI	ONE of the following: • PET/CT (CPT® 78815) or PET/MRI (CPT® 78812 and CPT® 76498) with any ONE of the following SSR radiotracers: ◦ ^{68}Ga-DOTATATE ◦ ^{68}Ga-DOTATOC ◦ ^{64}Cu-DOTATATE

Evidence Discussion

Neuroendocrine tumors (NETs) arise from cells of the endocrine system that can be found throughout the body. They can occur sporadically or arise in the context

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

of an inherited genetic syndrome. Presentation is usually attributable to hormonal hypersecretion (functional tumors) that can include flushing/diarrhea/wheezing (Carcinoid syndrome), hypertension, and hypoglycemia versus being found incidentally on various imaging studies. If these symptoms/signs are suspicious for a NET, appropriate serologic/urinary workup may include chromogranin A, 5HIAA, insulin, VIP, glucagon, gastrin, substance P, serotonin and somatostatin. If these markers are elevated, CT chest with or without contrast as well as CT or MRI of abdomen/pelvis/any other symptomatic body area is medically necessary. CT is best for detection of primary small bowel lesions and lymphadenopathy while MRI is preferred for pancreatic NETs and detecting hepatic metastases. If these imaging studies are negative/inconclusive, SSR based imaging with either Octreotide scan or Dotatate/Dotatoc (Gallium-68, Copper-64) is medically necessary (SSR PET/CT). All three of these functional imaging modalities are FDA approved and can be performed in individuals on somatostatin analog therapy and are considered to be superior to Octreotide scan. FDG-based PET/CT has limited use, as the majority of NETs are metabolically inactive and fail to take up the tracer well.[1,9,10,11]

v3.0.2026

- For undifferentiated neuroendocrine tumors, see: **Extrathoracic Small Cell and Large Cell Neuroendocrine Tumors ONC-31.8**

Indication	Medically Necessary Imaging Study
ANY of the following: • Well-differentiated Grade 1-2 tumors ◦ Jejunal ◦ Ileal ◦ Colon ◦ Type 3 Gastric ◦ Neuroendocrine tumors of unknown primary • Well-differentiated Grade 3 tumors	If not already done, ANY or ALL of the following: • PET/CT (CPT® 78815) or PET/MRI (CPT® 78812 and CPT® 76498) with any ONE of the following SSR radiotracers: ◦ ^{68}Ga-DOTATATE ◦ ^{68}Ga-DOTATOC ◦ ^{64}Cu-DOTATATE • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) • And ONE of the following: ◦ CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ CT Abdomen and Pelvis without and with contrast (CPT® 74178) ◦ MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
All other GI or pancreatic neuroendocrine tumors, including, but not limited to, duodenal, appendix (>2cm or any tumor size with incomplete resection or positive nodes/ margins), rectal (T2-T4 or positive nodes), and pancreas (nonfunctional, gastrinoma, insulinoma, glucagonoma, VIPoma)	If not already done: • CT Abdomen and Pelvis with contrast (CPT® 74177) or without and with contrast (CPT® 74178) OR MRI Abdomen (CPT® 74183) and Pelvis (CPT® 72197) without and with contrast • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250)
Locally advanced or metastatic disease (any location or histology) not amenable to curative intent resection to assess candidacy for treatment with somatostatin analogues	If not already done, ANY or ALL of the following: • PET/CT (CPT® 78815) or PET/MRI (CPT® 78812 and CPT® 76498) with any ONE of the following SSR radiotracers: ◦ ^{68}Ga-DOTATATE ◦ ^{68}Ga-DOTATOC ◦ ^{64}Cu-DOTATATE • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) • And ONE of the following: ◦ CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ CT Abdomen and Pelvis without and with contrast (CPT® 74178) ◦ MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast
Inconclusive CT or MRI scans	ONE of the following: • PET/CT (CPT® 78815) or PET/MRI (CPT® 78812 and CPT® 76498) with any ONE of the following SSR radiotracers: ◦ ^{68}Ga-DOTATATE ◦ ^{68}Ga-DOTATOC ◦ ^{64}Cu-DOTATATE

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
ANY of the following: • Markers fail to normalize after complete resection AND CT/MRI and somatostatin-receptor based study are negative • Biopsy-proven neuroendocrine tumor of unknown primary site AND CT/ MRI and somatostatin-receptor based study are negative	• FDG-PET/CT (CPT® 78815)

Evidence Discussion

For initial evaluation of all neuroendocrine tumors, the National Comprehensive Cancer Network (NCCN) recommended that cross-sectional imaging be performed of the primary site of disease utilizing either CT or MRI. Imaging with chest CT is also an NCCN recommended consideration. For certain disease types including well-differentiated grade 1-2 tumors, including neuroendocrine tumors of the jejunum, ileum, duodenum, and colon, as well as gastric type 3 and neuroendocrine tumors of unknown primary, and grade 3 well-differentiated tumors, the NCCN recommends that a PET/CT or PET/MRI utilizing SSR radiotracers be performed in addition to diagnostic CT or MRI imaging. Brain imaging is not medically necessary for well-differentiated NET without signs and symptoms of neurologic involvement. The NCCN states octreotide scans are "much less sensitive for defining SSTR-positive disease than PET". Thus, these guidelines reserve octreotide scans as a problem-solving tool if PET is inconclusive or not available.[1,10,11]

Gastrointestinal/Pancreatic Neuroendocrine Cancers – Restaging/ Recurrence (ONC-15.4)

ON.NA.0015.4.A
v3.0.2026

Indication	Medically Necessary Imaging Study
All after surgical resection	• See: **Gastrointestinal/Pancreatic Neuroendocrine Cancers – Surveillance (ONC-15.5)**
Unresectable/metastatic disease on treatment with somatostatin analogues	• CT or MRI of involved body area no more frequently than every 3 months
Unresectable/metastatic disease on treatment with chemotherapy or PRRT (i.e., Lutathera)	• CT or MRI of involved body area every 2 cycles (6 to 8 weeks)
Suspected recurrence	• PET/CT (CPT® 78815) or PET/MRI (CPT® 78812 and CPT® 76498) with any ONE of the following SSR radiotracers: ◦ ^{68}Ga-DOTATATE ◦ ^{68}Ga-DOTATOC ◦ ^{64}Cu-DOTATATE AND • CT Chest without contrast (CPT® 71250) or CT Chest with contrast (CPT® 71260) And ONE of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen and Pelvis without and with contrast (CPT® 74178) • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Continued suspicion for recurrence with negative or inconclusive CT or MRI, and PET not available	• Octreotide scan: ◦ Any one of the following planar imaging codes - CPT® 78801, 78802, or 78804 ◦ Any one of the following SPECT/SPECT-CT codes - CPT® 78803, 78830, 78831, 78832 - may be approved as an add-on
To assess candidacy for peptide receptor radionuclide therapy (PRRT) with Lutetium ^{177}Lu-dotatate	• PET/CT (CPT® 78815) or PET/MRI (CPT® 78812 and CPT® 76498) with any ONE of the following SSR radiotracers: ◦ ^{68}Ga-DOTATATE ◦ ^{68}Ga-DOTATOC ◦ ^{64}Cu-DOTATATE

Evidence Discussion

NCCN recommended that for any suspected recurrence of disease, PET/CT or PET/MRI be performed in addition to systemic diagnostic imaging. For individuals with unresectable/metastatic disease, NCCN stated that "anatomic imaging should generally be performed every 12 weeks-12 months based on clinical or pathologic signs of aggressiveness". Thus, CT imaging of involved body area is recommended every 3 months if on somatostatin therapy versus every 2 cycles (6-8 weeks) if on chemotherapy. To assess for candidacy for peptide receptor radionuclide therapy (PRRT) with Lutetium Lu-177 dotatate (Lutathera), any of the 3 SSR PET/CT or PET/MRI options are medically necessary. The NCCN stated octreotide scans are "much less sensitive for defining SSTR-positive disease than PET". Thus, these guidelines reserve octreotide scans as a problem-solving tool if PET is inconclusive or not available.[1]

Gastrointestinal/Pancreatic Neuroendocrine Cancers – Surveillance (ONC-15.5)

ON.NA.0015.5.A
v3.0.2026

Indication	Medically Necessary Imaging Study
ANY of the following: • Appendix carcinoid <1cm, completely resected • Rectal carcinoid <1cm, completely resected • Gastric carcinoid treated with complete endoscopic resection	• Advanced imaging is not medically necessary for surveillance
Rectal carcinoid 1-2cm, completely resected	• MRI Pelvis without and with contrast (CPT® 72197) at 6 and 12 months post resection. No further routine surveillance.
All other GI neuroendocrine tumors (stomach, large and small intestine)	• CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast once at 3 to 12 months post-operatively and every 12-24 months up to year 10
Unresected GI neuroendocrine tumors being monitored with observation alone	• CT Abdomen with contrast (CPT® 74160) once at 3 to 12 months from initial diagnosis, then every 3 months for 1 year, then every 6 months in year 2, and then annually up to year 10
Pancreatic neuroendocrine tumors	• CT Abdomen with contrast (CPT® 74160) once at 3 to 12 months post-operatively then annually up to year 10
Unresected pancreatic neuroendocrine tumors being monitored with observation alone	• CT Abdomen with contrast (CPT® 74160) once at 3 to 12 months from initial diagnosis then annually up to year 10

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Measurable metastatic disease on maintenance treatment or off therapy	• CT of involved body area no more frequently than every 3 months

Evidence Discussion

In the absence of signs/symptoms of recurrence, advanced imaging is not medically necessary for completely resected appendiceal carcinoid <1cm, completely resected rectal carcinoid <1cm, and gastric carcinoid treated with complete endoscopic resection due to their excellent prognosis and low risk of recurrence.[6,13] For completely resected rectal carcinoid 1-2cm, MRI pelvis with and without contrast at 6 and 12 months post-resection is medically necessary, and if clear, no further imaging. Due to the indolent nature of NETs, long term follow-up is recommended. For all other GI NETs, CT or MRI abdomen/pelvis once 3-12 months post-operatively and then every 12-24 months for 10 years is supported by NCCN. Unresected GI NETs on observation should undergo CT abdomen with contrast once at 3-12 months from initial diagnosis then annually up to year 10. Resected pancreatic NETs should undergo CT abdomen with contrast once at 3-12 months post-operatively then annually up to year 10. Unresected pancreatic NETs should undergo CT Abdomen with contrast once at 3-12 months from initial diagnosis then annually up to year 10. For individuals with measurable metastatic disease on maintenance or off therapy, CT of involved body area is medically necessary no more frequently than every 3 months. After 10 years, surveillance should be as clinically indicated.[1]

Bronchopulmonary or Thymic Carcinoid – Initial Staging (ONC-15.6)

ON.NA.0015.6.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Initial diagnosis	If not already done: • CT Chest with contrast (CPT® 71260) • CT Abdomen with contrast (CPT® 74160) or without and with contrast (CPT® 74170) or MRI Abdomen (CPT® 74183) without and with contrast
Inconclusive CT or MRI scans	ONE of the following: • PET/CT (CPT® 78815) or PET/MRI (CPT® 78812 and CPT® 76498) with any ONE of the following SSR radiotracers: ◦ ^{68}Ga-DOTATATE ◦ ^{68}Ga-DOTATOC ◦ ^{64}Cu-DOTATATE
ANY of the following: • Markers fail to normalize after complete resection AND CT/MRI and somatostatin-receptor based study are negative • Biopsy-proven neuroendocrine tumor of unknown primary site AND CT/MRI and somatostatin-receptor based study are negative	• FDG-PET/CT (CPT® 78815) OR PET/MRI (CPT® 78812 and CPT® 76498)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Locally advanced or metastatic disease (any location or histology) not amenable to curative intent resection to assess candidacy for treatment with somatostatin analogues	If not already done, ANY or ALL of the following: • PET/CT (CPT® 78815) or PET/MRI (CPT® 788123 and CPT® 76498) with any ONE of the following SSR radiotracers: ◦ ^{68}Ga-DOTATATE ◦ ^{68}Ga-DOTATOC ◦ ^{64}Cu-DOTATATE • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) • And ONE of the following: ◦ CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ CT Abdomen and Pelvis without and with contrast (CPT® 74178) ◦ MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast

Evidence Discussion

More than 80% of lung carcinoids are diagnosed at Stage I or II with the most common sites of metastases being liver, bone, and lung.[14] Most thymic carcinoids are diagnosed at Stage III or IV with the most common sites of metastases being pleura, pericardium, bone, lung, and liver. Medically necessary initial imaging includes CT Chest with contrast and CT or MRI of the abdomen. Imaging of the brain, pelvis or osseous structures is based on signs/symptoms of disease. If the CT/MRI is inconclusive, Octreotide scan or SSR-based PET is medically necessary. In the setting where markers fail to normalize after surgery AND CT/MRI and SSR based study are negative OR there is biopsy proven NET of unknown origin AND CT/MRI and SSR based study are negative, FDG-based PET is medically necessary for the concern of a higher-grade NET being present.[10,11]

Bronchopulmonary or Thymic Carcinoid – Surveillance (ONC-15.8)

ON.NA.0015.8.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Carcinoid tumors of lung or thymus	• CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) and CT Abdomen with contrast (CPT® 74160) once at 3 to 12 months post-resection and then annually up to year 10
Unresected primary tumors being monitored with observation alone	• CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) and CT Abdomen with contrast (CPT® 74160) once at 3 to 12 months from initial diagnosis then annually up to year 10
Asymptomatic lung or thymus distant metastasis on observation alone	Every 3 months for 1 year, and then every 6 months: • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) • CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast
Measurable metastatic disease on maintenance treatment or off therapy	• CT Chest with contrast (CPT® 71260) • CT of involved body area no more frequently than every 3 months

Evidence Discussion

For carcinoid tumors of the lung or thymus, prognosis varies. In typical lung carcinoid, 5-year and 10-year overall survival (OS) is approximately 81% to 96%, and 74% to 91%, respectively, for both node negative and node positive disease. With atypical histology, 5-year OS is 82% to 90% in node negative disease and 58 to 71% in node positive disease. Thymic carcinoid 5-year OS is <50%. Due to lack of long-term follow-up imaging studies, it is recommended to minimize risk of radiation exposure using CT or MRI.[14] In individuals with resected disease, CT Chest 3-12 months post resection and then annually for up to 3 years then every 2 years up to year 10 is medically necessary. Unresected primary tumors on observation follow a similar schedule with CT Chest 3-12 months from initial diagnosis and then annually for up to 3 years then every 2 years up to year 10. Measurable metastatic disease on maintenance therapy or observation

Adrenal Tumors – Suspected/Diagnosis (ONC-15.9)

ON.NA.0015.9.A

v3.0.2026

- See: **Adrenal Cortical Lesions (AB-16.1)** in the Abdomen Imaging Guidelines for evaluation of indeterminate adrenal masses.
- Adrenal tumors that involve the adrenal medulla or neural crest tissue outside the adrenal gland include pheochromocytoma, paraganglioma, and paraganglioneuroma.
  - These tumors are imaged according to sections **ONC-15.10 through ONC-15.12**.
  - Malignant adrenal tumors that involve the adrenal cortex are addressed in **Adrenocortical Carcinoma (ONC-15.13).**
- Adrenocortical carcinoma is imaged according to **Adrenocortical Carcinoma (ONC-15.13)**.
- If concern for genetic predisposition syndrome such as MEN, neurofibromatosis, or Von Hippel-Lindau disease, see screening recommendations in **Screening Imaging and Cancer Predisposition Syndromes (PEDONC-2)** in the Pediatric and Special Populations Oncology Imaging Guidelines.

Adrenal Tumors – Initial Work-up/Staging (ONC-15.10)

ON.NA.0015.10.A
v3.0.2026

- This guideline can be applied to **any primary site** (including beyond adrenal gland) for pheochromocytoma, paraganglioma, or paraganglioneuroma.

Indication	Medically Necessary Imaging Study
For ANY of the following: • Pheochromocytoma • Paraganglioma • Paraganglioneuroma	If not already done: • CT Chest without (CPT® 71250) or CT Chest with contrast (CPT® 71260) And ONE of the following (if not already done): • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen and Pelvis without and with contrast (CPT® 74178) • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast • CT with contrast or MRI without and with contrast of primary site (i.e., neck) and any other symptomatic body areas
Hypercortisolemia with ANY of the following: • Tumor greater than 4cm • Inhomogeneous • Irregular margins • Local invasion • Other malignant imaging characteristics	ANY or ALL of the following: • FDG PET/CT (CPT® 78815) • CT Abdomen with contrast (CPT® 74160) or CT Abdomen without and with contrast (CPT® 74170) or MRI Abdomen without and with contrast (CPT® 74183)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Continued suspicion with negative/ inconclusive CT or MRI	ONE of the following: • PET/CT (CPT® 78815) or PET/MRI (CPT® 78812 and CPT® 76498) with any ONE of the following SSR radiotracers: ◦ ^{68}Ga-DOTATATE ◦ ^{68}Ga-DOTATOC ◦ ^{64}Cu-DOTATATE
All above studies done and negative/ inconclusive	• FDG PET/CT scan (CPT® 78815)

Evidence Discussion

Radiologic evaluation of adrenal tumors should follow biochemical conformation of the diagnosis of pheochromocytoma and paraganglioglioma. Ninety-five percent of this group of tumors occur in the abdomen and pelvis. Paragangliomas account for 15% of this group of tumors. The initial work-up/staging of this group of tumors includes CT Chest (with contrast or without contrast), as approximately 10% of paragangliomas are found in the chest, and pheochromocytoma has a potential to metastasize to chest. CT imaging with or without and with contrast or MRI imaging without and with contrast of the abdomen, pelvis and any other symptomatic body areas are medically necessary for initial staging. Hypercortisolemia can be caused by benign and malignant tumors. NCCN stated, "Malignancy should be suspected if the tumor is larger than 4 centimeters or is inhomogeneous with irregular margins and/or has local invasion and other malignant imaging characteristics" and went on to recommend imaging with PET/CT, CT Chest, and CT or MRI abdominal imaging.[1]

Functional imaging is a valuable problem-solving tool when there is continued suspicion for this group of tumors with inconclusive or negative findings on CT/ MRI. ^{123}I/ ^{131}I-MIBG sensitivity is higher for detecting pheochromocytoma than for detecting paraganglioma, at 88% and 67%, respectively. Another approach to functional imaging utilizes ^{68}Ga-DOTA-somatostatin analogs including DOTATOC, DOTANOC, and DOTATATE (SSR-PET/CT). In meta-analyses, the sensitivity of 68Ga-DOTA-somatostatin analogs (93%) is superior to ^{18}F-FDG (74%), and ^{123}I/ ^{131}I-MIBG (38%). Imaging with ^{111}In-pentetreotide (octreotide) (24%) is less sensitive that imaging with ^{68}Ga-DOTA-somatostatin analogs. Of note, functional imaging using ^{18}F-FDG PET/CT can be useful for evaluation in the scenario that CT/MRI and other functional imaging studies are negative/inconclusive.[1,15-18]

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Adrenal Tumors – Restaging/Recurrence (ONC-15.11)

ON.NA.0015.11.A
v3.0.2026

- This guideline can be applied to **any primary site** (including beyond adrenal gland) for pheochromocytoma, paraganglioma, or paraganglioneuroma.

Indication	Medically Necessary Imaging Study
If surgery is primary therapy	See: **ONC-15.12** for surveillance recommendations
Recurrence, progression of symptoms, or elevation of tumor markers	• CT Chest without contrast (CPT® 71250) or CT Chest with contrast (CPT® 71260) • CT with contrast of primary site (i.e., neck) and involved areas And ONE of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen and Pelvis without and with contrast (CPT® 74178) • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast
Continued suspicion for recurrence with negative or inconclusive CT or MRI	ONE of the following: • PET/CT (CPT® 78815) or PET/MRI (CPT® 78812 and CPT® 76498) with any ONE of the following SSR radiotracers: ◦ ^{68}Ga-DOTATATE ◦ ^{68}Ga-DOTATOC ◦ ^{64}Cu-DOTATATE
To assess candidacy for peptide receptor radionuclide therapy (PRRT) with Lutetium ^{177}Lu-dotatate	• PET/CT (CPT® 78815) or PET/MRI (CPT® 78812 and CPT® 76498) with any ONE of the following SSR radiotracers: ◦ ^{68}Ga-DOTATATE ◦ ^{68}Ga-DOTATOC ◦ ^{64}CU-DOTATATE

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
For ANY of the following: • All above studies done and negative/ inconclusive • Hypercortisolemia with inconclusive findings on CT • Pheochromocytoma bone-dominant disease • Paraganglioma bone-dominant disease	• FDG-PET/CT scan (CPT® 78815)

Evidence Discussion

In individuals who underwent surgery for resection of localized disease, CT Abdomen with contrast is medically necessary within the first year post-resection. Follow-up imaging is based on surveillance recommendations noted in Adrenal Tumors – Surveillance (ONC 15.12). In individuals who develop recurrence, progression of symptoms or elevation of tumor markers, the extent of disease must be determined with CT/MRI imaging. CT chest (with contrast or without contrast), CT imaging with or without and with contrast, or MRI imaging without and with contrast of the abdomen, pelvis and any any other symptomatic body areas are medically necessary. Functional imaging with ^{111}In-pentetreotide (octreotide scan) or ^{68}Ga-DOTA-somatostatin analog PET is a valuable problem solving tool when there is continued suspicion of recurrence with inconclusive or negative findings on CT/MRI. Further evaluation using ^{18}F-FDG PET/CT can be useful for evaluation in the scenario that CT/MRI and other functional imaging studies are negative/inconclusive. ^{18}F-FDG PET/CT is also supported by NCCN for the evaluation of hypercortisolemia with inconclusive findings on CT, pheochromocytoma bone-dominant disease, and paraganglioma bone-dominant disease.[1,15-18]

Adrenal Tumors – Surveillance (ONC-15.12)

ON.NA.0015.12.A
v3.0.2026

- This guideline can be applied to **any primary site** (including beyond adrenal gland) for pheochromocytoma, paraganglioma, paraganglioneuroma, or hypercortisolemia.

Indication	Medically Necessary Imaging Study
All individuals	Once within 3-12 months post resection and then annually for 10 years: • CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250) • CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen and Pelvis without and with contrast (CPT® 74183 and 72197) • CT with contrast of primary site (i.e., neck) and other involved body areas
Measurable metastatic disease being observed off therapy or on maintenance treatment	• CT of involved body area no more frequently than every 3 months for up to 5 years after completion of definitive therapy and annually thereafter

Evidence Discussion

In individuals who had resectable disease, CT imaging of the chest and either CT or MR imaging of the abdomen, pelvis, and any other previously involved body areas are medically necessary once within 3-12 months post-resection then annually for 10 years. Individuals with measurable metastatic disease being observed off therapy or on maintenance therapy are at greater risk for recurrence. In addition to the imaging schedule noted above, imaging of the involved body area is medically necessary with greater frequency (3 months) for up to 5 years followed by annual imaging.[1,15-18]

Adrenocortical Carcinoma (ONC-15.13)

ON.NA.0015.13.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Initial Staging	• FDG PET/CT (CPT® 78815) • CT Chest without (CPT® 71250) or CT Chest with contrast (CPT® 71260) And ONE of the following (if not already done): • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen and Pelvis without and with contrast (CPT® 74178) • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast
Suspected recurrence	• CT Chest without (CPT® 71250) or CT Chest with contrast (CPT® 71260) And ONE of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen and Pelvis without and with contrast (CPT® 74178) • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast
• Inconclusive findings on conventional imaging	• FDG PET/CT (CPT® 78815)
Surveillance after complete response to definitive treatment	Annually for 5 years: • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) • CT Abdomen with contrast (CPT® 74160) or MRI Abdomen (CPT® 74183) without and with contrast • CT of other involved body areas with contrast

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Measurable metastatic disease on maintenance therapy or being monitored off therapy	Every 3 months for up to 5 years after completion of definitive therapy: • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) • CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast • CT with contrast of other involved body areas

Evidence Discussion

Adrenocortical carcinoma (ACC) is a rare, aggressive tumor arising from the adrenal cortex. Most cases of ACC are sporadic; however, ACC has been described as a component of hereditary cancer syndromes that include Li-Fraumeni syndrome, Beckwith-Weidemann syndrome and multiple endocrine neoplasia type 1 (MEN1). Recommended imaging guidelines for screening of individuals with these syndromes are summarized in Screening Imaging in Cancer Predisposition Syndromes (PEDONC-2). ACCs that secrete excess adrenal hormones are classified as functional tumors and occur in 15-30% of cases in adults. Those individuals with functional tumors present with Cushing's syndrome and/or virilization. The majority of adults with non-functioning ACCs present symptomatically with abdominal pain or flank pain; however, these tumors may present asymptomatically as a large palpable intra-abdominal mass or incidentally as a small adrenal mass. Approximately 30% of ACCs present with metastatic disease in lymph nodes, lung, liver, and bone. ACCs may also present with invasion of adjacent structures and with venous extension.

CT and MRI cross-sectional imaging are the standard imaging modalities used for the evaluation of ACC. Due to the measurable risk for widely metastatic disease at initial presentation, cross-section imaging of the chest and abdomen/pelvis is medically necessary. CT Chest (with contrast or without contrast) is medically necessary to evaluate for lung metastases. Cross-sectional imaging of the abdomen/pelvis using CT Abdomen/Pelvis (with or with and without contrast) or MRI Abdomen as well as MRI Pelvis (with and without contrast) are medically necessary for characterization of the primary tumor and evaluation for metastatic disease. If recurrence is suspected, the same imaging studies should be completed as was done for initial staging. Additional imaging may be needed to assess other suspicious sites of disease based on clinical signs/symptoms.

NCCN endorsed the use of FDG PET/CT in addition to diagnostic CT or MRI for initial imaging of suspected adrenocortical carcinoma. FDG PET/CT scan is a valuable

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

problem-solving tool; thus, FDG PET/CT is medically necessary to characterize inconclusive findings CT/MRI.

CT imaging is the standard approach in surveillance. In individuals who had complete response to definitive therapy, the recommendation is annual imaging for 5 years after completion of treatment as the rate of recurrence is <25% and overall survival rate approaches 74% to 95% at 5 years. In individuals with metastatic disease on maintenance therapy or being monitored off treatment, the frequency of CT imaging is shortened and repeated at 3 month intervals for up to 5 years.[1,19-22]

Colorectal Cancer – General Considerations (ONC-16.0)

ON.CC.0016.0.A

v3.0.2026

- Neuroendocrine tumors of the bowel are covered in: **Neuroendocrine Cancers and Adrenal Tumors (ONC-15)**.
- Appendiceal adenocarcinoma (including pseudomyxoma peritonei) follows imaging guidelines for colorectal cancer.
- For squamous cell carcinoma of the rectum, see: **Anal Carcinoma (ONC-24)**.

Health Equity Considerations

In 2021, it was estimated that approximately 53,000 individuals in the United States died from colorectal cancer. However, these mortality rates do not affect groups of individuals equally. These disparities - differences in health outcomes that are related to factors such as social or economic disadvantages - often cause individuals to experience higher rates of colon cancer incidence and mortality.[16]

While the rates of new colorectal cancer have been declining over time with the increase in screening colonoscopies, the rate of decline is not equitably distributed among individual groups. Data from the National Cancer Registries between 2012 and 2016 showed that Black individuals had an almost 20% higher rate of colorectal cancer than White individuals. According to a 2018 report from the Surveillance, Epidemiology, and End Results Program (SEER), the incidence rates for Black individuals was 39.8 per 100,000 individuals compared to 36.4 for White individuals. These data also showed that Black individuals have an age-adjusted mortality rate of 16.8 per 100,000 compared to 13.1 for White individuals.[16]

Native Alaskans, who represent about 3% of the US population, have the highest rates of colorectal cancer and highest mortality rates in the world. Approximately 2.6 million American Indian/Alaska Native individuals receive healthcare through Indian Health Service or tribal care facilities - which are historically underfunded - and as a result, many of these facilities do not offer cancer screenings. Since screenings and cancer prevention services are not guaranteed in these facilities, health disparities in the Native community are often seen.[17]

Colorectal cancer is the second leading cause of cancer deaths in the Hispanic community in the US. While screenings for colorectal cancer have increased in the past 20 years, Hispanics in the US are still less likely to undergo colorectal cancer screenings than Black and White US residents.[18]

Colorectal Cancer – Initial Work-up/ Staging (ONC-16.2)

ON.CC.0016.2.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Carcinoma within a polyp that is completely removed	• No advanced imaging
• Biopsy-proven invasive colon adenocarcinoma • Colonoscopy findings consistent with colon cancer	• CT Chest with contrast (CPT® 72160) or without contrast (CPT® 72150) AND • CT Abdomen and Pelvis with contrast (CPT® 74177)
• Biopsy-proven invasive rectal adenocarcinoma • Colonoscopy findings consistent with rectal cancer	• CT Chest with contrast (CPT® 71260) OR without contrast (CPT® 71250) AND ◦ Any one of the following: ▪ CT Abdomen with contrast (CPT® 74160) OR MRI Abdomen without and with contrast (CPT® 74183) AND ▪ MRI Pelvis without and with contrast (CPT® 72197) OR MRI Pelvis without contrast (CPT® 72195) (in addition to CT Pelvis if already performed)
• Further evaluation of an inconclusive liver lesion seen on CT • Potentially resectable liver metastases	• MRI Abdomen without and with contrast (CPT® 74183)
Rectal adenocarcinoma with ANY one of the following: • Rectal MRI is contraindicated • Rectal MRI is inconclusive • Superficial lesions	• Endorectal ultrasound (CPT® 76872)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
ONE of the following: • Isolated metastatic lesion(s) on other imaging and individual is a candidate for aggressive surgical resection or other localized treatment to metastasis for curative intent • Inconclusive conventional imaging	• PET/CT (CPT® 78815)

Evidence Discussion

- Carcinoma within a polyp that is completely resected does not require advanced imaging.[1]
- Invasive cancer at any stage requires advanced imaging with CT of Chest/Abdomen/Pelvis with contrast needed to adequately visualize lung, nodal, and especially liver lesions with MRI of abdomen appropriate in the event of unclear liver lesions. The chest CT can identify lung metastases, which occur in approximately 4% - 9% of individuals with colon and rectal cancer.[11]
- Rectal cancer requires additional dedicated imaging with MRI Pelvis that is superior to CT imaging to locally stage this form of colon cancer with endorectal/endoscopic ultrasound (EUS), providing additional staging information when MRI is contraindicated/inconclusive/superficial. MRI is considered superior to EUS due to the latter's limitations in regard to high/bulky tumors, tumor deposits, or vascular invasion.[12] The American College of Radiology also supports MRI Abdomen for local staging, as well as for the assessment of hepatic and extrahepatic metastatic disease.[19]
- PET/CT is reserved for inconclusive CT/MRI imaging and to confirm isolated metastases that are amenable to definitive localized treatment with curative intent.[1]

Colorectal Cancer – Restaging/ Recurrence (ONC-16.3)

ON.CC.0016.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
• Complete resection • Individuals receiving post-operative adjuvant chemotherapy	• See: **Surveillance/Follow-up (ONC-16.4)**
Recurrence suspected for colon cancer (i.e., signs or symptoms, elevated CEA)	• CT Chest with contrast (CPT® 72160) or without contrast (CPT® 72150) AND • CT Abdomen and Pelvis with contrast (CPT® 74177)
Recurrence suspected for rectal cancer (i.e., signs or symptoms, elevated CEA)	• CT Chest with contrast (CPT® 71260) OR without contrast (CPT® 71250) AND ◦ Any one of the following: ▪ CT Abdomen with contrast (CPT® 74160) OR MRI Abdomen without and with contrast (CPT® 74181) AND ▪ MRI Pelvis without and with contrast (CPT® 72197) OR MRI Pelvis without contrast (CPT® 72195) (in addition to CT Pelvis if already performed)
After completion of planned neoadjuvant therapy	Prior to surgical resection in individuals with non-metastatic rectal cancer: • CT Chest with contrast (CPT® 71260) and Any ONE of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen with contrast (CPT® 74160) and MRI Pelvis without and with contrast (CPT® 72197)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Unresected primary disease or metastatic disease on chemotherapy	Every 2 cycles of chemotherapy treatment and at the completion of chemoradiotherapy: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of other involved or symptomatic areas
Individuals on adjuvant chemo/RT	3 months and 4-5 months after start of treatment: • CT Chest with contrast (CPT® 71260) AND • ONE of the following: ◦ MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) OR ◦ CT Abdomen with contrast (CPT® 74160) and MRI Pelvis without and with contrast (CPT® 72197) OR ◦ CT Abdomen and Pelvis with contrast (CPT® 74177)
Individuals on total neoadjuvant therapy (no resection performed or planned)	6 months and 8.5-9.5 months after start of treatment: • CT Chest with contrast (CPT® 71260) AND • ONE of the following: ◦ MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) OR ◦ CT Abdomen with contrast (CPT® 74160) and MRI Pelvis without and with contrast (CPT® 72197) OR ◦ CT Abdomen and Pelvis with contrast (CPT® 74177)
• Further evaluation of an inconclusive liver lesion seen on CT • Potentially resectable liver metastases	• MRI Abdomen without and with contrast (CPT® 74183)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
ONE of the following: • Postoperative elevated or rising CEA or LFTs with negative recent conventional imaging • Isolated metastatic lesion(s) on other imaging and individual is a candidate for aggressive surgical resection or other localized treatment (thermal ablation/embolization) to metastasis for curative intent • Differentiate local tumor recurrence from postoperative and/or post-radiation scarring • Liver-directed therapies (resection, ablation, embolization) are being considered and member has a contraindication to IV contrast	• PET/CT (CPT® 78815)
New or worsening pelvic pain and recent CT imaging negative or inconclusive	• MRI Pelvis without and with contrast (CPT® 72197) or without contrast (CPT® 72195)

Evidence Discussion

- If colon cancer recurrence is suspected, CT Chest/Abdomen/Pelvis is the first line of imaging.[1]
- NCCN stated that ctDNA is not recommended for surveillance.[1]
- Upon completion of neoadjuvant therapy, to ensure the cancer has not progressed prior to definitive surgery, repeat imaging of the chest, abdomen and pelvis is medically necessary.[1]
- With measurable disease or unresected primary disease on chemotherapy, CT imaging is medically necessary every 2 cycles of treatment to assess response and appropriateness to continue the same treatment or change to new therapy.[1]
- MRI Abdomen is medically necessary for inconclusive liver lesion or to better define resectability.[1]
- PET/CT may be used in specific situations to better determine cancer recurrence if CT/MRI is inconclusive. These results may allow aggressive interventions (e.g., surgery, radiation, liver directed therapy) to take place with goal of cure, explain elevated or rising CEA level or LFTs with negative conventional imaging and can also

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

be useful to differentiate surgical/radiation scarring from cancer. A systemic review and meta-analysis of 11 studies using PET/CT with elevated CEA and negative CT Chest/Abdomen/Pelvis showed a sensitivity of 94% and specificity of 77% in detection of tumor recurrence.[1,6]

Click Here to Return to the Main TOC

Colorectal Cancer – Surveillance/Follow-up (ONC-16.4)

ON.CC.0016.4.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Colon and rectal adenocarcinoma: • Stage I	• No routine advanced imaging
Colon and rectal adenocarcinoma treated with surgery: • Stage II-III	• CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) after completion of surgery and then annually for 5 years
Stage II-III rectal cancer treated with chemoradiation alone (no surgical treatment)	• CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) after completion of chemoradiotherapy and then annually for 5 years AND • MRI Pelvis (CPT® 72197) without and with contrast or without contrast (CPT 72195) every 6 months for 3 years
Colon and rectal adenocarcinoma: • Stage IV or distant metastatic disease (post definitive treatment of all measurable disease or being observed off therapy)	• CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) every 6 months for 2 years and then annually for 3 years
Measurable metastatic disease on maintenance therapy	Every 3 months for up to 5 years after completion of active treatment: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Rectal cancer treated with transanal excision alone	Any one of the following every 6 months for 5 years: • Endorectal ultrasound (CPT® 76872) • MRI Pelvis without and with contrast (CPT® 72197) • MRI Pelvis without contrast (CPT® 72195)
Pseudomyxoma peritonei	ONE of each of the following, every 3 months for first year, then every 6 months for 4 more years: • CT Chest with (CPT® 71260) or CT Chest without contrast (CPT® 71250) • CT Abdomen and Pelvis with contrast (CPT® 74177) or MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast or without contrast (CPT® 72195)

Evidence Discussion

- Up to 95% of recurrences occur in the first 5 years after surgery with 80% occurring in the first 3 years, many of which can still be cured, supporting the need for CT imaging.
- Given the >90% cure rate with Stage I cancer, routine imaging is not medically necessary.[1]
- Given the recurrence rate between 20%-30% in Stage II-III disease, CT Chest/ Abdomen/Pelvis is medically necessary after completion of surgery (new baseline) and annually for 5 years. More frequent imaging has a lower level of support based on the following trials: FACS, COLOFOL, CEAwatch, and PRODIGE 13.[15]
- For Stage IV cancer status post definitive treatment or being observed off therapy, CT imaging is medically necessary every 6 months for 2 years then annually for 3 years.[15]
- For Stage IV cancer that is measurable and on maintenance therapy, CT imaging is medically necessary every 3 months for up to 5 years after completion of active treatment.
- For rectal cancer treated with transanal excision alone, due to higher risk of local recurrence, endorectal ultrasound (EUS) should be performed every 6 months for 5 years with pelvic MRI reserved for abnormal findings on EUS or EUS can't be performed as well as new signs/symptoms concerning for local recurrence.[2]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Treatment with chemoradiation alone (no surgery) is becoming more common in the setting of rectal cancer in the presence of a complete response to therapy with 5-year survival rates exceeding 80% in several trials. These individuals require additional follow-up studies to include MRI Pelvis every 6 months for 3 years as well as digital rectal exam (DRE)/endoscopy every 3-4 months for 2 years and every 6 months for 3 more years to assess for local recurrence even without signs/symptoms of recurrence.[2]
- Pseudomyxoma peritonei is a condition associated with appendiceal cancer and requires close imaging follow-up due to high risk of recurrence; thus, imaging with CT/MRI is medically necessary every 3 months for year 1 and every 6 months for 4 more years.[1]

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Small Bowel Cancer – Initial Work-up/ Staging (ONC-16.5)

ON.CC.0016.5.A
v3.0.2026

This section provides imaging guidelines for small bowel adenocarcinoma arising from the duodenum, jejunum, and ileum.

Indication	Medically Necessary Imaging Study
Carcinoma within a polyp that is completely removed	• No advanced imaging
Invasive adenocarcinoma	• CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast ◦ MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) if CT is inconclusive or cannot be performed

Evidence Discussion

- Cancerous polyps that are completely removed do not require imaging.[1]
- Invasive cancer at any stage requires advanced imaging with CT of Chest/Abdomen/ Pelvis with contrast needed to adequately visualize lung, nodal, and especially liver lesions with MRI of abdomen/pelvis appropriate in the event the CT is inconclusive or cannot be performed.[1]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Small Bowel Cancer – Restaging/ Recurrence (ONC-16.6)

ON.CC.0016.6.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Complete resection	• See Surveillance below
Recurrence suspected	• CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast
Unresected primary disease or metastatic disease on chemotherapy	Every 2 cycles of chemotherapy: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177)
Further evaluation of an inconclusive liver lesion seen on CT	• MRI Abdomen without and with contrast (CPT® 74183)
ONE of the following: • Postoperative elevated or rising CEA or LFTs with negative recent conventional imaging • Isolated metastatic lesion(s) on other imaging and individual is a candidate for aggressive surgical resection or other localized treatment to metastasis for curative intent	• PET/CT (CPT® 78815)

Evidence Discussion

- If recurrence is suspected, CT Chest/Abdomen/Pelvis with contrast is the first line of imaging.
- With measurable disease or unresected primary disease on chemotherapy, CT imaging is medically necessary every 2 cycles of treatment to assess response and appropriateness to continue the same treatment or change to new therapy.
- MRI Abdomen is medically necessary for inconclusive liver lesion on CT

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- PET/CT may be used in specific situations to better determine cancer recurrence if CT/MRI is inconclusive. These results may allow aggressive interventions (surgery, radiation, liver directed therapy) to take place with goal of cure and also explain elevated or rising CEA level or LFTs with negative conventional imaging.[3]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Small Bowel Cancer – Surveillance/ Follow-up (ONC-16.7)

ON.CC.0016.7.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Stage I-III	• CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast after completion of surgery, and then annually for 5 years
Stage IV - Metastatic disease (post definitive treatment of all measurable disease, or being observed off therapy)	• CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast every 6 months for 2 years and then annually for 3 years
Measurable metastatic disease on maintenance therapy	Every 3 months for up to 5 years after completion of active treatment: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177)

Evidence Discussion

- Stage I, II and III cancers undergo CT Chest/Abdomen/Pelvis at completion of surgery then annually for 5 years, similar to Colorectal guidelines due to lack of data regarding optimal approach.[3,15]
- For Stage IV cancer s/p definitive treatment or being observed off therapy, CT imaging is medically necessary every 6 months for 2 years then annually for 3 years.
- For Stage IV cancer that is measurable and on maintenance therapy, CT imaging is medically necessary every 3 months for up to 5 years after completion of active treatment.

Renal Cell Cancer (RCC) – General Considerations (ONC-17.0)

ON.RC.0017.0.A

v3.0.2026

- PET is considered not medically necessary for initial diagnosis, staging or restaging of renal cell cancer.
- A minority of adult individuals with renal cell cancer (RCC) will have translocations in TFE3 or TFEB, which have a different natural history than “adult type” RCC. Individuals of any age with TFE3 or TFEB translocated RCC should be imaged according to guidelines in **Pediatric Renal Cell Carcinoma (RCC) (PEDONC-7.4)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
- Individuals of any age with a Wilms tumor should be imaged according to guidelines in section **Unilateral Wilms Tumor (UWT) (PEDONC-7.2)** or **Bilateral Wilms Tumor (BWT) (PEDONC-7.3)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
- Oncocytoma in individuals of all ages should be imaged according to these guidelines.

Renal Cell Cancer (RCC) – Suspected/ Diagnosis (ONC-17.1)

ON.RC.0017.1.A
v3.0.2026

Indication	Medically Necessary Imaging Study
• Solitary renal mass suspicious for renal cell cancer	• See: **Indeterminate Renal Lesion (AB-35.1)** in the Abdomen Imaging Guidelines for evaluation of suspected renal malignancies • CT Chest with contrast with (CPT® 71260) or without contrast (CPT® 71250)

Evidence Discussion

In individuals with RCC or suspicion of RCC, complete staging is typically completed with chest radiography (CXR) or chest CT. CT Chest is preferred.[1,17]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Renal Cell Cancer (RCC) – Initial Work-up/Staging (ONC-17.2)

ON.RC.0017.2.A
v3.0.2026

Indication	Medically Necessary Imaging study
All individuals	If not done previously: • CT Chest with (CPT® 71260) or without (CPT® 71250) contrast • CT Abdomen and Pelvis, contrast as requested
ANY of the following: • Extension of tumor into the vena cava by other imaging • Inconclusive findings on CT	• MRI Abdomen without and with contrast (CPT® 74183)
Bone pain	• Bone scan (CPT® 78306) (See: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes)
EITHER of the following: • Signs/symptoms suspicious for brain metastases • Newly diagnosed stage IV/ metastatic RCC	• MRI Brain without and with contrast (CPT® 70553)

Evidence Discussion

American Urological Association (AUA) and the National Comprehensive Cancer Network (NCCN) guidelines stated that pre- and post-contrast enhanced axial imaging, either CT or MRI, is the ideal imaging technique for the diagnosis and staging of clinically localized renal masses. Contrast-enhanced abdominal imaging best characterizes the mass, provides information regarding both the affected and unaffected renal unit, can assess extrarenal tumor spread (venous invasion or regional lymph nodes), and evaluates the adrenal glands and other abdominal organs for visceral metastasis.[1,20,21]

Masses initially diagnosed by ultrasound should be confirmed with pre- and post-contrast enhanced imaging.[1]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

In individuals with RCC or suspicion of RCC, complete staging is typically completed with chest radiography (CXR) or chest CT. Chest CT is preferred.[1] Bone scans should be reserved primarily for individuals with bone pain as the prevalence of osseous metastasis for localized renal cell cancer has been shown to be low in individuals without symptoms suggestive of osseous metastasis. Brain imaging is reserved for individuals with neurologic symptoms, as most individuals with metastasis to the central nervous system are symptomatic, or individuals with newly diagnosed metastatic disease.[1]

Renal Cell Cancer (RCC) – Restaging/ Recurrence (ONC-17.3)

ON.RC.0017.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Unresectable disease or metastatic disease on systemic therapy	Every 2 cycles of treatment (commonly every 6 to 8 weeks): • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis, contrast as requested (CPT® 74177, CPT® 74178, or CPT® 74176) • CT with contrast of other involved or symptomatic areas
Recurrence suspected	• CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis, contrast as requested (CPT® 74177, CPT® 74178, or CPT® 74176)
EITHER of the following: • Biopsy-proven recurrent/ metastatic disease • Signs or symptoms concerning for brain metastases	• MRI Brain without and with contrast (CPT® 70553)

Evidence Discussion

Individuals presenting with findings suggesting a new renal primary or local recurrence of renal malignancy should undergo metastatic evaluation including chest and abdominal imaging.[1,20,21] The most common sites of distant metastasis include lung, bone, retroperitoneal and mediastinal nodes, liver, brain, or multiple sites.[29,30]

Renal Cell Cancer (RCC) – Surveillance (ONC-17.4)

ON.RC.0017.4.A
v3.0.2026

Indication	Medically Necessary Imaging Study
RCC on active surveillance of renal mass <1cm	ALL of the following, once within 6 months of surveillance initiation and annually thereafter: • CT Abdomen, contrast as requested (CPT® 74170, CPT® 74160, or CPT® 74150) or MRI Abdomen without and with contrast (CPT® 74183) • Chest x-ray ◦ CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250) is medically necessary instead of chest x-ray for any of the following: ▪ Known prior thoracic disease ▪ New or worsening pulmonary symptoms ▪ New or worsening chest x-ray findings
RCC on active surveillance of renal mass ≥1cm	ALL of the following, every 3 months for year 1, every 6 months for years 2 and 3 and annually thereafter: • CT Abdomen, contrast as requested (CPT® 74170, CPT® 74160, or CPT® 74150) OR MRI Abdomen without and with contrast (CPT® 74183) • Chest x-ray ◦ CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250) is medically necessary instead of chest x-ray for any of the following: ▪ Known prior thoracic disease ▪ New or worsening pulmonary symptoms ▪ New or worsening chest x-ray findings

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Follow up after post-ablation therapy of RCC	EITHER of the following, at 1 to 3 months, 6 months, and 12 months post-ablation and then annually thereafter: • CT Abdomen, contrast as requested (CPT® 74170), CPT® 74160, or CPT® 74150 or • MRI Abdomen without and with contrast (CPT® 74183) AND Annually for 5 years: • Chest x-ray or CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250)
Follow up after SBRT	ONE of each of the following, every 3 months for 1 year, every 6 months in year 2, every 9 months in years 3-4, and once in year 5 (to complete 5 years surveillance): • CT Chest with (CPT® 71260) or CT Chest without contrast (CPT® 71250) • CT Abdomen, contrast as requested (CPT® 74170, CPT® 74160, or CPT® 74150) or MRI Abdomen without and with contrast (CPT® 74183)
Stage I RCC, after partial or radical nephrectomy	ONE of each of the following, 3 to 12 months post-resection: • CT Chest with (CPT® 71260) or CT Chest without contrast (CPT® 71250) • CT Abdomen, contrast as requested (CPT® 74170, CPT® 74160, or CPT® 74150) or MRI Abdomen without and with contrast (CPT® 74183) ONE of each of the following, annually for 5 years: • CT Chest with (CPT® 71260) or CT Chest without (CPT® 71250) contrast • MRI Abdomen without and with contrast (CPT® 74183) or CT Abdomen, contrast as requested (CPT® 74170, CPT® 74160, or CPT® 74150)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Stage II RCC, post-nephrectomy	ONE of each of the following, 3 to 6 months post-resection: • CT Chest with (CPT® 71260) or CT Chest without (CPT® 71250) contrast • CT Abdomen, contrast as requested (CPT® 74170, CPT® 74160, or CPT® 74150), or CT Abdomen and Pelvis, contrast as requested (CPT® 74177, CPT® 74176, or CPT® 74178), or MRI Abdomen without and with contrast (CPT® 74183) +/- MRI Pelvis without and with contrast (CPT® 72197) ONE of each of the following, every 6 months for 2 years, then annually until year 5: • CT Chest with (CPT® 71260) or CT Chest without (CPT® 71250) contrast • MRI Abdomen without and with contrast (CPT® 74183) +/- MRI Pelvis without and with contrast (CPT® 72197), or CT Abdomen, contrast as requested (CPT® 74170, CPT® 74160, or CPT® 74150), or CT Abdomen and Pelvis, contrast as requested (CPT® 74177, CPT® 74176, CPT® 74178)
Stage III RCC, post-nephrectomy	ONE of each of the following, 3 to 6 months post-resection: • CT Chest with (CPT® 71260) or CT Chest without (CPT® 71250) contrast • CT Abdomen, contrast as requested (CPT® 74170, CPT® 74160, or CPT® 74150), or CT Abdomen and Pelvis, contrast as requested (CPT® 74177, CPT® 74176, or CPT® 74178), or MRI Abdomen without and with contrast (CPT® 74183) +/- MRI Pelvis without and with contrast (CPT® 72197) ONE of each of the following, every 3 months for 3 years, then annually to year 5: • CT Chest with (CPT® 71260) or CT Chest without (CPT® 71250) contrast • CT Abdomen, contrast as requested (CPT® 74170, CPT® 74160, or CPT® 74150), or CT Abdomen and Pelvis, contrast as requested (CPT® 74177, CPT® 74176, CPT® 74178), or MRI Abdomen without and with contrast (CPT® 74183) +/- MRI Pelvis without and with contrast (CPT® 72197)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Stage IV/metastatic disease on maintenance therapy or being observed off therapy	ONE of each of the following, every 3 months for up to 5 years after completion of active treatment: • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) • CT Abdomen, contrast as requested (CPT® 74170, CPT® 74160, or CPT® 74150), or CT Abdomen and Pelvis contrast as requested (CPT® 74177, CPT® 74176, or CPT® 74178), or MRI Abdomen without and with contrast (CPT® 74183) +/- MRI Pelvis without and with contrast (CPT® 72197)

Evidence Discussion

Active surveillance Stage T1a:

Active surveillance entails serial abdominal imaging in order to study the growth rate of the tumor, and abdominal imaging (CT or MRI with contrast) is medically necessary within 6 months from initiation of active surveillance; subsequent imaging (with CT, MRI, or ultrasound [US]) is medically necessary annually thereafter. CT and MRI have both been found to accurately predict pathologic tumor size in a retrospective analysis.[23] Therefore, best clinical judgment should be used in choosing the imaging modality. A chest x-ray or chest CT at baseline and annually is medically necessary as clinically indicated to assess for pulmonary metastases. Repeat chest imaging can be considered if intervention is being contemplated.[1]

Follow up after ablative therapy for Stage T1a:

An abdominal imaging, either CT or MRI with and without IV contrast (unless otherwise contraindicated), is medically necessary at 1 through 6 months to assess treatment response, followed by annual abdominal CT or MRI (preferred) for 5 years or longer as clinically indicated. If the individual cannot receive IV contrast, MRI is preferred.[1]

Follow up after partial or radical nephrectomy for Stages 1-2:

For Stage I RCC, abdominal CT or MRI (preferred) is medically necessary within 3 to 12 months following renal surgery, then annually for up to 5 years or longer as clinically indicated. For individuals with stage II RCC, an increase in abdominal imaging frequency is medically necessary, with baseline abdominal CT or MRI (preferred) every 6 months for 2 years, then annually for up to 5 years or longer, as clinically indicated.[1]

Yearly chest x-ray or CT is medically necessary for at least 5 years and as clinically indicated thereafter.[1]

Follow up for individuals with Stage 3 RCC:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

A baseline abdominal CT or MRI is medically necessary within 3 to 6 months following surgery, followed by CT, MRI (preferred), or US every 3 to 6 months for at least 3 years, and annually thereafter for up to 5 years.[1]

A baseline chest CT within 3 to 6 months following surgery is also medically necessary along with continued imaging (CT preferred) every 3 to 6 months for at least 3 years, and annually thereafter for up to 5 years.[1]

CT is the preferred modality for those with a high risk of recurrence.

Follow up for an individual with relapse or unresectable disease or Stage 4 RCC:

Chest, abdominal and pelvic imaging is medically necessary at baseline and then as clinically indicated based on clinical status, and therapeutic schedule.[1]

Transitional Cell Cancer – General Considerations (ONC-18.0)

ON.TS.0018.0.A

v3.0.2026

- Transitional cell cancers can include: tumors of the bladder, ureters, prostate, urethra, or renal pelvis. For primary cancer of the kidney, see: **Renal Cell Cancer (RCC) (ONC-17)**.
- Most common histology of bladder cancer is transitional cell (TCC) or urothelial carcinoma (UCC). Rare histologies include adenocarcinoma, squamous cell (imaged according to **Transitional Cell Cancer (ONC-18)**), or small cell (imaged according to **Extrathoracic Small Cell and Large Cell Neuroendocrine Tumors (ONC-31.8)**).
- Urachal cancer is rare type of bladder cancer; the most common histology is adenocarcinoma. These are imaged according to muscle invasive bladder cancer.
- PET is not medically necessary in transitional cell cancer with exception noted below in **Transitional Cell Cancer – Initial Work-up/Staging (ONC-18.2)**.

Transitional Cell Cancer – Initial Work-up/Staging (ONC-18.2)

ON.TS.0018.2.A
v3.0.2026

Indication	Medically Necessary Imaging Study
All individuals	ONE of the following: • CT Abdomen and Pelvis without and with contrast (CPT® 74178) ◦ MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast if contraindication to CT contrast • CT Abdomen and Pelvis without contrast (CPT® 74176) with retrograde pyelogram or renal ultrasound (CPT® 76770 or CPT® 76775) in individuals who cannot receive either CT or MRI contrast
Sessile or high-grade tumors	In addition to the imaging above, if not already performed: • MRI Pelvis without and with contrast (CPT® 72197)
ANY of the following: • Muscle invasive bladder carcinoma • Urethral carcinoma • Urothelial carcinoma of the prostate	• CT Chest without (CPT® 71250) or with (CPT® 71260) contrast
Individuals without metastatic disease, when requested by operating surgeon for operative planning	• CT with contrast or MRI without and with contrast of all operative sites

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Evaluation of suspected bone metastasis: • Individuals with symptoms of bone metastasis • Laboratory indicators of bone metastasis • Individuals with muscle invasive disease • Suspected sites of extra-osseous metastatic disease	Any ONE of the following: • Bone scan (CPT® 78306) (see: **Nuclear Medicine (NM) Imaging in Oncology [ONC-1.3]** for additional bone scan codes) • MRI without and with contrast of areas of suspected involvement • FDG PET/CT (CPT® 78815)
To evaluate inconclusive findings on conventional imaging	• PET/CT (CPT® 78815)
Suspected brain metastases	See: **Brain Metastases (ONC-31.3)**

Evidence Discussion

Initial staging of non-muscle invasive bladder cancer (NMIBC)

A clinician should perform upper tract imaging as a component of the initial evaluation of an individual with bladder cancer. NCCN guidelines recommend CT urography CTU (CT of the abdomen and pelvis without and with IV contrast with excretory imaging), which is an imaging study that is tailored to improve visualization of both the upper and lower urinary tracts. CT scan can require a significant dose of ionizing radiation, but the speed of image acquisition reduces the potential for motion artifact.

MR urography (MRU) may be appropriate, especially in an individual with poor renal function or contrast allergy. MRU can be degraded due to motion artifact, but there is no ionizing radiation with this imaging modality.

CTU and MRU allow for comprehensive evaluation of the genitourinary tract, as well as assessment of retroperitoneal and pelvic lymph nodes.

Renal ultrasound (US) or CT without contrast may be utilized in conjunction with retrograde ureteropyelography in individuals who cannot receive either iodinated or gadolinium-based contrast material. Ultrasound requires no ionizing radiation, but is not sufficient for evaluation alone, and must be combined with either retrograde ureteropyelography or ureteroscopy to completely evaluate the upper urinary tract.[1]

NCCN guidelines stated that chest imaging may not be necessary in the initial staging of non-invasive disease, as the risk of chest metastasis in individuals with TA or T1 NMBIC is low.[1,8]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

FDG PET/CT is not medically necessary to delineate the anatomy of the upper urinary tract as it does not provide detailed imaging of the bladder. Thus, it is reserved as a problem-solving tool when other imaging studies are inconclusive.[1]

Initial staging of non-metastatic muscle-invasive bladder cancer (MIBC)

Prior to muscle-invasive bladder cancer management, clinicians should perform a complete staging evaluation, including imaging of the chest and cross-sectional imaging of the abdomen and pelvis with intravenous contrast if not contraindicated. Laboratory evaluation should include a comprehensive metabolic panel (complete blood count, liver function tests, alkaline phosphatase, and renal function).

All individuals with MIBC require imaging of the thorax. Chest radiography is an effective screening exam. Any abnormality should be followed up with a CT exam.

For sessile or high-grade tumors, MRI Pelvis is medically necessary in addition to CTU for local staging.[1]

NCCN indicated that bone imaging is medically necessary if there are clinical indications of bone metastases or in individuals with muscle-invasive disease.[1]

FDG PET/CT is not medically necessary to delineate the anatomy of the upper urinary tract as it does not provide detailed imaging of the bladder. Thus, it is reserved as a problem-solving tool when other imaging studies are inconclusive.

Initial staging of Urothelial Carcinoma of the prostate/primary carcinoma of the urethra

Initial work up is similar to non-metastatic muscle invasive bladder cancer and should include Chest CT, CTU or MRU.

Transitional Cell Cancer – Restaging/ Recurrence (ONC-18.3)

ON.TS.0018.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
After definitive surgery	• CT Abdomen and Pelvis with contrast (CPT® 74177) or CT Abdomen and Pelvis without and with contrast (CPT® 74178) for post-operative baseline ◦ MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast if contraindication to CT contrast
Recurrence suspicion	• CT Abdomen and Pelvis with contrast (CPT® 74177) or with and without contrast (CPT® 74178) ◦ MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast if contraindication to CT contrast • CT Chest with contrast (CPT® 71260) for ANY of the following: ◦ Known prior thoracic disease ◦ New or worsening pulmonary symptoms ◦ New or worsening chest x-ray findings ◦ Known prior or suspected muscle invasive disease
After neoadjuvant therapy and before resection	• CT Chest with contrast (CPT® 71260) and CT Urogram (CPT® 74178)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Monitoring therapy for metastatic disease	Every 2 cycles of therapy: • CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast if contraindication to CT contrast • CT Chest with contrast (CPT® 71260) for ANY of the following: ◦ Known prior thoracic disease ◦ New or worsening pulmonary symptoms ◦ New or worsening chest x-ray findings
To evaluate inconclusive findings on conventional imaging	• PET/CT (CPT® 78815)

Evidence Discussion

Individuals presenting with findings suggesting a new primary or local recurrence of malignancy should undergo metastatic evaluation including abdominal and pelvic imaging. The most common sites for metastasis include lymph nodes, bone, lung, liver, and peritoneum.[10] The recommended imaging for restaging of suspected recurrence mirrors that which is performed in initial staging.[1,6]

Transitional Cell Cancer – Surveillance/ Follow-up (ONC-18.4)

ON.TS.0018.4.A
v3.0.2026

Indication	Medically Necessary Imaging Study
ANY of the following: • Papillary urothelial neoplasm of low malignant potential • Low risk lesions ◦ Solitary Ta lesions ≤3cm • Intermediate risk lesions ◦ Low-grade >3cm ◦ Low-grade multifocal ◦ T1 lesions ◦ High-grade solitary Ta ≤3cm	One-time baseline imaging at the end of therapy: • CT Urogram (CPT® 74178) or MR Urogram (CPT® 74183 and CPT® 72197) • Further advanced imaging is not routinely medically necessary for surveillance
ANY of the following high-risk non-muscle invasive transitional cell carcinoma of the bladder or upper tracts: • Multifocal high-grade lesions • High-grade lesions >3cm • Superficial and minimally invasive (Tis and T1) • BCG unresponsive • Lymphovascular invasion • Prostatic urethral invasion	• CT Urogram (CPT® 74178) or MR Urogram (CPT® 74183 and CPT® 72197) (imaging as performed at initial staging) every 1-2 years for 10 years
Non-muscle-invasive transitional carcinoma of the bladder treated with cystectomy	• CT Urogram (CPT® 74178) or MR Urogram (CPT® 74183 and CPT® 72197) (imaging as performed at initial staging) at 3 and 12 months post-cystectomy, and then annually for years 2-5

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Muscle invasive lower and upper genitourinary tumors treated with cystectomy, nephrectomy, or chemoradiation	Every 3-6 months for 2 years, then annually for 3 more years: • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250), and CT Abdomen and Pelvis with contrast (CPT® 74177) or without and with contrast (CPT® 74178) OR • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250), and MR Urogram (CPT® 74183 and CPT® 72197)
Measurable metastatic disease on maintenance therapy or being monitored off therapy	Every 3 months for up to 5 years after completion of active treatment: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177), CT Urogram (CPT® 74178), or MR Urogram (CPT® 74183 and CPT® 72197) (imaging as performed at initial staging)
Urethral cancers (high-risk T1 or greater) and urothelial carcinoma of the prostate	Every 3-6 months for 2 years, then annually: • CT Abdomen and Pelvis with contrast (CPT® 74177) or without and with contrast (CPT® 74178) OR • MR Urogram (CPT® 74183 and CPT® 72197) AND • Chest x-ray ◦ CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) for any of the following: ▪ Signs/symptoms of pulmonary disease ▪ Abnormal chest x-ray ▪ Prior involvement of the chest

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion

Surveillance of non-muscle invasive bladder cancer[1,7]

In an asymptomatic individual with a history of low-risk NMIBC, a clinician should not perform routine surveillance upper tract imaging after the initial baseline.

For an intermediate or high-risk individual, a clinician should perform surveillance upper tract imaging at 1-2 year intervals. Initially, clinicians should obtain imaging at 12 months, then every 1-2 years up to 10 years. CT urography (CTU), MRU, or retrograde ureteropyelography with non-contrast CT or US or ureteroscopy with a non-contrast CT or US are medically necessary.

Routine chest imaging is not medically necessary for individuals with NMBIC unless an abnormality is identified with chest radiography.

Surveillance of non-metastatic muscle-invasive bladder cancer[1,7]

Clinicians should obtain chest imaging and cross-sectional imaging of the abdomen and pelvis with CT or MRI at 6-12 month intervals for 2-3 years and then may continue annually.

Prostate Cancer – General Considerations (ONC-19.0)

ON.PR.0019.0.A

v3.0.2026

- Prostate cancer screening begins at age 45 for individuals at average risk of prostate cancer. However, individuals at high-risk may begin screening at age 40. High-risk features include:
  - Black/African American identity
  - germline mutations (BRCA1 or 2, HOXB13, ATM, CHEK2, or mismatch repair genes (MLH1, MSH2, MSH6, PMS2) that increase the risk of prostate cancer
  - family history of first or second-degree relative with prostate, male breast, colorectal, pancreatic, endometrial or female breast cancer at age <45 years
- Treatment of benign prostatic hyperplasia with 5-alfa reductase inhibitors (such as finasteride and dutasteride) can falsely reduce the measured PSA levels by 50%. Thus, the reported PSA level should be doubled when prostate cancer is suspected in individuals on these medications.
- Individuals with high-risk adverse clinical and pathological factors may benefit from a more aggressive diagnostic and therapeutic approach at the time of relapse after initial treatment. These factors include pre-treatment Gleason score of ≥8, pre-treatment clinical stage of cT3b or higher, positive surgical margins, post-treatment PSA doubling time of <3 months, and an interval to biochemical failure of <3 years after initial treatment.
- PET/CT scans using ^{18}F-FDG radiotracer are not medically necessary for evaluation of prostate cancer.
- ^{11}C Choline, ^{18}F-Fluciclovine (AXUMIN®), and PSMA-specific radiopharmaceuticals have recently gained FDA approval for evaluation of prostate cancer. Optimal detection rates for these radiotracers vary greatly with PSA levels. False positive rate is high and histological confirmation of positive sites is recommended.
- PSMA-specific PET radiopharmaceuticals that are currently FDA-approved and medically necessary in prostate cancer are: ^{68}Ga PSMA-11 (UCSF & UCLA), ^{18}F Piflufolastat (Pylarify®), ^{18}F Flotufolastat (Posluma®), and ^{68}Ga Gozetotide (Illuccix®, Locametz®, and Gozellix®).
- While early detection of low-volume recurrence after treatment of prostate cancer using PET/CT scans may influence therapeutic decisions, there is lack of evidence that this approach has any meaningful impact on overall survival.
- As high-intensity focused ultrasound prostate ablation is considered investigational and experimental at this time, advanced imaging for treatment planning and/or

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

surveillance of high intensity focused ultrasound prostate ablation is not medically necessary.
- MR Spectroscopy (CPT® 76390) is considered not medically necessary in the evaluation of prostate cancer at this time.
- As laser prostate ablation is considered investigational and experimental at this time, advanced imaging for treatment planning and/or surveillance of laser prostate ablation is not medically necessary.
- Monitoring an elevated prostate-specific antigen level (PSA) with serial MRI is not medically necessary for suspected prostate cancer.
- Requests for imaging based on PSA must provide a recent PSA.

ISUP Prostate Cancer Grade Groups

Grade Group	Gleason Score	Gleason Pattern
1	≤6	≤3+3
2	7	3+4
3	7	4+3
4	8	4+4, 3+5, 5+3
5	9 or 10	4+5, 5+4, or 5+5

NCCN Initial Risk Stratification
- Low Risk
  - ALL of the following features are present:
    - Clinical T Stage = cT1-cT2a (palpable tumor limited to ≤1/2 of one side)
    - PSA (ng/mL) <10
    - Gleason Grade Group = 1
- Intermediate Risk
  - No "high-risk" or "very high-risk" features and one or more of the following intermediate risk factors (IRFs):
    - cT2b-cT2c
    - Grade group 2 or 3
    - PSA 10-20 ng/mL
  - Favorable Intermediate Risk
    - ALL of the following features must be present:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

        - Only 1 IRF
        - Gleason Grade Group = 1 or 2
        - <50% biopsy cores positive (e.g., <6 of 12 cores)
    - Unfavorable Intermediate Risk
        - One or more of the following must be present:
            - 2 or 3 IRFs
            - Gleason grade group = 3
            - ≥50% biopsy cores positive (e.g., ≥6 of 12 cores)
- High-Risk
    - ONE or more of the following high-risk features is present:
        - Clinical T Stage = cT3-cT4
        - PSA (ng/mL) >20
        - Gleason Grade Group = 4 or 5
- Very High-Risk
    - At least TWO of the following features is present:
        - Clinical T stage = cT3-cT4 (extension into the seminal vesicles or invasion into adjacent structures)
        - Primary Gleason Pattern = 5
        - Gleason Grade Group = 4 or 5
        - PSA (ng/mL) >40

3D Rendering of MRI for MRI / Ultrasound Fusion Biopsy:

- When specific target lesion(s) is (are) detected on multi-parametric MRI (mpMRI) prostate and classified as PIRADS 3, 4, or 5, 3D Rendering (CPT® 76377) to generate prostate segmentation data image set for target identification on MRI/ Transrectal ultrasound (TRUS) fusion biopsy is medically necessary as:
    - a subsequent separate standalone request; or
    - a retrospective request for medical necessity
- For MRI/TRUS fusion biopsy of a PIRADS 1-2 lesion, approval of 3D rendering at independent workstation (CPT® 76376 or CPT® 76377) can be considered on a case-by-case basis.
- If there is no target lesion identified on MRI, then 3D rendering and MRI/TRUS fusion biopsy is generally not medically necessary.
- The 3D rendering for the TRUS component of the fusion is a part of the UroNav Fusion Equipment Software and an additional 3D code CPT® 76376 or CPT® 76377 is not medically necessary.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion

Screening can begin as early as age 40 for high-risk individuals (Black/African American identity, certain germline mutations, or concerning family history) and 45 for individuals with average risk. Those with a first-degree relative diagnosed at age less than 60 years have a more than 2-fold increase in likelihood of prostate cancer diagnosis. Individuals with Black/African American identity have a 60% higher incidence of prostate cancer. Individuals with high-risk adverse clinical and pathologic factors may benefit from a more aggressive diagnostic and therapeutic approach at the time of relapse after initial treatment.[2]

Suspected Prostate Cancer (ONC-19.1)

ON.PR.0019.1.A
v3.0.2026

Indication	Medically Necessary Imaging Study
ANY of the following: • Age 40-44 years with PSA >3 ng/ml or very suspicious DRE and ONE of the following high-risk features: ◦ Black/African American identity ◦ Germline mutations that increase the risk of prostate cancer ◦ Family history of first- or second-degree relative with prostate, male breast, pancreatic, or ovarian cancer ◦ Family history of two or more first-degree relatives diagnosed at any age with colorectal, endometrial, breast, or prostate cancer ◦ Family history of first- or second-degree relative diagnosed at age ≤45 years with female breast cancer ◦ Family history of first- or second-degree relative diagnosed at age ≤50 years with colorectal or endometrial cancer • Age 45-75 years and ONE of the following: ◦ PSA >3ng/ml ◦ Very suspicious DRE • Age >75 years and ONE of the following: ◦ PSA ≥4ng/ml ◦ Very suspicious DRE • At least one negative/non-diagnostic TRUS biopsy and ANY of the following: ◦ Rising PSA ◦ Abnormal DRE ◦ Need for confirmatory MR/US fusion biopsy	ANY of the following: • Transrectal ultrasound (CPT® 76872) • TRUS-guided biopsy (CPT® 76942) • MRI/US fusion biopsy (CPT® 76942) • MRI Pelvis without and with contrast (CPT® 72197) or without contrast (CPT® 72195)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
• PIRADS 3, 4, or 5 lesion identified on recent diagnostic MRI Pelvis (CPT® 72195 or CPT® 72197) and planning for biopsy to be done by MRI/TRUS fusion technique	• 3D Rendering (CPT® 76376 or CPT® 76377)
ANY of the following: • Multifocal (2 or more lesions) high-grade prostatic intraepithelial neoplasia (PIN) • Atypia on biopsy	• Extended pattern re-biopsy within 6 months by TRUS-guided biopsy (CPT® 76942)
• Solitary PIN (1 lesion)	ONE of the following, to be repeated in one year: • MRI Pelvis without contrast (CPT® 72195) • MRI Pelvis without and with contrast (CPT® 72197) • MRI/US fusion biopsy (CPT® 76942 or 76872) ◦ These codes are medically necessary in addition to MR Pelvis codes above, if requested
In office, transperineal, MRI guided biopsy without US fusion (i.e., ProMaxo)	Neither MRI CPT® 77021 nor 76498 are medically necessary in conjunction with procedure codes (see: **CT-, MR-, or US-Guided Procedures (Preface-4.2)**). MRI is bundled in with the procedure code.
An existing MRI cannot be used for MRI/US fusion biopsy	Unlisted MRI code (CPT® 76498)

Evidence Discussion

Based on the high-risk factors outlined above along with age, digital rectal exam (DRE) findings and PSA level, further imaging work-up may be medically necessary to include transrectal ultrasound with or without biopsy, MRI of the pelvis without and/or with

Indication	Medically Necessary Imaging Study
To confirm oligo- or low volume metastatic prostate cancer suspected on conventional imaging in individuals with biopsy-proven prostate cancer	• PSMA PET/CT (CPT® 78815 or CPT® 78816) or PSMA PET/MRI (CPT® 78813 and CPT® 76498) with any of the following radiotracers: ◦ ^{68}Ga-PSMA-11 ◦ ^{18}F Piflufolastat (Pylarify®) ◦ ^{18}F Flotufolastat (Posluma®) ◦ ^{68}Ga Gozetotide (Illuccix®, Locametz®, and Gozellix®)
Known diffuse metastatic prostate cancer (including prior to prostate biopsy) (In obvious diffuse metastatic prostate cancer based on other imaging, PSMA PET is not medically necessary)	Any ONE of the following combinations, not all: • CT Chest with contrast (CPT® 71260), CT Abdomen and Pelvis with contrast (CPT® 74177), and Bone scan (CPT® 78306) • CT Chest with contrast (CPT® 71260), CT Abdomen with contrast (CPT® 74160), MRI Pelvis without and with contrast (CPT® 72197) if not previously performed, and Bone scan (CPT® 78306) (see: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Inconclusive bone scan	Any ONE of the following: • CT with contrast of involved body site • MRI without and with contrast of involved body site • PET/CT (CPT® 78815 or CPT® 78816) or PET/MRI (CPT® 78813 and CPT® 76498) using any one of the following radiotracers: ◦ ^{18}F Fluciclovine ◦ ^{11}C Choline ◦ ^{68}Ga-PSMA-11 ◦ ^{18}F Piflufolastat (Pylarify®) ◦ ^{18}F Flotufolastat (Posluma®) ◦ ^{68}Ga Gozetotide (Illuccix®, Locametz®, and Gozellix®) ◦ ^{18}F sodium fluoride

At present, neither the AUA guidelines nor NCCN guidelines consider cribriform histology and/or perineural invasion as standalone risk factors that move individuals into an unfavorable intermediate risk or higher group.

Evidence Discussion

Risk stratification uses a minimum of stage, Gleason grade, and PSA to assign individuals to risk groups that in turn help select the imaging options and predict the probability of biochemical recurrence after definitive local therapy. The current prostate cancer grading system was adopted from the ISUP 2014 consensus conference with the goal to limit overtreatment. The grading system is divided into 5 risk groups.

The goal of imaging is to detect and characterize disease in order to guide disease management. Low risk and favorable intermediate risk does not routinely require advanced imaging. NCCN stated that "conventional bone scans are rarely positive in asymptomatic individuals with PSA <10 ng/mL".[1] Low risk and favorable intermediate risk groups have very low risk of positive bone scan or CT scan.[1]

Unfavorable intermediate risk, high-risk, and very high-risk do require imaging that can be a combination of CT/MRI Pelvis or PSMA PET using specific radiotracers. In individuals with known or suspected metastatic disease, CT Chest, Abdomen, and Pelvis along with bone scan are medically necessary. MRI Pelvis is an acceptable

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

choice in lieu of CT Pelvis due to MRI's ability to provide detailed soft tissue characterization and contrast. NCCN supported bone imaging for those at high risk for skeletal metastases[1]

For inconclusive bone findings, NCCN stated that additional imaging using CT, MRI, PSMA-PET/CT or PSMA-PET/MRI, or PET/CT or PET/MRI with F-18 sodium fluoride, C-11 choline, or F-18 fluciclovine can be considered. For conventional imaging suggesting oligo- or low-volume metastatic disease, PET/CT using specific radiotracers can be performed to confirm the individual is a candidate for localized treatment. F18-FDG PET/CT scans are considered not medically necessary for evaluation of prostate cancer because, per NCCN, there is a lack of data surrounding the use of this radiotracer in individuals with prostate cancer. Other radiotracers (C11 choline, F18-Fluciclovine, PSMA-specific) are FDA approved and have influenced treatment planning, but the impact on long-term survival remains to be studied. However, data does indicate that PSMA-PET has a high sensitivity for metastatic disease and small-volume disease compared to conventional imaging, and therefore, it has become a useful tool for the evaluation of individuals with prostate cancer. The NCCN and AUA stated that PSMA PET may offer additional sensitivity and specificity over conventional imaging; therefore, if conventional imaging is performed as first line and there is continued suspicion of extraprostatic disease despite a negative or inconclusive study, PSMA PET may be performed.[1]

Prostate Cancer – Restaging/Recurrence (ONC-19.3)

ON.PR.0019.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
For ANY of the following: • Obvious progression by DRE with plans for prostatectomy or radiation therapy • Repeat TRUS biopsy for rising PSA shows progression to a higher Gleason's score with plans for prostatectomy or radiation therapy • Inconclusive findings on CT scan	• MRI Pelvis without and with contrast (CPT® 72197)
Non-metastatic prostate cancer previously treated with ablation, hormonal therapy, or chemotherapy **and** any one of the following: • Clinical suspicion of relapse/recurrence • Palpable anastomotic recurrence • PSA rises above post-treatment baseline to >0.2ng/mL on two consecutive measurements	Any ONE of the following combinations (may be obtained in addition to mpMRI Prostate): • CT Chest with contrast (CPT® 71260), CT Abdomen and Pelvis with contrast (CPT® 74177), and Bone scan (CPT® 78306) (see: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes) • CT Chest with contrast (CPT® 71260), CT Abdomen with contrast (CPT® 74160), MRI Pelvis without and with contrast (CPT® 72197), and Bone scan (CPT® 78306) (see: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Non-metastatic prostate cancer previously treated with prostatectomy and **all** of the following are met: • Persistent detectable PSA after prostatectomy, or • Undetectable PSA that subsequently becomes detectable with two consecutive increases in PSA (to any amount), or • Any increase in PSA to 0.1 ng/mL or higher	Any ONE of the following: • PSMA PET/CT scan (CPT® 78815 or CPT® 78816) or PET/MRI (CPT® 78813 and CPT® 76498) with any of the following radiotracers: ◦ ^{68}Ga-PSMA-11 ◦ ^{18}F Piflufolastat (Pylarify®) ◦ ^{18}F Flotufolastat (Posluma®) ◦ ^{68}Ga Gozetotide (Illuccix®, Locametz®, and Gozellix®) • CT Chest with contrast (CPT® 71260), CT Abdomen and Pelvis with contrast (CPT® 74177), and Bone scan (CPT® 78306) (see: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes) • CT Chest with contrast (CPT® 71260), CT Abdomen with contrast (CPT® 74160), MRI Pelvis without and with contrast (CPT® 72197), and Bone scan (CPT® 78306) (see: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes)

Proprietary Information of UnitedHealthcare.

Indication	Medically Necessary Imaging Study
Non-metastatic prostate cancer previously treated with radiation therapy and two consecutive increases in PSA above nadir	Any ONE of the following: • PSMA PET/CT scan (CPT® 78815 or CPT® 78816) or PET/MRI (CPT® 78813 and CPT® 76498) with any of the following radiotracers: ◦ ^{68}Ga-PSMA-11 ◦ ^{18}F Piflufolastat (Pylarify®) ◦ ^{18}F Flotufolastat (Posluma®) ◦ ^{68}Ga Gozetotide (Illuccix®, Locametz®, and Gozellix®) • CT Chest with contrast (CPT® 71260), CT Abdomen and Pelvis with contrast (CPT® 74177), and Bone scan (CPT® 78306) (see: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes) • CT Chest with contrast (CPT® 71260), CT Abdomen with contrast (CPT® 74160), MRI Pelvis without and with contrast (CPT® 72197), and Bone scan (CPT® 78306) (see: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes)
Non-metastatic prostate cancer previously treated with prostatectomy or radiation therapy, and **all** of the following are met: • PSA rises on two consecutive measurements above post-treatment baseline **and** • PSA ≥1 ng/mL **and** • Recent CT scan and bone scan are negative for metastatic disease	• PET/CT scan (CPT® 78815 or CPT® 78816) or PET/MRI (CPT® 78813 and CPT® 76498) using any **ONE** of the following radiotracers: ◦ ^{18}F-Fluciclovine ◦ ^{11}C Choline

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Suspected progression of known metastatic disease based on: • New or worsening signs/symptoms • Rising PSA levels	• CT Chest with contrast (CPT® 71260), CT Abdomen and Pelvis with contrast (CPT® 74177), and Bone scan (CPT® 78306) (see: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes) • CT with contrast of any involved or symptomatic body part
Metastatic prostate cancer receiving treatment with chemotherapy or Pluvicto®	One of the following combinations, every 2 cycles (6 to 8 weeks), while on chemotherapy: • CT Abdomen and Pelvis with contrast (CPT® 74177) and CT scan with contrast of any involved body part • CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250) OR • CT Abdomen with contrast (CPT® 74160), MRI Pelvis without and with contrast (CPT® 72197) AND, every 3-6 months: • Bone scan (CPT® 78306) (see: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes) Restaging PSMA and/or SPECT/CT is not medically necessary in the absence of equivocal conventional imaging

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Metastatic prostate cancer receiving anti-androgen therapy	One of the following combinations, every 3 months, while on anti-androgen therapy: • CT Abdomen and Pelvis with contrast (CPT® 74177) and CT scan of any involved body part • CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250) OR • CT Abdomen with contrast (CPT® 74160), MRI Pelvis without and with contrast (CPT® 72197) AND, every 3-6 months: • Bone scan (CPT® 78306) (see: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Active metastatic prostate cancer with evidence of progression (clinical/ PSA/conventional imaging) and being considered for ^{177}Lu-PSMA-617 (Pluvicto®) treatment	ANY or ALL of the following: • PSMA PET/CT scan (CPT® 78815 or CPT® 78816) or PET/MRI (CPT® 78813 and CPT® 76498) with one of the following agents: ◦ ^{68}Ga PSMA-11 ◦ ^{18}F Piflufolastat (Pylarify®) ◦ ^{68}Ga Gozetotide (Illucix®, Locametz®, and Gozellix®) ◦ ^{18}F Flotufolastat (Posluma®) • The combination of: ◦ CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250), CT Abdomen with contrast (CPT® 74160), MRI Pelvis without and with contrast (CPT® 72197), and Bone scan (CPT® 78306) (see: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes) **OR** ◦ CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250), CT Abdomen and Pelvis with contrast (CPT® 74177), and Bone scan (CPT® 78306) (see: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes) *While PSMA PET is medically necessary to determine candidacy for Pluvicto®, it is not medically necessary for restaging on Pluvicto®; thus, baseline conventional imaging is medically necessary in addition to baseline PSMA PET/CT or PET/MRI.

Indication	Medically Necessary Imaging Study
Non-metastatic prostate cancer treated with prostatectomy or radiation therapy who do not meet ALL above criteria for PSMA PET/CT but have clinical signs/ symptoms of recurrence	Any ONE of the following combinations: • CT Chest with contrast (CPT® 71260), CT Abdomen and Pelvis with contrast (CPT® 74177), and Bone scan (CPT® 78306) (see: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes) • CT Chest with contrast (CPT® 71260), CT Abdomen with contrast (CPT® 74160), MRI Pelvis without and with contrast (CPT® 72197), and Bone scan (CPT® 78306) (see: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes)
Prior to start of Xofigo® (Radium-223) therapy	• ONE time CT Chest, Abdomen, and Pelvis with contrast (CPT® 71260 and CPT® 74177)
Inconclusive bone scan	Any ONE of the following: • CT with contrast of involved body site • MRI without and with contrast of involved body site • PET/CT (CPT® 78815 or CPT® 78816) or PET/MRI (CPT® 78813 and CPT® 76498) using any one of the following radiotracers: ◦ ^{18}F Fluciclovine ◦ ^{11}C Choline ◦ ^{68}Ga-PSMA-11 ◦ ^{18}F Piflufolastat (Pylarify®) ◦ ^{18}F Flotufolastat (Posluma®) ◦ ^{68}Ga Gozetotide (Illuccix®, Locametz®, and Gozellix®) ◦ ^{18}F sodium fluoride

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Conventional imaging studies (CT and bone scan) suggests oligo- or low volume metastatic disease that needs further confirmation	• PET/CT scan (CPT® 78815 or CPT® 78816) or PET/MRI (CPT® 78813 and CPT® 76498) using any one of the following radiotracers: ◦ ^{18}F Fluciclovine ◦ ^{11}C Choline ◦ ^{68}Ga-PSMA-11 ◦ ^{18}F Piflufolastat (Pylarify®) ◦ ^{68}Ga Gozetotide (Illuccix®, Locametz®, and Gozellix®) ◦ ^{18}F Flotufolastat (Posluma®)

Evidence Discussion

The use of PSMA PET radiotracers has been shown to impact treatment planning, but more research is needed on the impact to long-term outcomes. However, the benefit to individuals of initiating treatment earlier for recurrent disease detected on PSMA PET outweighs the disadvantages of possible false-positives. For non-metastatic prostate cancer previously treated with prostatectomy, NCCN stated that PET can be used without prerequisite conventional imaging for suspected biochemical recurrence. This recommendation is due to "increased sensitivity and specificity of PSMA-PET tracers for detecting micrometastatic disease compared to conventional imaging". Conventional imaging is also noted as useful for workup of recurrence or progression. For individuals treated with radiation therapy, NCCN stated that suspected recurrence can also be imaged using these modalities. In the setting of distant metastatic disease, CT imaging along with bone scan is the mainstay of imaging with PET/CT reserved for inconclusive conventional imaging or oligo-/low volume disease that needs confirmation. NCCN stated "CT provides a high level of anatomic detail, and may detect gross extracapsular disease, nodal metastatic disease, and/or visceral metastatic disease." PSMA imaging at baseline is medically necessary for individuals being considered for 177Lu-PSMA-617 (Pluvicto®) treatment. The NCCN and AUA support PSMA PET to establish candidacy for Pluvicto® in the setting of metastatic prostate cancer without a requirement for additional conventional imaging. For restaging of patients on or following treatment with Pluvicto®, conventional imaging remains the standard of care, with other modalities as support for inconclusive bone scan. While there is emerging data regarding use of SPECT/CT for restaging on therapy with Pluvicto®, neither the NCCN nor AUA nor SNMMI provide guidance for its use in routine restaging in this setting.[1]

Prostate Cancer – Follow-up On Active Surveillance (ONC-19.4)

ON.PR.0019.4.A
v3.0.2026

Active surveillance is being increasingly utilized in prostate cancer, and this therapeutic option involves regimented monitoring of an individual with known diagnosis of low-risk prostate cancer for disease progression, without specific anticancer treatment. While being treated with active surveillance, an individual is generally considered a potential candidate for curative intent treatment approaches in the event that disease progression occurs.

It is important to distinguish active surveillance from watchful waiting (or observation), which is generally employed in individuals with limited life expectancy. Watchful waiting involves cessation of routine monitoring and treatment is initiated only if symptoms develop.

Current active surveillance guidelines suggest the following protocol:

- PSA every 6 months
- Digital Rectal Exam (DRE) every 12 months
- Repeat prostate biopsy every 12 months
- Repeat mpMRI (CPT® 72195 or CPT® 72197) no more often than every 12 months

Indication	Medically Necessary Imaging Study
Routine monitoring on active surveillance protocol	• MRI Pelvis without (CPT® 72195) or without and with contrast (CPT® 72197) at initiation of active surveillance, and every 12 months thereafter
Planning for re-biopsy to be done by MRI/US fusion technique	• 3D Rendering (CPT® 76376 or CPT® 76377)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
For ANY of the following: • Progression is suspected based on DRE changes or rising PSA and a recent TRUS biopsy was negative • Repeat TRUS biopsy shows progression to a higher Gleason score	• MRI Pelvis without (CPT® 72195) or MRI Pelvis without and with contrast (CPT® 72197)
Individuals on active surveillance who are noted to have progression and have plans to initiate treatment	• Imaging studies for initial staging as per **ONC-19.2**

Evidence Discussion

For certain individuals who fall into a low-risk category, close monitoring in the absence of treatment can be pursued with the intent to offer curative therapy in the event progression occurs. Current guidelines include PSA every 6 months, DRE every 12 months, repeat prostate biopsy every 12 months and repeat mpMRI no more often than every 12 months. NCCN stated that a metastatic staging evaluation is not medically necessary for those on active surveillance. With progression and the decision to pursue treatment, imaging is performed according to the same principles as stated in initial staging.[1]

Surveillance/Follow-up For Treated Prostate Cancer (ONC-19.5)

ON.PR.0019.5.A
v3.0.2026

Indication	Medically Necessary Imaging Study
ANY of the following: • Asymptomatic or stable chronic symptoms • Stable DRE findings • Stable PSA levels	• Advanced imaging is not routinely medically necessary for surveillance

Evidence Discussion

For individuals who are asymptomatic or have chronic stable findings to include DRE and PSA, advanced imaging is not medically necessary. This form of monitoring is also referred to as observation. NCCN stated that the advantages of observation include the avoidance of "possible side effects of unnecessary confirmatory testing and definitive therapy".[1]

Testicular, Ovarian and Extragonadal Germ Cell Tumors – General Considerations (ONC-20.0)

ON.TO.0020.0.A

v3.0.2026

- This section applies to primary germ cell tumors occurring outside the central nervous system for individuals aged >15 years at the time of initial diagnosis. Individuals aged ≤15 years at diagnosis should be imaged according to pediatric guidelines in: **Pediatric Germ Cell Tumors (PEDONC-10)** in the Pediatric and Special Populations Oncology Imaging Guidelines.
- These guidelines are for germ cell tumors of the testicle, ovary and extragonadal sites as well as malignant sex cord stromal tumors.
- Requests for imaging must state the histologic type of the cancer being evaluated.
- Classified as seminoma/dysgerminoma, non-seminomatous germ cell tumors (NSGCT), or mixed.
  - Dysgerminoma is the ovarian equivalent of seminoma. There is no testicular dysgerminoma.
  - Mixed tumors are treated as NSGCTs, as they tend to be more aggressive.
  - Germ Cell Tumors include:
    - Teratomas
    - Yolk sac tumors
    - Choriocarcinomas
    - Embryonal carcinomas
    - Mixed germ cell tumors
    - Dysgerminoma
  - Sex Cord Stromal Tumors include:
    - Granulosa Cell Tumor (juvenile/adult)
    - Fibroma/Fibrosarcoma
    - Thecoma
    - Levdig Cell Tumor
    - Sertoli Cell Tumor
    - Mixed (Sertoli-Levdig, Gynadroblastoma)
- MRI in place of CT scans to reduce risk of secondary malignancy is not supported by the peer-reviewed literature. CT scans are medically necessary for surveillance and are the preferred modality of imaging to assess for recurrence.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- PET/CT is considered not medically necessary for evaluation of non-seminomatous germ cell tumors.
- Active surveillance in testicular cancer refers to treatment with surgery (orchiectomy) alone without any additional post-operative treatment such as chemotherapy or radiotherapy.

Testicular, Ovarian and Extragonadal Germ Cell Tumors – Initial Work-Up/ Staging (ONC-20.1)

ON.TO.0020.1.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Suspicious testicular mass or ovarian mass with concern for metastatic disease on ultrasound • For all other ovarian masses prior to tissue diagnosis, see **Complex Adrenal Masses (PV-5.3)**	EITHER of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) or • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)
After orchiectomy or oophorectomy: • Orchiectomy/oophorectomy is both diagnostic and therapeutic, and imaging was not performed prior to surgery OR • Individual is Stage IS (i.e., has persistently elevated tumor markers)	EITHER of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) or • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)
Prior to initiation of chemotherapy to confirm staging, if prior imaging was performed ≥4 weeks ago	Repeat abdominal imaging with ONE of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) or • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
For ANY of the following: • Testicular non-seminoma histology • Any ovarian germ cell tumor • Abdominal lymphadenopathy noted on CT scan • Abnormal chest x-ray or signs/ symptoms suggestive of chest involvement • Individual is Stage IS (i.e., has persistently elevated tumor markers)	In addition to the above abdominal/pelvic imaging: • CT Chest with contrast (CPT® 71260)
Individual is Stage IS (i.e., has persistently elevated tumor markers)	In addition to the above, scrotal ultrasound (CPT® 76856 or CPT® 76857) to assess for a contralateral testis mass if one has not been conducted in the last 3 months
Prior surgery with incomplete staging for ovarian germ cell tumors	EITHER of the following: • CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) or • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)
Inconclusive conventional imaging for ovarian germ cell tumors	PET/CT (CPT® 78815) or PET/MRI (CPT® 78813 and CPT® 76498)
Extragonadal Germ Cell Tumor	CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177)
Sex Cord Stromal Tumors	Once diagnosis confirmed, no imaging is medically necessary.

Evidence Discussion

- American Urological Association guideline recommended scrotal ultrasound with Doppler should be obtained in individuals with a unilateral or bilateral scrotal mass suspicious for neoplasm and that MRI should not be used in the initial evaluation and diagnosis of a testicular lesion suspected of being a neoplasm.[12]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Ultrasound requires no ionizing radiation and is readily available. Overall, ultrasound is relatively quick and non-invasive modality to evaluate a testicular lesion. There are relatively few disadvantages of ultrasound for testicular lesions and primarily relate to sonographer experience.
- As advanced imaging modalities, CT and MRI offer excellent 3-D resolution. A CT scan can require a significant dose of ionizing radiation, but the speed of image acquisition reduces the potential for motion artifact. MRI yields better soft contrast resolution than CT and does not expose individuals to ionizing radiation, but due to longer image time is motion artifact-prone and may require sedation.

Seminoma

- NCCN recommended CT of the abdomen and pelvis with contrast or MRI of the abdomen and pelvis with and without contrast, and a chest x-ray. Chest CT with contrast is recommended if there is a positive finding on abdomen CT or abnormal chest x-ray.[1]

Nonseminoma

- NCCN recommended CT of the abdomen, pelvis and chest with contrast or MRI of the abdomen and pelvis with and without contrast in addition to a chest CT with contrast.[1]

Testicular, Ovarian and Extragonadal Germ Cell Tumors – Restaging/ Recurrence (ONC-20.2)

ON.TO.0020.2.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Treatment response for individuals with measurable disease or persistent elevated tumor markers, every 2 cycles	• CT Abdomen and Pelvis with contrast (CPT® 74177) OR • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) AND • CT with contrast of previously involved body areas
For any of the following • At end of adjuvant therapy ◦ Any stage embryonal tumor ◦ Any stage endodermal sinus tumor (i.e., yolk sac tumor) ◦ Stage II-IV dysgerminoma ◦ Stage I, Grade 2 or 3 immature teratoma ◦ Any grade, Stage II-IV immature teratoma ◦ Any stage non-gestational choriocarcinoma • During adjuvant therapy only for signs and symptoms of disease progression	EITHER of the following: • CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) or • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) ◦ If inconclusive, PET/CT (CPT® 78815) or PET/MRI (CPT® 78813 and CPT® 76498)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Seminoma with residual mass >3cm after completion of chemotherapy	• PET/CT (CPT® 78815) ◦ If PET/CT is positive, biopsy or resection should be considered ◦ If biopsy or resection is not performed, PET/CT may be repeated once in 6-12 weeks
Nonseminoma or pure seminoma with partial response or with residual mass and ALL of the following: • Abnormal AFP or beta-hCG levels • Need to evaluate for occult brain metastases	• MRI Brain without and with contrast (CPT® 70553)
Stage IIA pure seminoma or stage IIA nonseminoma with borderline retroperitoneal lymph nodes on preoperative imaging, 4-8 weeks after preoperative imaging	ONE of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) or • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)
End of therapy evaluation for NSGCT post chemotherapy or post retroperitoneal lymph node dissection (RPLND)	• CT Abdomen and Pelvis with contrast (CPT® 74177)
Recurrence suspected, including increased tumor markers	• CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast • Ultrasound (CPT® 76856 or CPT® 76857) of the remaining gonad if applicable
Unexplained pulmonary symptoms despite a negative chest x-ray, or new findings on chest x-ray	• CT Chest with contrast (CPT® 71260)
Sex cord stromal tumors with elevated inhibin or signs and symptoms of recurrence	• CT Chest with contrast (CPT® 71260) AND one of the following: ◦ CT Abdomen and Pelvis (CPT® 74177) OR ◦ MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Evidence Discussion

In individuals with pure seminoma with a residual mass >3cm post-primary chemotherapy, PET/CT is medically necessary. If this PET/CT scan is positive, biopsy or resection should be considered. An alternative option, if biopsy is not performed, is to wait an additional 6-12 weeks and repeat PET/CT to assess for any changes. If the mass is persistently positive, biopsy or resection is recommended.[1]

Testicular, Ovarian and Extragonadal Germ Cell Tumors – Surveillance (ONC-20.3)

ON.TO.0020.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Stage I seminoma treated with orchiectomy alone (no radiotherapy or chemotherapy, also called active surveillance)	ONE of the following, every 4 months in year 1, then every 6 months for years 2 and 3, and then annually until year 5: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen with contrast (CPT® 74160) • MRI Abdomen without and with contrast (CPT® 74183) • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)
Stage I seminoma treated with radiotherapy and/or chemotherapy	ONE of the following, annually for 3 years: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen with contrast (CPT® 74160) • MRI Abdomen without and with contrast (CPT® 74183) • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Stage IIA and non-bulky stage IIB seminomas treated with radiotherapy or chemotherapy	ONE of the following, once at 3 months, then once at 9-12 months after completion of therapy, then annually for 2 additional years: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen with contrast (CPT® 74160) • MRI Abdomen without and with contrast (CPT® 74183) • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)
Stage II seminoma treated with primary RPLND and NOT treated with adjuvant chemotherapy	ONE of the following, every 4 months in year 1, every 6 months in year 2, and annually in year 3: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen with contrast (CPT® 74160) • MRI Abdomen without and with contrast (CPT® 74183) • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)
Stage II seminoma treated with primary RPLND AND adjuvant chemotherapy	ONE of the following, at 6 months, 12 months, and 24 months: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen with contrast (CPT® 74160) • MRI Abdomen without and with contrast (CPT® 74183) • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Bulky stage IIB, IIC, and III seminomas treated with chemotherapy	For individuals with ≤3cm residual mass, ONE of the following every 4 months for 1 year, every 6 months for 1 year, and then annually for 2 additional years: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen with contrast (CPT® 74160) • MRI Abdomen without and with contrast (CPT® 74183) • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) For individuals with >3cm residual mass and negative PET scan, ONE of the following at 6 and 12 months after completion of therapy, then annually until year 5: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen with contrast (CPT® 74160) • MRI Abdomen without and with contrast (CPT® 74183) • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) For individuals with thoracic disease: • CT Chest with contrast (CPT® 71260) every 2 months for 1 year, then every 3 months for 1 year, then annually until year 5 after completion of therapy

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Stage IA non-seminomatous germ cell tumors treated with orchiectomy alone (without risk factors)	ONE of the following, every 4 months for one year, every 6 months in the second year, and then annually for years 3, 4, and 5: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen with contrast (CPT® 74160) • MRI Abdomen without and with contrast (CPT® 74183) • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) • Scrotal ultrasound (CPT® 76856 or CPT® 76857) to assess for a contralateral testis mass if one has not been conducted in the last 3 months
Stage IB non-seminomatous germ cell tumors treated with orchiectomy alone (with risk factors – lymphovascular invasion or invasion into spermatic cord/scrotum)	ONE of the following, every 4 months for years 1 and 2, then every 6 months for year 3, and then once in year 4: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen with contrast (CPT® 74160) • MRI Abdomen without and with contrast (CPT® 74183) • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) • Scrotal ultrasound (CPT® 76856 or CPT® 76857) to assess for a contralateral testis mass if one has not been conducted in the last 3 months

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Stage IA/IB non-seminomatous germ cell tumors treated with chemotherapy and/or primary RPLND	ONE of the following, annually for 2 years: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen with contrast (CPT® 74160) • MRI Abdomen without and with contrast (CPT® 74183) • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) • Scrotal ultrasound (CPT® 76856 or CPT® 76857) to assess for a contralateral testis mass if one has not been conducted in the last 3 months
Stage II-III non-seminomatous germ cell tumors with complete response to chemotherapy +/- post-chemotherapy RPLND	ONE of the following, every 4 months in year 1, every 6 months in year 2, and then annually in year 3: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen with contrast (CPT® 74160) • MRI Abdomen without and with contrast (CPT® 74183) • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) For individuals with known thoracic disease or thoracic symptoms, every 4 months in year 1, every 6 months in year 2, then annually until year 4 after completion of therapy: • CT Chest with contrast (CPT® 71260)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Stage IIA, IIB, or IIC non-seminomatous germ cell tumors treated with post-primary RPLND AND adjuvant chemotherapy	ONE of the following, once at 3-4 months after completion of RPLND: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen with contrast (CPT® 74160) • MRI Abdomen without and with contrast (CPT® 74183) • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)
Stage IIA or IIB non-seminomatous germ cell tumors treated with post-primary RPLND WITHOUT adjuvant chemotherapy	ONE of the following, once at 4 months after completion of therapy and once in year 2: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen with contrast (CPT® 74160) • MRI Abdomen without and with contrast (CPT® 74183) • MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)
All ovarian germ cell tumors	• CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) every 3 months for 2 years, every 6 months for an additional year, and then after year 3, only for signs and symptoms of recurrence
• Sex cord stromal tumors (male and female) • Mature teratoma	• No routine advanced imaging is medically necessary for surveillance. • For symptoms, elevated biomarkers, or suspicious findings on physical exam, see **Testicular, Ovarian and Extragonadal Germ Cell Tumors - Restaging/Recurrence (ONC-20.2)** for suspected recurrence.
Extragonadal germ cell tumors	• CT of the involved region every 3 months for one year and every 6 months for one year

Proprietary Information of UnitedHealthcare.

Evidence Discussion

Pure seminoma:[1,13-16]

- Chest radiography is sufficient when compared with CT for follow-up of stage 1 pure seminoma and is recommended by NCCN. While CT is more sensitive than radiography for detecting recurrent disease in the chest, this added sensitivity is offset by lower specificity and a higher false positive detection rate for abnormalities that are not metastatic.
- Scrotal US does not have a role in the restaging of men with testicular cancer that has been established by orchiectomy, unless there is concern for contralateral tumor or equivocal clinical exam.
- CT Abdomen and Pelvis is the reference standard imaging test used for assessing the retroperitoneum. It is rapid, reproducible, and provides excellent imaging of the para-aortic and paracaval regions but does expose individuals to significant ionizing radiation.
- MRI of the abdomen and pelvis
  - MRI has comparable accuracy with CT for the detection of metastatic retroperitoneal lymph nodes and has the benefit of no ionizing radiation. The disadvantage of MRI is longer imaging time which can lead to motion artifact.
- CT of the abdomen and pelvis is the standard imaging test used for assessing the retroperitoneum for nodal metastasis but does expose the individual to high levels of ionizing radiation.
- NCCN guidelines recommended chest radiography for the surveillance of stage I nonseminomatous testicular cancer but chest CT with contrast is preferred in the presence of thoracic symptoms.

Nonseminoma:[1]

- CT of the abdomen and pelvis is the standard imaging test used for assessing the retroperitoneum for nodal metastasis but does expose the individual to high levels of ionizing radiation.
- NCCN guidelines recommended chest radiography for the surveillance of stage 1 nonseminomatous testicular cancer but chest CT with contrast is preferred in the presence of thoracic symptoms.
- MRI of the abdomen and pelvis shows comparable accuracy with CT in the detection of metastatic retroperitoneal lymph nodes and does not have high levels of ionizing radiation but is subject to motion artifact due to longer imaging time.
- Scrotal US does not have a role in the restaging of men with testicular cancer that has been established by orchiectomy, unless there is concern for contralateral tumor or equivocal clinical exam.

Ovarian Cancer – General Considerations (ONC-21.0)

ON.OC.0021.0.A

v3.0.2026

- Ovarian cancers include: epithelial ovarian cancers, ovarian cancers of low malignant potential and mixed Müllerian tumors, primary peritoneal and fallopian tube cancers.
  - There are five main types of epithelial ovarian cancers:
    - High-grade serous carcinoma (HGSC) (70%)
    - Endometrioid carcinoma (EC) (10%)
    - Clear cell carcinoma (CCC) (10%)
    - Mucinous carcinoma (MC) (3%)
    - Low-grade serous carcinoma (LGSC) (<5%)
- Borderline tumors (formerly referred to as tumors of low malignant potential) usually have some feature of carcinoma when they recur.
- Fallopian tube and primary peritoneal are usually serous carcinoma.
- Germ cell tumors and sex cord stromal tumors (granulosa cell tumors), are imaged according to **Testicular, Ovarian and Extragonadal Germ Cell Cancer (ONC-20)**.

Screening for Ovarian Cancer (ONC-21.1)

ON.OC.0021.1.A
v3.0.2026

Indication	Medically Necessary Study
High-Risk Factors: • Family history of BRCA 1 or BRCA 2 mutations • Family history of ovarian cancer • Hereditary ovarian cancer syndrome that includes ovarian, breast, and/or endometrial and gastrointestinal cancers [Lynch II syndrome] in multiple members of two to four generations • Low parity • Decreased fertility • Delayed childbearing	• The use of advanced imaging for ovarian cancer screening is considered not medically necessary. • Genetic counseling is recommended for women with an increased-risk family history.
Known BRCA 1 or BRCA 2 mutation	• Transvaginal ultrasound (CPT® 76830), combined with CA-125 for ovarian cancer screening is medically necessary annually starting at age 30, until risk-reducing salpingo-oophorectomy is performed.

Evidence Discussion

According to ACR Appropriateness Criteria for ovarian cancer screening, any imaging in an average-risk individual is "usually not appropriate."[5]

There is much debate about the role of imaging in screening for ovarian cancer. This cancer has a low prevalence but is the leading cause of mortality in women in the United States. Average lifetime risk is 1.3%. There are factors that increase the risk such as family history, BRCA 1 or BRCA 2 mutations, nulliparity, lack of hormonal contraceptive use, and lack of breastfeeding. Genetic predisposition is associated with the highest increase in risk.

In individuals who are considered high-risk (personal or family history, genetic predisposition or elevated CA-125) ultrasound and color Doppler may be appropriate annual screening along with CA-125. Lu, et al. demonstrated a PPV 40% with specificity

Click Here to Return to the Main TOC

of 99.9% using ROCA.[11] Studies showed that the risk for developing ovarian cancer increases with age beginning around age 30 years.[12]

Click Here to Return to the Main TOC

Ovarian Cancer – Suspected/Diagnosis (ONC-21.2)

ON.OC.0021.2.A
v3.0.2026

- See: **Complex Adnexal Masses (PV-5.3)** for imaging guidelines for evaluation of suspected ovarian malignancies.
- To differentiate the origin of pelvic masses that are not clearly of ovarian origin, see: **Suspected Adnexal Mass (PV-5.1)**.
- Germ cell tumors and sex cord stromal tumors (granulosa cell tumors), are imaged according to **Testicular, Ovarian and Extragonadal Germ Cell Cancer (ONC-20)**.

Indication	Medically Necessary Imaging
• Pelvic signs or symptoms • Palpable pelvic mass	• Transvaginal (TV) ultrasound imaging (CPT® 76830) and/or Pelvic ultrasound (CPT® 76856 or CPT® 76857)
• Ultrasound shows complex and/or solid adnexal mass suspicious for ovarian malignancy or • Any suspicious signs/symptoms for ovarian malignancy (ascites, abdominal symptoms such as distension or tenderness, elevated CA-125, elevated LFTs, obstructive uropathy)	ANY of the following: • MRI Pelvis without and with contrast (CPT® 72197) ◦ MRI Pelvis without contrast (CPT® 72195) if contrast is contraindicated • CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ MRI Abdomen and MRI Pelvis without and with contrast (CPT® 74183 and CPT® 72197) are medically necessary in lieu of CT for individuals with renal insufficiency or contrast allergy. ◦ CT Abdomen and Pelvis without and with contrast (CT Urogram – CPT® 74178) only for symptoms of obstructive uropathy*

Evidence Discussion

If there is a question about the pelvic mass evaluation by ultrasound, transvaginal or pelvic ultrasound using O-RADS or IOTA is medically necessary to clarify risk before surgery. Accurate diagnosis of adnexal pathology is imperative in order to limit invasive interventions for benign lesions and improve preoperative triage to a gynecologic oncologist for high-risk lesions.[16] In order to standardize reporting of adnexal lesions,

Click Here to Return to the Main TOC

the American College of Radiology (ACR) has created the Ovarian-Adnexal Reporting and Data-System (O-RADS). A meta-analysis of 26 studies demonstrated that O-RADS has high sensitivity for detection of malignancy (95%).[16] A classification of O-RADS US Category 2 has an extremely low risk of malignancy (<1%), while a Category 5 has a high risk of malignancy (≥50%). For an indeterminate lesion on ultrasound or features concerning for malignancy, adjunct imaging with MRI is medically necessary to aid in preoperative triage. For individuals who have renal insufficiency and therefore are unable to undergo contrasted CT imaging of the abdomen and pelvis, the accepted substitute imaging is MRI with contrast.[1] This imaging will provide the necessary level of soft tissue detail that would not be achievable with a non-contrasted CT.

Ovarian Cancer – Initial Work-Up/Staging (ONC-21.3)

ON.OC.0021.3.A
v3.0.2026

- Germ cell tumors and sex cord stromal tumors (granulosa cell tumors), are imaged according to Testicular, Ovarian and Extragonadal Germ Cell Cancer (ONC-20).

Indication	Medically Necessary Imaging Study
Initial staging of all newly diagnosed ovarian cancer, if imaging has not yet been performed	• CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ MRI Abdomen and MRI Pelvis without and with contrast (CPT® 74183 and CPT® 72197) in lieu of CT for individuals with renal insufficiency or contrast allergy • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) for: ◦ Abnormal signs/symptoms of pulmonary disease ◦ Abnormal chest x-ray ◦ Concern for metastatic disease (i.e., elevated tumor markers, abdominal symptoms)
ANY of the following: • Primary peritoneal disease with biopsy-proven malignancy consistent with ovarian carcinoma • Elevated tumor markers with negative or inconclusive CT imaging	ONE of the following: • MRI Abdomen without and with contrast (CPT® 74183) and/or MRI Pelvis without and with contrast (CPT® 72197) OR • PET/CT (CPT® 78815)
If both CT and MRI are inconclusive	• PET/CT (CPT® 78815)
If CT, MRI, and PET/CT are inconclusive	• PET/MRI (CPT® 78813 and 76498)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion

If advanced imaging was not already performed, it is necessary to image the abdomen and pelvis with CT. NCCN stated that advanced imaging may improve assessment of metastases, staging, and preoperative planning.[1] For individuals who have renal insufficiency and therefore are unable to undergo contrasted CT imaging of the abdomen and pelvis, the preferred substitute imaging is MRI with contrast. This imaging will provide the necessary level of soft tissue detail that would not be achievable with a non-contrasted CT. For those with primary peritoneal disease or inconclusive or conflicting CT imaging, NCCN stated "MRI has been shown to provide equivalent accuracy for staging and comparable accuracy for predicting peritoneal tumor volume, and can be useful if CT results are inconclusive".[1] Chest imaging via CT either with or without contrast is necessary for suspected pulmonary disease or if there is concern for metastatic disease. NCCN stated this imaging is helpful to detect pleural or pulmonary metastases, as well as pleural effusion, which may help with treatment planning.[1] PET is a helpful tool in evaluation of indeterminate lesions on other imaging as it is shown to have high accuracy for detection of metastases.[1]

Click Here to Return to the Main TOC

Ovarian Cancer – Restaging/Recurrence (ONC-21.4)

ON.OC.0021.4.A
v3.0.2026

- Germ cell tumors and sex cord stromal tumors (granulosa cell tumors), are imaged according to Testicular, Ovarian and Extragonadal Germ Cell Cancer (ONC-20).

Indication	Medically Necessary Imaging Study
Completely resected or definitively treated with chemotherapy and normal(ized) tumor markers	• No advanced imaging is medically necessary
ANY of the following: • Unresected disease • Unknown preoperative markers • Difficult or abnormal examination • Elevated LFTs • Elevated tumor markers • Signs or symptoms of recurrence	• CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ MRI Abdomen and MRI Pelvis without and with contrast (CPT® 74183 and CPT® 72197) in lieu of CT for individuals with renal insufficiency or contrast allergy. • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) for ANY of the following: ◦ Known prior thoracic disease ◦ New or worsening pulmonary symptoms ◦ New or worsening chest x-ray findings ◦ Rising tumor markers
Monitoring response to treatment (every 2 cycles, or ~every 6 to 8 weeks)	• CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ MRI Abdomen and MRI Pelvis without and with contrast (CPT® 74183 and CPT® 72197) in lieu of CT for individuals with renal insufficiency or contrast allergy. • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) for ANY of the following: ◦ Known prior thoracic disease ◦ New or worsening pulmonary symptoms ◦ New or worsening chest x-ray findings

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
• CT negative or inconclusive and CA-125 continues to rise or elevated LFTs • Conventional imaging failed to demonstrate tumor or if persistent radiographic mass with rising tumor markers	ONE of the following: • MRI Abdomen and MRI Pelvis without and with contrast (CPT® 74183 and CPT® 72197) OR • PET/CT (CPT® 78815)
If both CT and MRI are inconclusive	• PET/CT (CPT® 78815)
If CT, MRI, and PET/CT are inconclusive	• PET/MRI (CPT® 78813 and 76498)

Evidence Discussion

If disease was completely resected and normal CA-125 or other markers normal, then no imaging is medically necessary. If there any question or signs or symptoms of recurrence, then the appropriate imaging is similar to that of initial staging. To monitor response to treatment, CT is medically necessary every two cycles.

NCCN stated that advanced imaging may improve assessment of metastases and assist in staging.[1] For individuals who have renal insufficiency and therefore are unable to undergo contrasted CT imaging of the abdomen and pelvis, the preferred substitute imaging is MRI with contrast. This imaging will provide the necessary level of soft tissue detail that would not be achievable with a non-contrasted CT. NCCN stated "MRI has been shown to provide equivalent accuracy for staging and comparable accuracy for predicting peritoneal tumor volume, and can be useful if CT results are inconclusive".[1] Thus, MRI is a tool presented for use in the event that CT results are inconclusive or conflict with the clinical picture. Chest imaging via CT either with or without contrast is necessary for suspected pulmonary disease or if there is concern for metastatic disease. NCCN stated this imaging is helpful to detect pleural or pulmonary metastases, as well as pleural effusion, which may help with treatment planning.[1] PET/CT is a helpful tool in evaluation of indeterminate lesions on other imaging as it is shown to have high accuracy for detection of metastases.[1]

Ovarian Cancer – Surveillance (ONC-21.5)

ON.OC.0021.5.A
v3.0.2026

- Germ cell tumors and sex cord stromal tumors (granulosa cell tumors), are imaged according to Testicular, Ovarian and Extragonadal Germ Cell Cancer (ONC-20).

Indication	Medically Necessary Imaging Study
Stages I-III	• Advanced imaging is not medically necessary for surveillance
Measurable metastatic disease on maintenance therapy or being monitored off therapy	Every 3 months for up to 5 years after completion of active treatment: • CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ MRI Abdomen and MRI Pelvis without and with contrast (CPT® 74183 and CPT® 72197) in lieu of CT for individuals with renal insufficiency. • CT with contrast of previously involved body areas • CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) for known history of chest involvement

Evidence Discussion

For stages I to III, there is no need for advanced imaging if there are no signs or symptoms. If on maintenance or if there is measurable disease present, CT of the areas involved is medically necessary every three months for up to 5 years. For individuals who have renal insufficiency and therefore are unable to undergo contrasted CT imaging of the abdomen and pelvis, the preferred substitute imaging is MRI with contrast. This imaging will provide the necessary level of soft tissue detail that would not be achievable with a non-contrasted CT.[1]

Uterine Cancer – General Considerations (ONC-22.0)

ON.UC.0022.0.A

v3.0.2026

- Gestational trophoblastic neoplasia (GTN) – see: **Molar Pregnancy and Gestational Trophoblastic Neoplasia (GTN) (PV-16.1)** in the Pelvic Imaging Guidelines.
- Most common cell type is adenocarcinoma. Uterine sarcomas are also imaged according to this guideline.
- Staging of uterine cancer is primarily surgical. Advanced imaging is not routinely medically necessary pre-operatively for laparoscopic/minimally invasive surgery unless initial staging criteria are met. Pelvic and para-aortic lymphadenectomy can still be performed.

Health Equity Considerations

Endometrial cancer develops in the endometrium in the lining of the uterus and is the most common gynecological malignancy in the United States. Risk factors include increasing age, hormone therapy, obesity, and family history/genetic predisposition.[9] According to the National Cancer Institute's Surveillance, Epidemiology, and End Results Program (SEER), in 2025, there were 69,120 estimated new cases and 13,860 estimated deaths due to endometrial cancer. In addition, SEER reports that non-Hispanic Black individuals have the highest rate of new cases of uterine cancer at 30.6 per 100,000 compared to 27.6 per 100,000 persons for non-Hispanic White individuals.[10] Factors that have impacted the rise in new uterine cancer cases overall include a decline in hysterectomy rates, lower use of estrogen plus progesterone hormonal therapy, and an increasing obesity rate.[11]

An annual increase in morality rates among non-Hispanic Black, Hispanic, and non-Hispanic Asian and Pacific Islander individuals was higher than in non-Hispanic White women (1.5%, 1.7%, 2.5%, and 1.0%, respectively) over the years 1999 to 2016. Non-Hispanic Black women experience uterine cancer mortality at a twofold greater rate than any other racial or ethnic group.[12] Rodriguez et al. noted non-Hispanic Black women had the lowest percentage of adherence to the National Comprehensive Cancer Network clinical guidelines.[13] Proposed factors leading to this increase in mortality rates among non-Hispanic Black women include structural racism and the inability to access and receive quality healthcare services, provider issues with bias and discrimination affecting clinical decision making, and individual issues like genetic differences, educational differences, and socioeconomic differences such as no or publicly funded insurance.[11] As the increasing rate of endometrial cancer continues, factors impacting

women, especially non-Hispanic Black women, need further investigation in the hopes of reducing disease incidence.

Uterine Cancer – Initial Work-Up/Staging (ONC-22.2)

ON.UC.0022.2.A
v3.0.2026

Indication	Medically Necessary Imaging Study
ANY of the following: • Extra-uterine disease suspected • To assess local extent of tumor prior to fertility-sparing surgery for well-differentiated Stage IA (grade 1) uterine cancer • Poor surgical candidate (due to medical comorbidities) considering medical therapy	• MRI Pelvis without and with contrast (CPT® 72197) • Transvaginal ultrasound (CPT® 76830) if MRI is contraindicated • Chest x-ray ◦ CT Chest with contrast (CPT® 71260) for: ▪ New or worsening pulmonary symptoms ▪ New or worsening chest x-ray findings In addition, for surgical staging: • Lymph system imaging (lymphoscintigraphy, CPT® 78195) ◦ SPECT/CT (CPT® 78830) if requested
ANY of the following: • Abdominal symptoms or abnormal examination findings • Elevated LFTs • Other imaging studies suggest liver involvement	ONE of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen with contrast (CPT® 74160)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
ANY of the following high-risk histologies: • Papillary serous • Clear cell • High-grade/poorly differentiated endometrioid carcinoma • Uterine sarcomas: ◦ Carcinosarcoma ◦ Soft tissue sarcoma of the uterus ◦ Leiomyosarcoma ◦ Rhabdomyosarcoma ◦ Undifferentiated sarcoma ◦ Endometrial stromal sarcoma	• CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast • Lymph system imaging (lymphoscintigraphy, CPT® 78195) ◦ SPECT/CT (CPT® 78830) if requested
Tumors detected incidentally or incompletely staged surgically ***and*** ANY of the following high-risk features: • Myoinvasion >50% • Cervical stromal involvement • Lymphovascular invasion • Tumor >2cm	• CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast
Inconclusive findings on conventional imaging	• PET/CT scan (CPT® 78815)

Evidence Discussion

- The National Comprehensive Cancer Network guidelines (NCCN) for non-fertility sparing treatment recommended considering chest imaging with chest x-ray.[1] If an abnormality is seen on chest x-ray, or if there are symptoms of chest involvement, then chest CT is medically necessary. Both NCCN and the American College of Radiology noted that MRI of the pelvis is the preferred imaging modality when pretreatment assessment of local tumor extent is indicated due to suspected extra-uterine disease or prior to fertility sparing treatment.[1,6]
- Transvaginal ultrasound can be done if MRI is contraindicated or unavailable.[1]
- If distant metastatic disease is suspected based on abnormal physical examination findings, or for high-grade endometrioid carcinoma, serous, clear cell or

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

carcinosarcoma, cross-sectional imaging with CT Chest and CT Abdomen and Pelvis is medically necessary.[1]

- For incidental findings of endometrial cancer after hysterectomy or incompletely surgically staged with uterine risk factors (myoinvasion of over 50%, cervical stromal involvement or tumor larger than 2cm), consideration should be given to CT Chest/ Abdomen and Pelvis to evaluate for distant metastatic disease per NCCN guidelines.[1]
- FDG-PET/CT is medically necessary in select individuals if metastases is suspected and other cross-sectional imaging is inconclusive.[1]
- Although endometrial cancer (EC) is surgically staged, preoperative imaging can help tailor surgery and medical treatment in cases as outlined by NCCN and ACR.[1,6] MRI or transvaginal ultrasound is valuable to assess local tumor extent. CT and/or PET-CT is valuable to assess lymph node metastases and distant spread. Preoperative imaging may identify deep myometrial invasion, cervical stromal involvement and metastatic disease. Although these imaging methods may provide information about likely tumor stage, the reported accuracies for preoperative staging of endometrial cancer by conventional imaging have not yet been good enough to replace surgical staging.[8]
- MRI Pelvis has long been established as a valuable imaging method in the preoperative staging of endometrial cancer because it allows the most accurate evaluation of the extent of the pelvis tumor. A meta-analysis showed that the efficacy of contrast-enhanced MRI is significantly better than that of non-contrast MRI and US, and tended toward better results than CT, in evaluating the depth of myometrial invasion in individuals with EC.[6]
- Transvaginal ultrasound may be used if MRI is contraindicated. A study found this imaging modality to have a 79.5% sensitivity and an 89.6% specificity for detecting deep myometrial invasion. However, MRI showed greater accuracy than ultrasound and ultrasound is limited in the setting of concomitant benign disease.[6]
- CT Chest, Abdomen and Pelvis may be used for detection of lymph node metastases, if distant metastatic disease is suspected as per NCCN and ACR listed above.[1,6]
- FDG-PET/CT is medically necessary if distant metastatic disease is suspected and CT scans are inconclusive. A meta-analysis reported that the overall pooled sensitivity, specificity, and accuracy of using FDG-PET/CT for detection of lymph node metastasis in EC was 72.0%, 94.0%, and 88.0%, respectively.[6]

Uterine Cancer – Restaging/Recurrence (ONC-22.3)

ON.UC.0022.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
• Unresected disease • Medically inoperable disease • Incomplete surgical staging • Difficult or abnormal examination • Elevated LFTs or rising tumor markers • Signs or symptoms of recurrence	• CT Chest (CPT® 71260) **and** • CT Abdomen and Pelvis with contrast (CPT® 74177)
Monitoring response to chemotherapy (every 2 cycles, ~every 6-8 weeks) for: • Unresected primary disease • Metastatic disease	• CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Chest with contrast (CPT® 71260) for: ◦ Known prior thoracic disease ◦ New or worsening pulmonary symptoms ◦ New or worsening chest x-ray findings
Any of the following: • After fertility sparing treatment • Inconclusive CT scan findings	• MRI Pelvis without and with contrast (CPT® 72197)
• Inconclusive findings on conventional imaging	• PET/CT (CPT® 78815)

Evidence Discussion

- Recurrence rates for low- or intermediate-risk individuals with endometrial cancer are infrequent. A recent review of post-treatment surveillance and diagnosis of recurrence in people assigned female at birth, or individuals with gynecologic cancers sponsored by the Society of Gynecologic Oncology recommends that radiologic evaluation be used only to investigate suspicion of recurrent disease because of symptoms or physical exam and not for routine surveillance after treatment.[5]
- CT Chest, Abdomen, and Pelvis is useful for suspected recurrence of disease based on abnormal physical examination findings and/or new pelvis, abdominal or pulmonary symptoms.[1] A study reported that 45 asymptomatic individuals had

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

routine CT scans, and recurrence was diagnosed by CT in only 2 (4.4%), whereas 37 symptomatic individuals had CT scans for suspicion of recurrence, and it was confirmed by CT in 17 (46%).[6]

- MRI of the pelvis may be done after fertility sparing treatment for persistent endometrial carcinoma.[1] In individuals with persistent endometrial carcinoma after 6 months of failed hormonal therapy, pelvic MRI to exclude myoinvasion and nodal/ovarian metastasis is recommended before continuing fertility-sparing therapy.[1]
- FDG-PET/CT may give further clinically applicable information in cases where conventional imaging is inconclusive. As per the prior meta-analysis, the overall pooled sensitivity, specificity, and accuracy of using FDG-PET/CT for detection of lymph node metastasis in EC was 72.0%, 94.0%, and 88.0%, respectively.[6]

Uterine Cancer – Surveillance (ONC-22.4)

ON.UC.0022.4.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Stage I-III of uterine carcinoma	Advanced imaging is not routinely medically necessary
Measurable metastatic disease on maintenance therapy or being monitored off therapy	Every 3 months for up to 5 years after completion of definitive treatment: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved body areas
All stages of uterine sarcoma: • Soft tissue sarcoma of the uterus • Leiomyosarcoma • Adenosarcoma • Carcinosarcoma • Rhabdomyosarcoma • Undifferentiated sarcoma • Endometrial stromal sarcoma	CT Chest (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) every 3 months for 3 years, then every 6 months for 2 years, and then every 1-2 years until year 10

Evidence Discussion

- Advanced imaging is not medically necessary for surveillance for non-metastatic, asymptomatic disease in endometrial cancer. A review of post-treatment surveillance and diagnosis of recurrence in individuals with gynecologic cancers sponsored by the Society of Gynecologic Oncology recommended that radiologic evaluation be used only to investigate suspicion of recurrent disease because of symptoms or physical exam and not for routine surveillance after treatment.[5]
- Measurable metastatic disease can be followed with CT Abdomen and Pelvis and CT of previously involved body areas every 3 months for 5 years after treatment.
- For all stages of uterine sarcoma, CT Chest, Abdomen and Pelvis is medically necessary every 3 months for 3 years, every 6 months for 2 years, and then every 1-2 years until year 10.[1]

Gestational Trophoblastic Neoplasia (GTN) (ONC-22.5)

ON.UC.0022.5.A

v3.0.2026

- The most common form of gestational trophoblastic disease (GTD) is hydatidiform mole (HM), a benign form, also known as molar pregnancy.
  - See: **Molar Pregnancy and GTN (PV-16.1)**
- Gestational trophoblastic neoplastic disorders including a malignant form of GTD, and can present as invasive mole, choriocarcinoma, placental site trophoblastic tumor (PSTT), or epithelioid trophoblastic tumor (ETT). GTN cells are malignant and can metastasize to other organs such as lungs, brain, bone and vagina. These tumors have a high likelihood of cure and treatment with methotrexate usually allows for fertility preservation.
- Surveillance is generally with serial monitoring of hCG levels, and advanced imaging is reserved for high-risk histologies where hCG levels may not be a reliable marker.

Indication	Medically Necessary Imaging Study
Initial staging	• CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177)
EITHER of the following: • Pulmonary metastases noted on CT scan • Signs/symptoms of CNS involvement	• MRI Brain without and with contrast (CPT® 70553)
EITHER of the following: • Monitoring response to systemic therapy (every 2 cycles, i.e., 6-8 weeks) • Suspected progression	• CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Surveillance for any of the following high risk histologies: • Placental site trophoblastic tumor (PSTT) • Epithelioid trophoblastic tumor (ETT)	Annually for 2 years: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177)

Evidence Discussion

- The most common form of GTD is hydatidiform mole (HM), also known as molar pregnancy. HMs are considered a benign, premalignant disease.[7]
- Initial determination of suspected HM is often made based on ultrasound findings in combination with clinical symptoms and hCG levels.[7]
- Gestational trophoblastic neoplastic disorders include a malignant form of GTD, and can present as invasive mole, choriocarcinoma, placental site trophoblastic tumor (PSTT), or epithelioid trophoblastic tumor (ETT). GTN cells are malignant and can metastasize to other organs such as lungs, brain, bone, and vagina.
- Initial staging of GTN includes a CT of chest and CT of abdomen and pelvis.
- If pulmonary metastases are noted on CT Chest or for signs or symptoms of central nervous system (CNS) involvement, MRI Brain is medically necessary to evaluate for metastatic disease. Rates of CNS metastases are low with post-molar GTN, but approximately 20% of individuals with choriocarcinoma have CNS involvement.[7]
- For monitoring response to treatment or for suspected progression CT Chest, Abdomen and Pelvis is performed.
- Post-treatment surveillance in general is done with monitoring of hCG levels in individuals with post-molar GTN or choriocarcinoma, where hCG is a reliable tumor marker.[7]
- Surveillance imaging for placental site or epithelioid trophoblastic tumor can be done with CT Chest, Abdomen, and Pelvis annually for 2 years. Post-treatment imaging is medically necessary for follow-up after treatment of PSTT and ETT, where hCG is a less reliable tumor marker.[7]

Cervical Cancer – General Considerations (ONC-23.0)

ON.CV.0023.0.A

v3.0.2026

- Primary histology for cervical cancer is squamous cell. Other, less common histologies are adenosquamous and adenocarcinoma. If biopsy is consistent with one of these less common histologies, it is necessary to clarify that tumor is not of primary uterine origin.
- If the primary histology is uterine in origin, follow imaging recommendations for uterine cancer, see: **Uterine Cancer (ONC-22)**.

Health Equity Considerations

Cervical cancer screening and treatment improvements have led to the decrease in disease incidence by more than one-half since the mid-1970s. According to the National Cancer Institute, new cervical cancer cases are estimated to be 13,360 in 2025, and the estimated number of deaths is 4,320.[8] The United States Preventive Services Task Force (USPSTF) recommends screening for cervical cancer every 3 years with cervical cytology alone in women aged 21 to 29 years. For women aged 30 to 65 years, the USPSTF recommends screening every 3 years with cervical cytology alone, every 5 years with high-risk human papillomavirus (hrHPV) testing alone, or every 5 years with hrHPV testing in combination with cytology (cotesting).[9]

Treatment for cervical cancer at the early stage is effective with early detection and well-timed follow-up. Black women have the highest overall mortality rates and lowest 5-year relative survival, irrespective of subtype and stage.[10] Some of the basis of this data can be linked to the lack of timely and appropriate treatment after receiving abnormal screening.[11] Barriers to the compliance of Black women to screening or treatment are multi-factorial, including financial problems, comorbidities, beliefs, and transportation.[11,12] Insurance coverage is an important factor in accessing cervical cancer screening. According to the USPSTF Cervical Cancer Recommendation Statement (2018), "23.1% of women without health insurance and 25.5% of women with no regular health care clinician reported not receiving a Pap test in the past 5 years, compared with 11.4% of the general population. Insurance status may interact with other demographic factors, such as race/ethnicity and age, to increase disparities."[9] Efforts are needed to address the factors that hamper screening or treatment to improve overall mortality rates and 5-year relative survival in Black women.

Cervical Cancer – Initial Work-Up/ Staging (ONC-23.2)

ON.CV.0023.2.A
v3.0.2026

Indication	Medically Necessary Imaging Study
All individuals with one of the following: • Stage I-IVA • Stage IVB amenable to local treatment	• MRI Pelvis without and with contrast (CPT® 72197)
Stage IB1-IB3, non-fertility sparing treatment	In addition to MRI Pelvis above, any ONE of the following combinations: • PET/CT (CPT® 78815) or • CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) or • PET/MRI (CPT® 78813 and CPT® 76498)
ANY of the following: • Stage 1B1-IB3, fertility-sparing treatment • Stage II-IVA • Any size cervical cancer incidentally found in a hysterectomy specimen	In addition to MRI Pelvis above, any ONE of the following combinations: • PET/CT (CPT® 78815) or • CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) or • CT Chest without contrast (CPT® 71250) and CT Abdomen and Pelvis with contrast (CPT® 74177)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Small cell neuroendocrine carcinoma of the cervix (NECC)	MRI Brain without and with contrast (CPT® 70553) and any ONE of the following combinations: • PET/CT (CPT® 78815) or • CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) or • CT Chest without contrast (CPT® 71250) and CT Abdomen and Pelvis with contrast (CPT® 74177)
Inconclusive findings on conventional imaging	• PET/CT (CPT® 78815)

Evidence Discussion

- MRI Pelvis is recommended by NCCN in virtually all individuals, with exception of stage IVB not amenable to local treatment. MRI Pelvis imaging is used to assess local disease extent, to help with surgical treatment planning, and to help with any radiation treatment planning.[1]
- Systemic imaging is medically necessary to assess for lymphadenopathy and distant metastases. The goal of systemic imaging is to evaluate for metastatic disease. CT imaging of the chest, abdomen, and pelvis are useful; PET/CT is the recommended study of choice in higher stages of disease. NCCN stated of non-fertility-sparing approaches, "depending on their stage and disease bulk, individuals with stage IB or IIA tumors can be treated with surgery, RT, or concurrent chemoradiation. A combined PET/CT scan can be performed to rule out extra pelvic disease before deciding how to treat these individuals. Neck/chest/abdomen/pelvis/groin FDG-PET/CT is preferred to evaluate metastatic disease. A chest/abdomen/pelvis CT or FDG-PET/MRI can also be performed."[1]
- Meta-analyses have shown CT with intravenous (IV) contrast to have 43%-55% sensitivity and 71% specificity for parametrial invasion, and 41% sensitivity and 92% specificity for bladder invasion In comparison, MRI demonstrated 71% specificity (95% confidence interval [CI], 62%-79%) and 91% sensitivity (95% CI, 88%-93%) for parametrial invasion, and 84% sensitivity (95% CI, 57%-95%) and 95% specificity (95% CI, 87%-98%) for bladder invasion.
- Small cell neuroendocrine carcinoma of the cervix (NECC) is considered an aggressive form of cervical cancer. The NCCN-recommended studies are adapted

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

from their own guidelines on neuroendocrine tumors and non-small cell lung cancers.[1] Brain imaging is medically necessary in this cell type to evaluate for metastatic disease to the brain.

- PET/CT remains a useful tool for evaluation of inconclusive findings on conventional imaging.

Cervical Cancer – Restaging/Recurrence (ONC-23.3)

ON.CV.0023.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Stage I treated with definitive surgery	• See: **Cervical Cancer – Surveillance (ONC-23.4)**
EITHER of the following: • Stage IB3 • Stage I treated with post-operative adjuvant radiation or chemoradiation due to positive nodes, positive parametria, positive margins, or local cervical factors	• PET/CT (CPT® 78815) 3-6 months post-completion of therapy
Stage II-IV	ONE of the following within 3-6 months of completion of therapy: • PET/CT (CPT® 78815) or • CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast)
Small cell NECC, treated with primary chemoradiation	ONE of the following after completion of therapy: • PET/CT (CPT® 78815) and MRI Brain without and with contrast (CPT® 70553) or • CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast and MRI Brain without and with contrast (CPT® 70553)
Inconclusive findings on CT scan or PET/CT	MRI Pelvis without and with contrast (CPT® 72197)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Unresectable disease or metastatic disease on systemic treatment	Every 2 cycles of treatment (commonly every 6 to 8 weeks): • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of other involved or symptomatic areas
Inconclusive conventional imaging	• PET/CT (CPT® 78815)
Suspected or biopsy proven recurrence	EITHER of the following, not both: • PET/CT (CPT® 78815) OR • CT Chest (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177)

Evidence Discussion

- The main purpose of imaging after primary surgery is to determine whether distant metastases are present.[1] Thus, repeating systemic imaging for certain individuals in whom surgery was not definitive treatment is recommended.
- For unresectable or metastatic disease on systemic treatment, CT Chest/Abdomen/Pelvis every 2 cycles is medically necessary.
- PET/CT remains a useful tool for evaluation of inconclusive conventional imaging. MRI Pelvis, given its excellent resolution of soft-tissue imaging, is a recommended tool for evaluation of an inconclusive CT or PET/CT.[1]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Cervical Cancer – Surveillance (ONC-23.4)

ON.CV.0023.4.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Stage I disease treated with fertility sparing approach	• MRI Pelvis without and with contrast (CPT® 72197) at 6 months after surgery and then annually for 2-3 years
Small cell NECC	Once, 3-6 months after completion of therapy: • PET/CT (CPT® 78815) Then, every 3 months for 1 year, then every 6 months: • CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast and MRI Brain without and with contrast (CPT® 70553)
All other individuals	• No routine advanced imaging is medically necessary in asymptomatic individuals.

Evidence Discussion

With stage I post fertility-sparing treatment, MRI Pelvis is supported by NCCN for surveillance imaging at 6 months post-operatively and then annually for 2-3 years. For small-cell NECC, NCCN supported PET/CT at completion of therapy and supported ongoing surveillance, but a timeframe is not provided. There are little data in the medical literature specific to this topic. It is therefore reasonable to follow the NCCN-recommended surveillance schedule for extrathoracic small-cell neuroendocrine tumors for small-cell NECC.

Anal Carcinoma – General Considerations (ONC-24.0)

ON.AN.0024.0.A

v3.0.2026

- Most are squamous cell carcinomas, although some transitional and cloacogenic carcinomas are seen.
- Adenocarcinoma of the anal canal is managed as rectal cancer according to **Colorectal and Small Bowel Cancer (ONC-16)**.
- Squamous cell carcinoma of the perianal region (up to 5cm radius from the anal verge) are imaged according to anal carcinoma guidelines.
- Bowen's disease and Paget's disease of the perianal and perigenital skin are considered non-invasive/in-situ conditions and do not routinely require advanced imaging. See: **Non-Melanoma Skin Cancers – Initial Work-up/Staging (ONC-5.6)**.

Anal Carcinoma – Suspected/Diagnosis (ONC-24.1)

ON.AN.0024.1.A
v3.0.2026

Indication	Medically Necessary Imaging Study
All	• No advanced imaging prior to biopsy

Evidence Discussion

Advanced imaging prior to biopsy is not medically necessary as most tumors are staged clinically by direct examination and microscopic confirmation (biopsy).[1]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Anal Carcinoma – Initial Work-up/ Staging (ONC-24.2)

ON.AN.0024.2.A
v3.0.2026

Indication	Medically Necessary Imaging Study
All individuals	• CT Chest with contrast (CPT® 71260) and Any ONE of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Abdomen with contrast (CPT® 74160) and MRI Pelvis without and with contrast (CPT® 72197)
• Stage II-III Squamous Cell Carcinoma of the Anal Canal and no evidence of metastatic disease by conventional imaging • Inconclusive findings on conventional imaging	• PET/CT (CPT® 78815)

Evidence Discussion

All individuals undergo CT Chest with contrast and either CT Abdomen and Pelvis with contrast or CT Abdomen with contrast and MRI Pelvis without/with contrast. CT allows information on whether there is other organ involvement or possible disease spread. PET/CT is medically necessary in stage II-III disease with no evidence of distant metastatic disease by conventional imaging or if conventional imaging is inconclusive. PET/CT is useful in assessing pelvic nodes and has been shown to change the nodal status/TNM stage in up to 41% of individuals. PET/CT does not replace a diagnostic CT in initial staging.[1,11]

Click Here to Return to the Main TOC

Anal Carcinoma – Restaging/Recurrence (ONC-24.3)

ON.AN.0024.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Stage I treated with complete surgical resection	• See: **Anal Carcinoma – Surveillance (ONC-24.4)** for surveillance guidelines
Stages I, II and III – post chemoradiation evaluation	• CT Chest with contrast (CPT® 71260) or without contrast (CPT® 71250) AND any ONE of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast
Metastatic (stage IV) disease	• CT Abdomen and Pelvis with contrast (CPT® 74177) every 2 cycles (generally 6 to 8 weeks) on treatment • CT Chest with contrast (CPT® 71260) if chest x-ray is abnormal or if symptoms of chest involvement
• Difficult or abnormal examination • Elevated LFTs • Signs or symptoms of recurrence • Biopsy proven recurrence	Preferably using same imaging studies as used in initial imaging: • CT Chest (CPT® 71260) with contrast and Any ONE of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast
Inconclusive findings on conventional imaging	• PET/CT (CPT® 78815)

Evidence Discussion

Due to low risk of recurrence, stage I treated with complete surgical resection would follow surveillance guidelines that do not recommend any routine imaging. For stages I, II, and III treated with chemoradiation, CT Abdomen and Pelvis, or MRI Abdomen and Pelvis should be obtained upon completion of therapy. Stage IV disease on treatment

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

should undergo CT Abdomen and Pelvis every 2 cycles with imaging of the chest if chest x-ray is abnormal or symptoms develop. If recurrence is suspected, CT Chest with either CT Abdomen and Pelvis or MRI Abdomen and Pelvis should be performed. NCCN stated that imaging for recurrence is preferred to mirror the same imaging studies as used in initial imaging. PET/CT is medically necessary for inconclusive findings on conventional imaging.[1]

Anal Carcinoma – Surveillance (ONC-24.4)

ON.AN.0024.4.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Stage I	• Advanced imaging is not routinely medically necessary for surveillance
• Stage II • Stage III • Local recurrence treated definitively	• CT Chest (CPT® 71260) with contrast or CT Chest without contrast (CPT® 71250) annually for 3 years • And ANY one of the following annually for three years: ◦ CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)
Stage IV – measurable metastatic disease on maintenance treatment or being observed off treatment	Every 3 months for up to 5 years after completion of all treatment: • CT Chest (CPT® 71260) with contrast • CT Abdomen and Pelvis with contrast (CPT® 74177)

Evidence Discussion

For individuals with Stage II-III disease or had definitive treatment of a local recurrence, CT Chest with or without contrast plus either CT Abdomen and Pelvis with contrast or MRI Abdomen and Pelvis without/with contrast is medically necessary annually for 3 years. NCCN stated that FDG PET/CT is not indicated for surveillance of local recurrence treated definitively.[1]

Cancers of External Genitalia – Initial Work-Up/Staging (ONC-24.6)

ON.AN.0024.6.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Clinical node negative **vulvar** cancer with ANY of the following: • Lesion >2cm • Any size with stromal invasion >1mm	• For planned sentinel lymph node evaluation: Lymph system imaging (lymphoscintigraphy, CPT® 78195) ◦ SPECT/CT (CPT® 78830) if requested
For stage II or higher **vulvar** cancer or suspected metastatic vulvar cancer based on one of the following: • Abnormal physical exam findings • Bulky vulvar tumor (≥4cm or close to critical structures) • Vaginal, urethral, or anal involvement • Delay in presentation or treatment • Pelvic, abdominal, or pulmonary symptoms	ONE of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) OR • CT Abdomen with contrast (CPT® 74160) and MRI Pelvis without and with contrast (CPT® 72197) • CT Chest with contrast (CPT® 71260) is medically necessary only for: ◦ Signs/symptoms suggestive of chest involvement ◦ Abnormal findings on chest x-ray

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Vaginal carcinoma	ONE of the following combinations: • PET/CT (CPT® 78815) and MRI Pelvis without and with contrast (CPT® 72197) or • CT Abdomen and Pelvis with contrast (CPT® 74177) and CT Chest with contrast (CPT® 71260) or • CT Abdomen with contrast (CPT® 74160) and MRI Pelvis without and with contrast (CPT® 72197) and CT Chest with contrast (71260)
Penile carcinoma with ANY of the following: • Non-palpable inguinal lymph nodes and intermediate or high-risk lesion (T1b or any T2 or greater) • Palpable inguinal lymph nodes • Difficult pelvic node assessment on physical exam	Any ONE of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast • CT Abdomen with contrast (CPT® 74160) and MRI Pelvis without and with contrast (CPT® 72197) • CT Chest with contrast (CPT® 71260)
• Inconclusive findings on conventional imaging • Pelvic nodes enlarged but biopsy not technically feasible	• PET/CT (CPT® 78815)

Evidence Discussion

Lymphoscintigraphy is appropriate for the workup of vulvar cancer since the disease spreads through skin layer and into the lymph system. FIGO surgical staging is used after superficial removal of the lesion. If it is a large (>2cm) or stromal invasion (>1mm), then spread is evaluated with CT. CT imaging plays an important role in stage II or higher disease by helping to delineate the extent of tumor and assisting in treatment planning.[3] CT of the chest is valuable if there are signs or symptoms of chest involvement. In the evaluation of vaginal carcinoma, NCCN stated that PET/CT is the preferred imaging for evaluation of metastatic disease (conventional CT of the

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

chest, abdomen, and pelvis remains a recommended option). MRI Pelvis is medically necessary in addition to PET/CT or conventional CT for assessment of local disease extent.[14] For the initial workup of penile cancer, cross-sectional imaging with CT or MRI of the abdomen and pelvis are necessary for pelvic node evaluation in circumstances where there is greater chance of lymph node involvement, palpable lymph nodes, or when it is difficult to physically assess potential lymph node involvement.[2] Evaluation of inguinal lymph nodes "has been identified as the single most important prognostic indicator in determining long-term survival in individuals with invasive penile squamous cell carcinoma".[2] MRI can also provide information on depth of tumor invasion.[2] PET/CT remains a problem-solving tool for inconclusive conventional imaging. PET/CT has higher sensitivity for individuals with node-positive penile cancer than those without, thus it is used as a tool of lymph node assessment when biopsy is not technically feasible.[2]

Cancers of External Genitalia – Restaging/Recurrence (ONC-24.7)

ON.AN.0024.7.A
v3.0.2026

Indication	Medically Necessary Imaging Study
• Difficult or abnormal examination • Elevated LFTs • Signs or symptoms of recurrence • Biopsy proven recurrence	• CT Chest with contrast (CPT® 71260) And ANY one of the following: • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast
EITHER of the following: • individuals receiving systemic treatment for measurable disease • At the end of definitive therapy	Any ONE of the following, every 2 cycles (generally 6 to 8 weeks) during treatment at the end of planned chemotherapy treatment: • CT Abdomen and Pelvis with contrast (CPT® 74177) or • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast or • CT Abdomen with contrast (CPT® 74160) and MRI Pelvis (CPT® 72197) AND • CT Chest with contrast (CPT® 71260)
Vaginal primary tumor treated with upfront radiation therapy	• PET/CT (CPT® 78815) at least 12 weeks after completion of radiation therapy ◦ MRI Pelvis without and with contrast (CPT® 72197) is medically necessary if PET/CT not available (can be performed sooner than 12 weeks after completion of therapy) ◦ MRI Pelvis without and with contrast (CPT® 72197) is medically necessary for clarification of PET/CT findings
Vulvar carcinoma following definitive primary therapy with chemoradiation or surgery	3-6 months after primary therapy: • MRI Pelvis without and with contrast (CPT® 72197)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Inconclusive findings on conventional imaging	• PET/CT (CPT® 78815)

Evidence Discussion

Signs or symptoms of recurrence should be imaged with CT or MRI to evaluate for metastatic disease. Specifically for vaginal cancer, PET/CT is preferred to re-image three to four months after the completion of radiation therapy to determine response to treatment while avoiding false-positive from recent radiation. If PET/CT is inconclusive, NCCN stated that MRI is the preferred imaging for clarification.[14] For vulvar cancer, reassessment with MR imaging is necessary to assess response to treatment and re-evaluate lymph node involvement.[3] PET/CT can be used as a tool for evaluation of inconclusive conventional imaging.

Click Here to Return to the Main TOC

Cancers of External Genitalia – Surveillance (ONC-24.8)

ON.AN.0024.8.A
v3.0.2026

Indication	Medically Necessary Imaging Study
• All stages of vulvar and vaginal cancers	• See: **ONC-24.7** for post-treatment imaging 3-6 months after completion of therapy. No additional routine advanced imaging for asymptomatic surveillance.
• Penile Cancer: stage I-IIIA	• CT Abdomen and Pelvis with contrast (CPT® 74177) every 6 months for 2 years, and then every 12 months for 2 years
• Penile cancer: stages IIIB-IV	• CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) every 3 months for one year, then every 6 months for 3 more years

Evidence Discussion

If no symptoms or findings on recent physical examination, then advanced imaging is not medically necessary for all stages of vulvar and vaginal cancer.[3,14] For stage I-IIIA penile cancer, the NCCN supported CT Abdomen and Pelvis for surveillance, with chest imaging via radiograph only on the same schedule as CTs. For stages IIIB-IV penile cancer, chest CT is medically necessary for surveillance with more frequent CT Abdomen and Pelvis than in early stage disease.[2]

Multiple Myeloma and Plasmacytomas – General Considerations (ONC-25.0)

ON.MM.0025.0.A

v3.0.2026

- Multiple myeloma (MM) is a neoplastic disorder characterized by the proliferation of a single clone of plasma cells derived from B cells which grows in the bone marrow and adjacent bone, producing skeletal destruction.
- Multiple myeloma group of disorders can be classified as below, which influence imaging modality of choice.

Condition	Monoclonal protein	Bone marrow plasma cells	CRAB criteria**
Solitary Plasmacytoma (biopsy proven tumor containing plasma cells)	<3gm/dL	Absent	Absent
Monoclonal Gammopathy of Unknown Significance (MGUS)	<3gm/dL	<10%	Absent
Smoldering Myeloma (SMM) (stage I MM or asymptomatic MM)	≥3gm/dL	10% - 60%	Absent
Multiple Myeloma (MM)	≥3gm/dL	≥10%	Present

**CRAB criteria = hypercalcemia, renal insufficiency, anemia, lytic bony lesions

- Diagnosis and monitoring of response to therapy is primarily with laboratory studies that include urine and serum monoclonal protein levels, serum-free light chain levels, LDH and beta-2 microglobulin. Routine advanced imaging to monitor response to treatment is not medically necessary.
- Rarely, (<5%), an individual may have nonsecretory myeloma, which does not produce measurable M-protein. These individuals require imaging as primary method to monitor disease.
- Other conditions that may present with monoclonal gammopathy include:
  - POEMS syndrome: Polyneuropathy, Organomegaly, Endocrinopathy, Monoclonal protein and Skin Changes – may also have sclerotic bone lesions and Castleman's disease. See: **Multiple Myeloma and Plasmacytomas – Initial Work-up/Staging (ONC-25.2)** for imaging recommendations.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Waldenström's Macroglobulinemia: IgM monoclonal protein along with bone marrow infiltration of small lymphocytes. See: **Waldenström Macroglobulinemia or Lymphoplasmacytic Lymphoma (ONC-27.10)** for imaging recommendations.
- Systemic Light chain Amyloidosis: light chain monoclonal protein in serum or urine with clonal plasma cells in bone marrow, systemic involvement of the kidneys, liver, heart, gastrointestinal tract or peripheral nerves due to amyloid deposition. See: **Multiple Myeloma and Plasmacytomas – Initial Work-up/Staging (ONC-25.2)** and **Cardiac Amyloidosis (CD-3.8)**for imaging recommendations for systemic light chain amyloidosis.

Multiple Myeloma and Plasmacytomas – Initial Work-Up/Staging (ONC-25.2)

ON.MM.0025.2.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Either of the following: • Confirmed myeloma • Myeloma suspected based on any of the following: ◦ Abnormal skeletal survey or other imaging ◦ Abnormal myeloma labs ◦ Signs/symptoms of multiple myeloma	EITHER of the following: • Whole-body low-dose skeletal CT (CPT® 76497) or • Whole-body FDG PET/CT (CPT® 78816)
Inconclusive findings on whole-body low-dose skeletal CT	• PET/CT (CPT® 78815 or CPT® 78816)
To discern smoldering myeloma from active myeloma and whole-body CT or PET are negative or inconclusive	ONE of the following: • MRI Bone Marrow Blood Supply (CPT® 77084) • Whole-body MRI (CPT® 76498) • CT contrast as requested of a specific area to determine radiotherapy or surgical candidacy, or for suspected extra-osseous plasmacytoma
Initial work-up of suspected or known POEMS syndrome	• CT Chest with contrast (CPT® 71260) and • CT Abdomen and Pelvis with contrast (CPT® 74177) • Whole-body FDG PET/CT (CPT® 78816) for sclerotic bone lesions on other imaging

v3.0.2026

Indication	Medically Necessary Imaging Study
Extra-osseous plasmacytoma response to initial therapy	Repeat imaging with ONE of the following, whichever modality was used at initial diagnosis: • Whole-body low-dose skeletal CT scan (CPT® 76497) • Whole-body FDG PET/CT (CPT® 78816) • Whole-body MRI (CPT® 76498) • CT of any previously involved area, contrast as requested • MRI of any previously involved area, contrast as requested
Known spine involvement with new neurological signs/symptoms or worsening pain	• MRI Cervical (CPT® 72156), Thoracic (CPT® 72157), Lumbar spine (CPT® 72158) without and with contrast
Treatment response assessment • After completion of primary therapy • Non-secretory multiple myeloma • To determine therapy response with inconclusive labs	Repeat imaging with ONE of the modalities below, whichever was used at initial diagnosis: • Whole-body low-dose skeletal CT scan (CPT® 76497) • Whole-body FDG PET/CT (CPT® 78816)
CAR-T cell therapy	Once before treatment and once 30-60 days after completion of treatment: • PET/CT (CPT® 78815 or CPT® 78816)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
ANY of the following: • Suspected progression or relapse/recurrence • Suspected progression of MGUS or SMM to a more malignant form	ONE of the following (using same modality as used at diagnosis): • Whole-body low-dose skeletal CT (CPT® 76497) • Whole-body FDG PET/CT (CPT® 78816) • Whole-body MRI (CPT® 76498)
ANY of the following: • Negative PET will allow change in management from active treatment to maintenance or surveillance. • Inconclusive findings on conventional imaging • Whole-body low-dose skeletal CT (CPT® 76497) is unfeasible and recurrence or progression is suspected	• PET/CT (CPT® 78815 or CPT® 78816)
To discern smoldering myeloma from active myeloma and whole-body CT or PET are negative or inconclusive	ONE of the following: • MRI Bone Marrow Blood Supply (CPT® 77084) • Whole-body MRI (CPT® 76498) • MRI without contrast, or MRI without and with contrast for any previously involved bony area or symptomatic area (including whole spine for spinal symptoms)
Stem cell transplant recipients	ONE of the following, once before transplant and once within 30-100 days after transplant: Imaging should use same modality as initial diagnosis. • Whole-body low-dose skeletal CT scan (CPT® 76497) • MRI Bone Marrow Blood Supply (CPT® 77084) • Whole-body MRI (CPT® 76498) • PET/CT (CPT® 78815 or CPT® 78816)

Multiple Myeloma and Plasmacytomas – Surveillance (ONC-25.4)

ON.MM.0025.4.A
v3.0.2026

Indication	Medically Necessary Imaging Study
• Smoldering myeloma • Multiple myeloma	ANY ONE of the following (using same imaging modality used at diagnosis) annually: • Whole-body low-dose skeletal CT (CPT® 76497) • MRI Bone Marrow Blood Supply (CPT® 77084) • Whole-body MRI (CPT® 76498) • Whole-body FDG PET/CT (CPT® 78816)
Solitary plasmacytomas	Any ONE of the following (using same imaging modality used at diagnosis) annually for 5 years: • Whole-body low-dose skeletal CT (CPT® 76497) • MRI Bone Marrow Blood Supply (CPT® 77084) • Whole-body MRI (CPT® 76498) • Whole-body FDG PET/CT (CPT® 78816)

Evidence Discussion

- Bone disease is the most frequent feature of multiple myeloma (MM), occurring in approximately two-thirds of individuals at diagnosis and in nearly all individuals during their disease.[13] Imaging is a key part of the evaluation of all individuals with suspected MM and plays a very important role in the management of MM.[26] It is necessary for detection of lytic bone lesions, which represent a marker of disease-related end-organ damage and are traditionally used to diagnose MM and to establish the need for immediate therapy.[3]
- The detection of bone and bone marrow lesions is crucial in the investigation of multiple myeloma and often dictates the decision to start treatment. Cross-sectional imaging (i.e., CT, PET/CT, MRI) is preferred because these modalities are more sensitive than plain radiographs for the detection of most skeletal lesions in MM.
- Whole-body low-dose CT (WBLDCT) can be used as a baseline assessment of bone involvement. CT is quick, convenient, relatively sensitive, and cost-effective in this scenario. WBLDCT was introduced to detect osteolytic lesions in the whole skeleton, with high accuracy, no need for contrast agents, and twofold to threefold lower radiation dose exposure compared with standard CT.[17,18] Low-dose whole-

body CT has increased sensitivity compared with conventional skeletal survey in the detection of bone disease, which can reveal information leading to changes in therapy and disease management that could prevent or delay the onset of clinically significant morbidity and mortality as a result of skeletal-related events.[16]

- 18F-FDG PET/CT imaging could identify sites of extra-medullary disease (EMD), which represent an unfavorable prognostic feature, and it helps to accurately differentiate between solitary plasmacytoma (SP) and MM, as well as to predict the risk of early progression from smoldering MM (SMM) to active disease. This is more sensitive than CT for the detection of extra medullary disease. The combination of functional imaging with positron emission tomography (PET) plus morphological assessment with CT makes this technique the most effective in identifying potential sites of EMD.[19] The use of FGD PET/CT can also confirm a suspected diagnosis of solitary plasmacytoma and can distinguish between smoldering and active multiple myeloma. Thus, NCCN stated that FDG PET/CT is the preferred imaging for initial diagnostic workup.[1]
- Whole-body MRI can distinguish between smoldering and active multiple myeloma, acting as a problem-solving tool when PET/CT or whole-body CT is inconclusive.[1]
- MRI is the elective imaging technique to assess the degree of BM PC infiltration, even before bone destruction is present, owing to its ability to visualize large volumes of BM.[7] MRI is highly sensitive for the detection of bone and bone marrow focal lesions and predictive of progression. Unlike CT and PET/CT, MRI can detect focal bone lesions that are not yet lytic (i.e., without advanced cortical bone destruction). Up to half of individuals without other evidence of end-organ damage with normal plain films may demonstrate tumor-related lesions on MRI.[21,22]
- Whole-body diffusion weighted MRI (DW-MRI), also known as MRI Bone Marrow Blood Supply, is a non-contrast study that covers from the vertex to the heels. Diffusion-weighted magnetic resonance imaging (DWI or DW-MRI) is the use of specific MRI sequences as well as software that generates images from the resulting data that uses the diffusion of water molecules to generate contrast in MR images. This produces images where the contrast between tissues is based on differences in the motion of water at a cellular level. As cellularity in marrow increases secondary either to disease or increased hematopoietic tissue, the amount of free water increases. The capability of WB DW-MRI to demonstrate both focal and diffuse marrow infiltration throughout the whole skeleton makes this extremely useful as a subjective tool for monitoring disease status and assessment of response.[23]

Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Chronic Myeloid Leukemias, Myelodysplastic Syndrome and Myeloproliferative Disorders (ONC-26.3)

ON.LM.0026.3.A

v3.0.2026

- Routine advanced imaging is not medically necessary in the evaluation and management of chronic myeloid leukemias, myelodysplastic syndromes or myeloproliferative disorders in the absence of specific localizing clinical symptoms or clearance for hematopoietic stem cell transplantation.
- See: **Hematopoietic Stem Cell Transplantation (ONC-29)** for imaging guidelines related to transplant.
- For work-up of elevated blood counts, see: **Paraneoplastic Syndromes – General Considerations (ONC-30.3)**.

Evidence Discussion

It is not routinely medically necessary to utilize advanced imaging for chronic myeloid leukemia, myelodysplastic syndromes, and myeloproliferative disorders. In the interest of safety such that infectious and iatrogenic complications are assessed in a timely manner, these guidelines provide flexibility for approval of advanced imaging for specific localizing symptoms, and a separate guideline section for imaging related to stem cell transplantation.[6,12,13]

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Chronic Lymphocytic Leukemia (CLL)/ Small Lymphocytic Lymphoma (SLL) (ONC-26.4)

ON.LM.0026.4.A

v3.0.2026

- PET imaging is not medically necessary in the evaluation of CLL/SLL with the exception of suspected Richter's transformation (see suspected transformation, below).
- CLL/SLL is monitored with serial laboratory studies. Routine advanced imaging is not medically necessary for monitoring treatment response or surveillance, except when initial studies reveal bulky disease involvement.
- Bulky disease is defined as lymph node mass >10cm or spleen >6cm below costal margin.

Indication	Medically Necessary Imaging Study
Initial Staging/Diagnosis	• Routine advanced imaging is not medically necessary for initial evaluation of asymptomatic individuals
For ANY of the following: • Bulky lymph node mass (>10cm) • Splenomegaly >6cm below costal margin • Presence of B symptoms • Progressive anemia and thrombocytopenia • Prior to planned systemic therapy	ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177)
Treatment Response	• For individuals with bulky nodal disease at diagnosis, CT with contrast of previously involved area(s) every 2 cycles of therapy • Routine imaging is not medically necessary for individuals without bulky nodal disease at diagnosis

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
End of Therapy Evaluation	• For individuals with bulky nodal disease at diagnosis, CT with contrast of previously involved area(s)
Suspected Progression	ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved area(s)
Suspected transformation (Richter's) from a low-grade lymphoma to a more aggressive type based on one or more of the following: • New B symptoms • Rapidly growing lymph nodes • Extranodal disease develops • Significant recent rise in LDH above normal range	• PET/CT (CPT® 78815 or CPT® 78816)
Surveillance	For individuals with bulky nodal disease at diagnosis, every 6 months for two years, then annually: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved area(s) Routine imaging is not medically necessary for individuals without bulky nodal disease at diagnosis

Evidence Discussion

Suspected/Diagnosis (whenever applicable)

- Diagnosis is by flow cytometry and biopsy. No imaging is medically necessary.[1]

Initial staging

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Routine advanced imaging for CLL/SLL is not medically necessary. However, in the interest of individual safety, to recognize mass effect and assess risk of tumor lysis syndrome prior to treatment, CT imaging of the chest, abdomen and pelvis are medically necessary. CT Neck may be added if there are neck symptoms, per general oncology guidelines.[1,12,13]

Restaging

- Routine imaging is not medically necessary unless there is bulky nodal disease, as noted in 'initial staging' section. For bulky nodal disease, treatment response imaging with CT is supported every 2 cycles or for signs and symptoms of disease progression.
- There are no data-supported benefits to routine monitoring with PET/CT, and PET/CT is significantly more radiation than CT alone. PET/CT is medically necessary only for signs and symptoms of Richter's transformation to high grade lymphoma, where the diagnosis can be made without invasive procedure using this modality.[1]

Surveillance

- There is no benefit to advanced imaging for surveillance of individuals without bulky nodal disease at diagnosis, and there is a risk of increased radiation exposure and invasive pursuit of incidental findings. In individuals with bulky nodal disease at diagnosis, flexibility is provided for surveillance imaging every 6 months for 2 years to assess for mass effect or progression.[131]

Non-Hodgkin Lymphomas – General Considerations (ONC-27.1)

ON.NH.0027.1.A
v3.0.2026

- Lymphoma is often suspected when individuals have any of the following:
  - Bulky lymphadenopathy (lymph node mass >10cm in size), hepatomegaly or splenomegaly
  - The presence of systemic symptoms (fever, drenching night sweats or unintended weight loss of >10%, called “B symptoms”)
- Individuals with AIDS-related lymphoma should be imaged according to the primary lymphoma histology.
- See: **Castleman’s Disease (unicentric and multicentric) (ONC-31.11)** for guidelines covering Castleman’s disease.
- See: **Chronic Lymphocytic Leukemia (CLL)/Small Lymphocytic Lymphoma (SLL) (ONC-26.4)** for guidelines covering Chronic Lymphocytic Leukemia (CLL)/ Small Lymphocytic Lymphoma (SLL).

Indication	Medically Necessary Imaging Study
• Biopsy proven lymphoma, or • Suspected lymphoma and any of the following: ◦ Bulky lymphadenopathy (LN mass >10cm) ◦ Hepatomegaly ◦ Splenomegaly ◦ B symptom: Unexplained fever, drenching night sweats, unintended weight loss >10% total body weight	• CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast ◦ MRI without and with contrast for individuals who cannot tolerate CT contrast due to allergy or impaired renal function
Signs or symptoms of disease involving the neck	• CT Neck with contrast (CPT® 70491)
Signs or symptoms suggesting CNS involvement with lymphoma.	• MRI Brain without and with contrast (CPT® 70553) • See: **CNS Lymphoma (also known as Microglioma) (ONC-2.7)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Known or suspected bone involvement with lymphoma	• MRI without and with contrast of symptomatic or previously involved bony areas ◦ Bone scan is inferior to MRI for evaluation of known or suspected bone involvement with lymphoma
Determine a more favorable site for biopsy when a relatively inaccessible site is contemplated	• PET/CT (CPT® 78815 or CPT® 78816) ◦ PET/CT is not medically necessary for all other indications prior to histological confirmation of lymphoma
CAR-T cell therapy	Once before treatment and once 30-60 days after completion of treatment: • PET/CT (CPT® 78815 and CPT® 78816)

Diffuse Large B Cell Lymphoma (DLBCL) (ONC-27.2)

ON.TO.0027.2.A

v3.0.2026

- Grey zone lymphomas, primary mediastinal B cell lymphomas, Grade 3 (high) follicular lymphoma, double-hit or triple-hit lymphomas, and primary cutaneous diffuse large B cell lymphoma should also be imaged according to these guidelines.

Indication	Medically Necessary Imaging Study
Initial Staging/ Diagnosis	ONE of the following:* • PET/CT (CPT® 78815 or CPT® 78816) OR • CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) *PET/CT and diagnostic CT are not medically necessary concurrently; however, if CT was performed prior to diagnosis, a PET/CT may be subsequently medically necessary.
Treatment response for all stage I, and stage II without extensive mesenteric disease	ANY of the following: • CT with contrast of previously involved area(s) may be approved every 2 cycles (6-8 weeks) of therapy • PET/CT (CPT® 78815 or CPT® 78816) after 3-4 cycles of chemotherapy (in lieu of CT or for inconclusive CT)
Treatment response for stage II WITH extensive mesenteric disease, and stages III-IV	ANY of the following: • CT with contrast of previously involved area(s) may be approved every 2 cycles (6-8 weeks) of therapy • PET/CT (CPT® 78815 or CPT® 78816) after 2-4 cycles of chemotherapy (in lieu of CT or for inconclusive CT)
End of Chemotherapy and/or Radiation Therapy Evaluation	ANY or ALL of the following: • PET/CT (CPT® 78815 or CPT® 78816) at the end of chemotherapy and again at the end of radiation • CT with contrast of previously involved area(s)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Suspected Recurrence	ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved area(s) • PET/CT can be considered in rare circumstances (e.g., bone involvement).
Biopsy-proven recurrence	• PET/CT (CPT® 78815 or CPT® 78816)
CAR-T cell therapy	Once before treatment and once 30-60 days after completion of treatment: • PET/CT (CPT® 78815 or CPT® 78816)
Surveillance for ANY of the following: • All stages of DLBCL • Relapsed lymphoma • Primary mediastinal large B cell lymphoma • Primary cutaneous diffuse large B cell lymphoma	• Every 6 months for 2 years after completion of treatment: ◦ CT Chest with contrast (CPT® 71260) ◦ CT Abdomen and Pelvis with contrast (CPT® 74177) ◦ CT with contrast of previously involved area(s)

Evidence Discussion

Initial Staging

- These guidelines for initial staging align with NCCN and support either PET/CT or diagnostic CTs. Greater than 97% of DLBCL are FDG-avid, though it is not known to be more accurate than CT for DLBCL at initial staging. However, baseline PET may be useful for comparison, as end of treatment remission assessment with PET/CT is more accurate than CT alone in DLBCL.20

Restaging

- CT is supported by NCCN every 2 cycles for restaging. PET/CT is supported by NCCN for interim restaging after 3-4 cycles of therapy and at the end of

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

chemotherapy and/or radiation for lower stage disease. For stage II with extensive mesenteric disease, stage III, and stage IV, NCCN supported PET/CT more frequently - after 2-4 cycles of therapy and at the end of therapy. PET/CT remains standard for remission assessment at end of therapy, where its accuracy is greater that CT alone for DLBCL .[1,14] Documentation of residual tissue at end of therapy is useful for monitoring for relapse, and as such diagnostic, contrast enhanced CT is medically necessary if requested in addition to PET at end of therapy .[1,14]

- FDG avidity is prognostic for relapsed/refractory DLBCL and may have a role in individual selection for CAR-T therapy and to assess response, so is medically necessary as a baseline before CAR-T and once 30-60 days after completion, to assess response and identify individuals who may be candidates for further salvage therapy .[1,14]

Surveillance

- The false-positive rate with PET scans for surveillance in various studies is 16%-20%, potentially leading to unnecessary investigations, radiation exposure, biopsies, expense, and anxiety.[3,13] Several small studies have failed to note an improvement in relapse detection with CT over clinical observation in DLBCL; however, there is no definitive standard for surveillance imaging with CT.[5,6] The majority of relapses occur in the first 2 years, and the NCCN supported CT imaging of involved areas and chest, abdomen, and pelvis every 6 months for the first two year. In the interest of individual- and provider-centricity, these guidelines align with the NCCN with respect to surveillance in DLBCL.[1]

Follicular Lymphoma (ONC-27.3)

ON.NH.0027.3.A
v3.0.2026

- This section applies to follicular lymphomas with WHO grade of 1 (low) or 2 (intermediate) and primary cutaneous follicle center lymphoma. Grade 3 (high) follicular lymphomas should be imaged according to guidelines found in: **Diffuse Large B Cell Lymphoma (DLBCL) (ONC-27.2)**.

Indication	Medically Necessary Imaging Study
Initial Staging/Diagnosis	EITHER of the following: • CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) OR • PET/CT (CPT® 78815)
For ANY of the following, if PET/CT has not yet been performed: • If radiation therapy is being considered for stage I or II disease • CT results lead to a plan for systemic therapy	• PET/CT (CPT® 78815 or CPT® 78816)
Treatment Response	• CT with contrast of previously involved area(s) every 2 cycles of therapy
End of Therapy Evaluation	ONE of the following may be approved: • PET/CT (CPT® 78815 or CPT® 78816) OR • CT Chest with contrast (CPT® 71260) and • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved area(s)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Suspected Recurrence	ANY or ALL of the following may be approved: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved area(s)
Suspected transformation (Richter's) from a low grade lymphoma to a more aggressive type based on one or more of the following: • New B symptoms • Rapidly growing lymph nodes • Extranodal disease develops • Significant recent rise in LDH above normal range	• PET/CT (CPT® 78815 or CPT® 78816)
Surveillance for ANY of the following: • After completion of active treatment • On maintenance treatment • Observation without any treatment	For all stages, every 6 months for two years, then annually: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved area(s)
Surveillance of pediatric-type follicular lymphoma in adults	Routine advanced imaging is not medically necessary after complete response

Evidence Discussion

Initial Staging

Diagnostic quality CT with contrast or PET/CT may be used for initial staging. Clinical stage is modified in only 15-20% of individuals with use of PET/CT and results in a change in treatment in only 8% of individuals.[1] A baseline PET/CT is useful for comparison for treatment response and to determine if further treatment intensification is necessary and is recommended if systemic therapy is planned. PET/CT is particularly important in the setting of localized disease with a plan for radiation therapy only to rule out any other systemic disease and to serve as a baseline for treatment response.[1,3,4,20]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Restaging

PET/CT is of unclear utility for interim restaging, as interim PET/CT response shows no association with overall survival; thus, conventional CT is medically necessary.[21] PET/CT does identify individuals at risk of progression at end of induction therapy, where initial studies showed that 69% of individuals who were classified as not having complete remission on CT were re-classified as complete metabolic remission when staged with PET/CT at end of induction.[20] This increased sensitivity and specificity more accurately identifies individuals at risk of poor progression-free survival who may be candidates for consolidative therapy and prevents over and under-treatment. These results only apply to end of induction PET/CT.[1,4,20]

While PET/CT alone is not sufficient to diagnose transformation of follicular lymphoma to diffuse large B cell lymphoma, when clinical signs and symptoms and lab values suggest transformation, PET/CT can be useful to detect transformation. SUV >10 predicts aggressive lymphoma with 80% certainty and PPV increases at higher SUVs.[1,18] FDG avidity is also standard of care to select biopsy site in suspected transformation.[1,18]

Surveillance

There are little data on the role of surveillance imaging in indolent lymphomas including follicular lymphoma. The majority of relapses occur within the first 2 years post completion of therapy, and these guidelines align with the NCCN support of CT no more than every 6 months in the first two years and no more than annually following. Given that indolent lymphoma is considered a chronic condition, there is no endpoint for this imaging if requested.[1] The exception is pediatric-type follicular lymphoma, for which there is no survival benefit with detection of recurrence via surveillance imaging vs clinical detection; surveillance imaging is not medically necessary in this population.[1,13] PET/CT surveillance is generally not medically necessary, due to a false positive rate as high as 20%, with no documented survival benefit, and increased radiation, invasive procedures, anxiety and cost.[13]

Marginal Zone Lymphomas (ONC-27.4)

ON.NH.0027.4.A
v3.0.2026

- MALT lymphomas in any location and primary cutaneous marginal zone lymphoma should also be imaged according to these guidelines.
- Splenic Marginal Zone Lymphoma is diagnosed with splenomegaly, peripheral blood flow cytometry and bone marrow biopsy. Splenectomy is diagnostic and therapeutic. PET scan is not routinely medically necessary prior to splenectomy.

Indication	Medically Necessary Imaging Study
Initial Staging/ Diagnosis	ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177)
EITHER of the following: • If radiation therapy is being considered for stage I or II disease • If systemic therapy is planned	• PET/CT (CPT® 78815 or CPT® 78816)
Treatment Response	• CT with contrast of previously involved area(s) every 2 cycles of therapy
End of Therapy Evaluation	ONE of the following: • CT with contrast of previously involved area(s) • PET/CT (CPT® 78815 or CPT® 78816)
Suspected Recurrence	ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved area(s)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Suspected recurrence and ANY of the following: • Symptoms of end organ dysfunction • Clinically significant or progressive cytopenias • Bulky disease (single mass of ≥7cm or ≥3 or more nodal sites 3cm in diameter) • Steady or rapid progression	In addition to the CT imaging above: • PET/CT (CPT® 78815 or CPT® 78816)
Surveillance of all stages of nodal marginal zone lymphoma for any of the following: • After completion of active treatment • On maintenance treatment • Observation without any treatment	Every 6 months for two years, then annually: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved area(s)
Surveillance of all stages of extranodal marginal zone lymphoma	Advanced imaging is not routinely medically necessary for surveillance of asymptomatic individuals

Evidence Discussion

Initial Staging

Diagnostic, contrasted CT of chest, abdomen and pelvis is medically necessary for all individuals to assess extent of disease. PET avidity of extranodal marginal zone lymphoma is unreliable, as only 50%-75% of these tumors are FDG avid.[4] A baseline

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

PET/CT is useful for comparison for treatment response and to determine if further treatment intensification is necessary, and so is medically necessary if systemic therapy is planned. PET/CT is particularly important in the setting of localized disease with a plan for RT only, to rule out any other systemic disease and to serve as a baseline for treatment response.[1,3,4]

Restaging

There is no clear role for PET in interim restaging of marginal zone lymphoma; CT is medically necessary every 2 cycles in alignment with NCCN. End of therapy PET/CT is medically necessary to identify individuals without a complete metabolic response who are candidates for extended therapy, to prevent over- or under- treatment.[1,4]

Surveillance

There are little data on the role of surveillance imaging in indolent lymphomas including marginal zone lymphoma. Extranodal marginal zone lymphoma typically remains localized, and asymptomatic surveillance with advanced imaging is not medically necessary.[19] The majority of relapses occur within the first 2 years post completion of therapy. These guidelines align with NCCN support of CT no more than every 6 months in the first two years and no more than annually following. Given that indolent lymphoma is considered a chronic condition, there is no endpoint for this imaging if requested.[1] PET/CT surveillance is not universally medically necessary, due to a false positive rate as high as 20%, with no documented survival benefit, and increased radiation, invasive procedures, anxiety, and cost.[13] However, PET/CT is a medically necessary imaging modality for specific circumstances of recurrence; NCCN supported PET/CT in recurrence when there are indications for treatment.[1]

Mantle Cell Lymphoma (ONC-27.5)

ON.NH.0027.5.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Initial Staging/Diagnosis	ONE of the following: • CT Chest with contrast (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) OR • PET/CT (CPT® 78815 or CPT® 78816)
Treatment Response	• PET/CT (CPT® 78815 or CPT® 78816) or CT with contrast of previously involved area(s) every 2-4 cycles of therapy
End of Therapy Evaluation	ONE of the following: • CT with contrast of previously involved area(s) • PET/CT (CPT® 78815 or CPT® 78816)
Suspected Recurrence	ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved area(s) • PET/CT can be considered in rare circumstances (e.g., bone involvement).
Surveillance for all stages	Every 6 months for 2 years, and then annually: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved area(s)

Evidence Discussion

Initial Staging

Diagnostic CT with contrast or PET/CT is medically necessary. PET/CT is the preferred modality particularly when systemic therapy is planned in order to prevent under treatment.[1,20]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Restaging

Interim restaging with PET/CT has not been shown to change outcomes; thus, CT alone is medically necessary every two cycles unless the sites of disease are only visible on PET/CT. However, PET/CT is medically necessary at end of planned therapy as a lack of complete metabolic response may require maintenance treatment .[1]

Surveillance

Late relapses, as far as 15 years out, can occur with mantle cell lymphoma. The benefit of detection of with imaging vs clinical detection remains unclear, and some studies have shown no significant advantage in survival for relapses after first remission detected by surveillance imaging.[28] However, this is still an active point for discussion among treating providers, and the NCCN supported surveillance imaging with CT scan.[1,28] Given that most providers consider NCCN the standard of care, this guideline aligns with the more conservative NCCN recommended timeframe, to acknowledge this data while maintaining an individual- and provider-centric approach. Surveillance scanning with PET/CT has a positive predictive value of only 24% in this entity and is not medically necessary.[1,28]

Burkitt's Lymphomas (ONC-27.6)

ON.NH.0027.6.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Initial Staging/Diagnosis	ANY or ALL of the following: • PET/CT (CPT® 78815 or CPT® 78816) • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177)
Treatment Response	• CT with contrast of previously involved area(s) every 2 cycles of therapy • PET/CT is not medically necessary for monitoring treatment response but can be considered in rare circumstances when CT did not show disease (e.g., bone).
End of Therapy Evaluation	ANY or ALL of the following: • PET/CT (CPT® 78815 or CPT® 78816) at the end of chemotherapy and again at the end of radiation • CT with contrast of previously involved area(s)
Suspected Recurrence	ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved area(s) • PET/CT can be considered in rare circumstances (e.g., bone involvement).
Surveillance	Every 6 months for 2 years after completion of treatment: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177)

Evidence Discussion

Initial Staging/Diagnosis

In alignment with NCCN, both diagnostic quality CT scan with contrast and PET/CT are medically necessary in Burkitt's Lymphoma. Diagnostic, contrasted CT is helpful

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

for clarifying node bulk (individual nodes vs. conglomerates), anatomic relationships of bulky disease, abdominal and Waldeyer's ring involvement, as well as abdominal visceral involvement, all of which are relevant to treatment decisions and emergency management in Burkitt's lymphoma. Baseline metabolic activity is useful for comparison at end of therapy, where FDG avidity defines treatment response.[1,3]

Treatment Response

CT alone (rather than PET/CT) should be used to assess response between cycles, as complete response is not defined until completion of upfront therapy regimen. At the end of all planned upfront therapy, a PET/CT is medically necessary, even in addition to diagnostic contrasted CTs. Metabolic response at this time point determines whether therapy can be considered complete or whether local therapy or intensification of treatment will be necessary.[1,3,4]

Surveillance

The role of surveillance in Burkitt's Lymphoma is somewhat controversial. Clinically evident symptoms of recurrence develop quickly in this aggressive entity, and recurrence is as likely to be diagnosed based on symptoms as by surveillance imaging in some studies. PET/CT surveillance of Burkitt's Lymphoma is widely discouraged as it increases false positive findings, radiation exposure, and does not improve outcomes .[4,13] NCCN is considered the standard for care in the U.S., and NCCN supported CT with contrast every 6 months for 2 years, with which these guidelines align for an individual- and provider-centric approach. Relapse after 2 years is rare, imaging after this point for asymptomatic surveillance has not been shown to improve outcomes.[1,13]

T Cell Lymphomas (ONC-27.8)

ON.NH.0027.8.A
v3.0.2026

- Includes Peripheral T-Cell Lymphomas, Mycosis Fungoides/Sézary Syndrome, Anaplastic Large Cell Lymphoma (ALCL) including breast implant-associated ALCL, Angioimmunoblastic lymphoma, and Primary Cutaneous CD30+T Cell Lymphoproliferative Disorders

Indication	Medically Necessary Imaging Study
Initial Staging/ Diagnosis	ANY or ALL of the following: • PET/CT (CPT® 78815 or CPT® 78816) • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177)
T-cell lymphoma of nasal cavity, oropharynx, or nasopharynx	In addition to the imaging above: • MRI Orbits, Face, and Neck without and with contrast (CPT® 70543)
Breast implant-associated ALCL	In addition to the above initial staging studies: • Ultrasound Breast (CPT® 76641 or CPT® 76642) ◦ MRI Breast (CPT® 77049) for evaluation of inconclusive ultrasound findings
Treatment Response	Any ONE of the following after 3-4 cycles: • PET/CT (CPT® 78815 or 78816) or • CT Chest with contrast (CPT® 71260), and • CT Abdomen and Pelvis with contrast (CPT® 74177) and • CT with contrast of previously involved area(s)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
End of Therapy Evaluation	Any ONE of the following at the end of chemotherapy and again at the end of radiation therapy: • PET/CT (CPT® 78815 or CPT® 78816) or • CT Chest with contrast (CPT® 71260), and • CT Abdomen and Pelvis with contrast (CPT® 74177), and • CT with contrast of previously involved area(s)
Suspected Recurrence	ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved area(s) • PET/CT can be considered in rare circumstances (e.g., bone involvement).
Surveillance, all stages	Every 6 months for 2 years, then annually for 5 years: • CT Chest with contrast (CPT® 71260), CT Abdomen and Pelvis with contrast (CPT® 74177), and CT of previously involved areas ◦ PET/CT (CPT® 78815 or CPT® 78816) is medically necessary instead of CT for individuals with a history of extranodal disease that was not adequately imaged by conventional imaging

Evidence Discussion

Initial Staging

FDG PET/CT fusion (PET with attenuation CT) is valuable for initial staging as individuals with T-cell lymphoma often have extranodal disease, which may be missed on body area specific diagnostic CTs. Noncontiguous nodes, Waldeyer ring, and GI/liver involvement is also common in T-cell lymphomas and may be difficult to distinguish on PET/CT fusion studies alone; thus, our guidelines support the use of diagnostic quality, contrasted CTs when requested to ensure correct staging and treatment stratification and prevent under- or over-treatment, in addition to PET/CT fusion imaging.[1,2,29]

Treatment Response

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Modality for restaging should be determined by which studies best illustrated disease at initial staging. PET/CT fusion imaging or body area specific diagnostic quality, contrasted CTs are generally adequate for comparison to initial staging to assess response[2] after 3-4 cycles and again at end of chemotherapy and at end of radiation. Imaging prior to 3-4 cycles may result in over- or under-treatment, and thus is not medically necessary.[1,2]

Surveillance

There is no evidence illustrating an overall survival advantage in detection of relapse from imaging vs. clinical detection, but data suggests better progression-free survival after second line treatment in individuals undergoing imaging surveillance.[13] Considering these perspectives and to align with NCCN, CT of viscera and all previously involved areas is medically necessary every 6 months for 2 years, then annually for 5 years.[2] PET/CT surveillance is not medically necessary as no survival improvement is noted with PET/CT surveillance, and it subjects individuals to increased radiation, increased costs, and increased risk of invasive procedures for incidental findings, as the false positive rate in this setting is as high as 20%.[13,20] CT is generally medically necessary for suspected recurrence as well, with PET reserved for biopsy-proven recurrence, by the same rationale.

Post-Transplant Lymphoproliferative Disorders (ONC-27.9)

ON.NH.0027.9.A
v3.0.2026

- Post-transplant lymphoproliferative disorder (PTLD) or viral-associated lymphoproliferative disorder can rarely occur following solid organ or hematopoietic stem cell transplantation, or in primary immunodeficiency. When reduction of immunosuppression is unsuccessful, these are often treated with chemoimmunotherapy similar to high-grade NHL.
- This section applies to Monomorphic (B-cell type) PTLD and Polymorphic PTLD.
- For Hodgkin-lymphoma subtype of PTLD, see: **Hodgkin Lymphomas (ONC-28)** for imaging recommendations.

Indication	Medically Necessary Imaging Study
Initial Staging/ Diagnosis	ANY or ALL of the following: • PET/CT (CPT® 78815 or CPT® 78816) • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177)
Treatment Response	ANY or ALL of the following after 4 weeks of reducing immunosuppression or every 2 cycles (6-8 weeks) of chemo/ immunotherapy: • CT Chest with contrast (CPT® 71260), and • CT Abdomen and Pelvis with contrast (CPT® 74177), and • CT with contrast of previously involved area(s)
End of Therapy Evaluation	ANY one of the following at the end of treatment: • PET/CT (CPT® 78815 or CPT® 78816) or • CT Chest with contrast (CPT® 71260), and • CT Abdomen and Pelvis with contrast (CPT® 74177), and • CT with contrast of previously involved area(s)
Suspected recurrence	• CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Surveillance	No advanced imaging for surveillance

Evidence Discussion

Initial staging

FDG PET/CT fusion (PET with attenuation CT) is valuable for initial staging as individuals with PTLD often have extranodal and/or multi-site disease, which may be missed on body area specific diagnostic CTs. Individuals with single sites of disease may be managed with local treatment alone; thus, thorough assessment for systemic disease is essential to prevent under-treatment. Node bulk has prognostic value and is used for treatment stratification, and bulky masses vs noncontiguous nodes may be difficult to distinguish on PET/CT fusion studies alone. These guidelines thus support the use of diagnostic quality, contrasted CTs when requested in addition to PET/CT fusion imaging.[1,29]

Restaging

Restaging with CT is medically necessary every 2 cycles of chemotherapy as is standard for most disease processes.[1] Median time to failure of reduction of immunosuppression as first line therapy, however, is only 45 days, so for individual safety, these guidelines support earlier restaging in this scenario as soon as 4 weeks after reduction of immunosuppression.[22] Changing therapy based on interim PET/CT alone is not medically necessary, and thus, our guidelines support CT alone for interim restaging, with biopsy for concerning findings.[1,3,4] These guidelines do support PET/CT at end of planned treatment to ensure a complete metabolic response.[1,3,4] Concurrent diagnostic CTs may be done in lieu of PET/CT if requested, but diagnostic CTs in addition to PET/CT fusion studies do not offer additional information in the setting of a complete metabolic response .[3,4]

Surveillance

Advanced imaging surveillance is not medically necessary for PTLD.[1,13] Surveillance imaging has not been shown to improve outcomes for PTLD and it subjects individuals to increased radiation, increased costs, and increased risk of invasive procedures for incidental findings.[13] Surveillance is predominantly via EBV PCR.[1]

Waldenström Macroglobulinemia or Lymphoplasmacytic Lymphoma (ONC-27.10)

ON.NH.0027.10.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Initial Staging/Diagnosis	ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • PET/CT (CPT® 78815 or CPT® 78816)
Treatment Response	• CT with contrast of previously involved area(s) every 2 cycles of therapy
End of Therapy Evaluation	• CT with contrast of previously involved area(s)
Suspected Recurrence	ANY or ALL of the following: • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved area(s)
Surveillance	No advanced imaging for surveillance

Evidence Discussion

Initial Staging

NCCN supported contrasted CT of chest, abdomen, and pelvis.[14,17] PET/CT fusion is recommended equally with diagnostic CT by the NCCN.[14]

Restaging

NCCN supported contrasted, diagnostic quality CTs every 2 cycles of chemotherapy and at end of treatment to determine response and prevent under-treatment. Diagnostic, contrasted CTs of chest, abdomen, pelvis and previously involved areas are medically necessary for suspected recurrence.[14,17] PET/CT is not consistently correlated with

monoclonal protein response, which is the primary means of monitoring this entity, and PET/CT is not recommended for restaging of this entity.[14,15,16]

Surveillance

Surveillance of lymphoplasmacytic lymphoma is based on laboratory monitoring of blood counts and chemistries, serum proteins, and immunoglobulins. There is no established role for imaging surveillance in this entity.[14,16]

Hodgkin Lymphoma – General Considerations (ONC-28.1)

ON.HL.0028.1.A
v3.0.2026

- Lymphoma is often suspected when individuals have any of the following:
  - Bulky lymphadenopathy (lymph node mass >10cm in size), hepatomegaly or splenomegaly
  - The presence of systemic symptoms (fever, drenching night sweats or unintended weight loss of >10%, called “B symptoms”)
- Individuals with AIDS-related lymphoma should be imaged according to the primary lymphoma histology.
- The **Deauville Criteria** are internationally accepted criteria, which utilize a 5-point scoring system for the FDG avidity of a Hodgkin's lymphoma or Non-Hodgkin's lymphoma tumor mass as seen on FDG PET.
  - Score 1: No uptake above the background
  - Score 2: Uptake ≤mediastinum
  - Score 3: Uptake >mediastinum but ≤liver
  - Score 4: Uptake moderately increased compared to the liver at any site
  - Score 5: Uptake markedly increased compared to the liver at any site
  - Score X: New areas of uptake unlikely to be related to lymphoma

Indication	Medically Necessary Imaging Study
• Biopsy proven lymphoma, or • Suspected lymphoma and any one of the following: ◦ Bulky lymphadenopathy (LN mass >10cm) ◦ Hepatomegaly ◦ Splenomegaly ◦ B symptom: Unexplained fever, drenching night sweats, unintended weight loss >10% total body weight	• CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast ◦ MRI without and with contrast for individuals who cannot tolerate CT contrast due to allergy or impaired renal function
Signs or symptoms of disease involving the neck	• CT Neck with contrast (CPT® 70491)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Signs or symptoms suggesting CNS involvement with lymphoma	• MRI Brain without and with contrast (CPT® 70553) • See: **CNS Lymphoma (also known as Microglioma) (ONC-2.7)**
Known or suspected bone involvement with lymphoma	• MRI without and with contrast of symptomatic or previously involved bony areas ◦ Bone scan is inferior to MRI for evaluation of known or suspected bone involvement with lymphoma
Determine a more favorable site for biopsy when a relatively inaccessible site is contemplated	• PET/CT (CPT® 78815 or CPT® 78816) ◦ PET/CT not medically necessary for all other indications prior to histological confirmation of lymphoma
CAR-T cell therapy	Once before treatment and once 30-60 days after completion of treatment: • PET/CT (CPT® 78815 or CPT® 78816)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Classical Hodgkin Lymphoma (ONC-28.2)

ON.HL.0028.2.A

v3.0.2026

- This section applies to nodular sclerosis, mixed cellularity, lymphocyte-depleted and lymphocyte-rich subtypes of Hodgkin lymphoma.
- Pregnancy-specific considerations: US Abdomen (CPT® 76700) or MRI Abdomen without contrast (CPT® 74181) and MRI Pelvis without contrast (CPT® 72195) are medically necessary in lieu of PET/CT or CT imaging.
  - MRI Abdomen and MRI Pelvis may be performed after US Abdomen if staging is unclear on US.

Indication	Medically Necessary Imaging Study
Initial Staging/Diagnosis	ANY or ALL of the following: • PET/CT (CPT® 78815 or CPT® 78816) • CT Neck with contrast (CPT® 70491) • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177)
Prior to initiation of therapy if one month or more has passed since previous PET/CT was performed	• PET/CT (CPT® 78815 or CPT® 78816)
Treatment Response	• PET/CT (CPT® 78815 or CPT® 78816) as frequently as every 2 cycles
End of Chemotherapy and/or Radiation Therapy Evaluation	• PET/CT (CPT® 78815 or CPT® 78816) at the end of chemotherapy and again at the end of radiation (at least 12 weeks after completion of radiation therapy)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Suspected or biopsy proven recurrence	ANY or ALL of the following: • CT Neck with contrast (CPT® 70491) • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved area(s) • PET/CT (CPT® 78815 or CPT® 78816) if suspected recurrence ≥3 months after completion of therapy
Surveillance	ANY or ALL of the following, every 6 months for 2 years after completion of therapy: • CT Neck with contrast (CPT® 70491) • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved area(s) In addition to the above studies: • A single follow-up PET/CT at three months if end of therapy PET/CT shows Deauville 4 or 5 FDG avidity

Proprietary Information of UnitedHealthcare.

Nodular Lymphocyte – Predominant Hodgkin Lymphoma (ONC-28.3)

ON.HL.0028.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Initial Staging/Diagnosis	ANY or ALL of the following: • PET/CT (CPT® 78815 or CPT® 78816) • CT Neck with contrast (CPT® 70491) • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177)
Treatment Response	• CT with contrast of previously involved areas as frequently as every 2 cycles
End of Chemotherapy and/or Radiation Therapy Evaluation	• PET/CT (CPT® 78815 or CPT® 78816) at the end of chemotherapy and again at the end of radiation (at least 12 weeks after completion of radiation therapy)
Suspected Recurrence	ANY or ALL of the following: • CT Neck with contrast (CPT® 70491) • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved area(s)
Biopsy proven recurrence	• PET/CT (CPT® 78815 or CPT® 78816)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Suspected transformation (Richter's) from a low-grade lymphoma to a more aggressive type based on one or more of the following: • New B symptoms • Rapidly growing lymph nodes • Extranodal disease develops • Significant recent rise in LDH above normal range	• PET/CT (CPT® 78815 or CPT® 78816)
Surveillance	ANY or ALL of the following every 6 months for 2 years after completion of therapy: • CT Neck with contrast (CPT® 70491) • CT Chest with contrast (CPT® 71260) • CT Abdomen and Pelvis with contrast (CPT® 74177) • CT with contrast of previously involved area(s) In addition to the above studies: • A single follow-up PET/CT at three months if end of therapy PET/CT shows Deauville 4 or 5 FDG avidity

Evidence Discussion

Initial staging and Restaging

PET imaging is useful for staging, prognosis, and treatment stratification in all subtypes of Hodgkin Lymphoma. Staging with PET/CT rather than CT often confirms a higher stage of disease. While overall survival outcome is not clearly improved by staging/restaging with PET/CT, stratification of treatment based on PET/CT benefits individuals by preventing over- and under-treatment. PET is thus medically necessary for initial staging, re-staging every 2 cycles, and at the end of therapy. False-positive rates are elevated in the weeks following radiation, reaching up to 20%. Decisions based on scans done in close proximity to radiation may result in over-treatment. Therefore, PET/CT should not be performed until 12 weeks after completion of radiation.[1,2,11]

Diagnostic CT with contrast is medically necessary concurrently with PET/CT for initial staging as it may better differentiate nodal conglomerates from individual nodes in

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

close proximity, and node bulk is prognostic and also used for treatment stratification. However, performing diagnostic CTs concurrently with PET/CT at restaging does not provide a benefit, as FDG avidity is highly indicative of response in Hodgkin lymphoma, where CT alone may over- or under- estimate response. FDG avidity guides response assessment and informs subsequent treatment decisions. This includes intensifying therapy if PET avidity persists after 2-4 cycles, or omitting consolidative radiotherapy in cases of good response on PET/CT after 4 cycles for low-stage disease. A complete metabolic response (Deauville score of 3 or less) should be confirmed to determine the end of treatment. If the end-of-therapy PET/CT shows a Deauville score of 4-5, repeating the PET/CT 3 months later is medically necessary to confirm the metabolic status of residual masses and to prevent under-treatment.[1,2,11]

While PET/MRI shows high concordance with PET/CT at a decreased radiation dose, it is inferior for assessing disease in the lungs, more time-consuming, and more costly. Furthermore, it has not been established as a standard for treatment stratification in adult Hodgkin Lymphoma and is therefore not recommended over PET/CT.[6]

Surveillance

Surveillance imaging with PET/CT is not medically necessary, as the false-positive rate with PET scans in this context is greater than 20%, leading to unnecessary investigations, radiation exposure, biopsies, expense, and individual anxiety. In addition, no statistically significant difference in survival has been noted with CT surveillance imaging in Hodgkin Lymphoma, despite a statistically significant increase in radiation exposure and cost. However, given that many existing protocols still require surveillance imaging, the NCCN continued to support CT surveillance every 6 months in the first two years post therapy if requested. Given that NCCN is viewed as the standard of care in most U.S. oncology treatment centers, this guideline aligns with this current NCCN recommendation for an individual- and provider-centric approach.[1,2,4]

General Considerations for Stem Cell Transplant (ONC-29.1)

ON.HT.0029.1.A
v3.0.2026

Transplant Types:

Allogeneic ("allo"): The donor and recipient are different people, and there are multiple types depending on the source of the stem cells and degree of match between donor and recipient. This is most commonly used in diseases originating in the hematopoietic system, such as leukemias and lymphomas, and bone marrow failure syndromes or metabolic disorders. Common types are:

- Matched sibling donor (MSD or MRD): Donor and recipient are full siblings and HLA-matched
- Matched unrelated donor (MUD): Donor and recipient are HLA matched but not related to each other
- Cord blood: Donor stem cells come from frozen umbilical cord blood not related to the recipient, sometimes from multiple different donors at once
- Haploidentical transplant (haplo): Donor is a half-HLA match to the recipient, usually a parent

Autologous ("auto"): The donor and recipient are the same person. The process involves delivery of high dose chemotherapy that is ablative to the bone marrow, followed by an infusion of one's own harvested stem cells.

Allogeneic HSCT results in a much greater degree of immunosuppression than autologous HSCT because of the need to allow the new immune system to chimerize with the recipient's body. Immune reconstitution commonly takes more than a year for individuals who receive allogeneic HSCT, and individuals remain at high-risk for invasive infections until that has occurred.

Pre-Transplant Imaging in HSCT:

- Pre-transplant imaging in HSCT generally takes place within 30 days prior to transplant and involves a reassessment of the individual's disease status as well as infectious disease clearance.

Indication	Medically Necessary Imaging Study
Immediate pre-transplant period	• CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) for ANY of the following: ◦ Any individual prior to undergoing allogeneic transplant ◦ New findings on chest x-ray ◦ New/worsening signs/symptoms of chest involvement • CT Sinus (CPT® 70486) for any clinical signs or symptoms • CT of other body areas is not medically necessary without clinical signs or symptoms of involvement
Assess cardiac function	• Echocardiogram (CPT® 93306, CPT® 93307 or CPT® 93308) ◦ MUGA scan (CPT® 78472) in specific circumstances, see: **Oncologic Indications for Cancer Therapeutics-Related Cardiac Dysfunction (CTRCD) (CD-12.1)** in the Cardiac Imaging Guidelines
Assess pulmonary function	• Pulmonary function tests
Assess primary disease status	• See disease-specific guidelines for end of therapy response assessment

Post-Transplant Imaging in HSCT:

- There are many common complications from HSCT, including infection, acute and chronic graft versus host disease (GVHD), hepatic sinusoidal obstruction syndrome, and restrictive lung disease, among others.
- Disease response generally takes place at ~Day +30 (autos and some allos) or ~Day +100 (allos) post-transplant.

Indication	Medically Necessary Imaging Study
Assess known or suspected HSCT complications	• Site-specific imaging

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Suspected hepatic GVHD (elevated liver enzymes)	• Abdominal US (CPT® 76700 or CPT® 76705)
Suspected Bronchiolitis Obliterans Syndrome (BOS)	• CT Chest without contrast (CPT® 71250)
Assess primary disease status post-transplant	• See disease-specific guidelines for end of therapy evaluation and surveillance
Individuals receiving tandem auto transplants (2-4 autos back-to-back, spaced 6 to 8 weeks apart)	• Guideline recommended imaging repeated after each transplant

Evidence Discussion

Pre-Transplant imaging in Hematopoietic Stem Cell Transplant (HSCT)

This refers to imaging in the immediate pre-transplant period, approximately 30 days prior to anticipated HSCT. There is not a clear consensus for pre-transplant infectious screening with imaging, but a CT Chest and CT Sinus are medically necessary for any clinical signs and symptoms of respiratory or sinus infection. NCCN does not support CT imaging for infection screening in asymptomatic individuals.[1] There are no clear data to support pre-transplant sinus imaging in adults; extrapolation from pediatric data shows no change in pre-transplantation management nor prediction of post-transplant sinusitis based on pre-transplant imaging of asymptomatic individuals.[2,3] Screening for infection of abdomen and pelvis with advanced imaging is not medically necessary as it has not been shown to change management or outcomes yet increases cost and radiation exposure.[1,4] Echocardiogram is medically necessary prior to transplant conditioning for all individuals, to assure the safest possible dosing for cardiotoxic agents. MUGA scan is medically necessary to supplement echocardiogram in individuals with a previous low ejection fraction (LVEF <50%).[5]

Post-Transplant imaging in HSCT

Timing of post-transplant disease restaging varies by disease process. Generally, repeat imaging follows the disease-specific guidelines for end of therapy evaluation and surveillance. For individuals receiving tandem auto transplants, disease-specific imaging can be repeated after each transplant. Imaging for post-transplant complications maximizes safety and allows for early intervention.

Fever of Unknown Origin (FUO) (ONC-30.1)

ON.MC.0030.1.A
v3.0.2026

- FUO is defined as a persistent fever ≥101°F and ≥3 weeks with unidentified cause.
- While fever is a classic "B" symptom of advanced lymphoma, a cancer-related fever presenting in isolation without any other signs or symptoms of neoplastic disease is rare.

Indication	Medically Necessary Imaging Study
If physical examination, chest x-ray, and laboratory studies are non-diagnostic	• Echocardiogram (CPT® 93306) • Abdominal ultrasound (CPT® 76700) • MRI Brain without and with contrast (CPT® 70553)
Above studies (including PE/ENT exam, pelvic exam, and DRE with laboratory studies) have failed to demonstrate site of infection	• CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast • Radiopharmaceutical localization of tumor or distribution of radiopharmaceutical agent(s): CPT® 78800, CPT® 78801, or CPT® 78802, CPT® 78804, CPT® 78803 or CPT® 78831 (SPECT), or CPT® 78830, or CPT® 78832 (SPECT/CT)
"B" symptoms	• See: **Non-Hodgkin Lymphomas (ONC-27)**
Any CNS sign/symptom accompanied by fever	• MRI Brain without and with contrast (CPT® 70553)
All individuals	• PET is not medically necessary in the work-up of individuals with FUO

Evidence Discussion

The widely accepted definition of "Fever of Unknown Origin" (FUO) is persistent fever of at least 101 degrees F for at least 3 weeks with unidentified cause. Most published recommendations are based on expert consensus rather than data. Malignancy accounts for 20%-30% of FUO in adults.[14,15] The remainder are infectious, inflammatory, and immune mediated. Physical exam, chest x-ray, and laboratory

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

findings including workup for specific infections should guide workup, and all routine age-based cancer screening should be complete. If these are negative, further workup may be medically necessary. Echocardiogram, abdominal ultrasound, and MRI Brain without and with contrast are medically necessary, with sensitivity rates of 80%-86%, as abdominal and pelvic abscess, endocarditis, and viral and bacterial CNS processes remain more common causes of fever than malignancy.[14,15,16,17] These modalities limit radiation exposure and are recommended as first line imaging in most algorithms.[14,15,16,17]

If the above workup has not demonstrated a source of infection, CT with contrast of the chest, abdomen and pelvis is medically necessary as second line imaging, with sensitivity of up to 90% and specificity up to 70% for determining the cause of fever.[14,15] Technitium-based scans are insensitive but highly specific (93%-94%), with the advantage of lower radiation exposure than CT, and are medically necessary to localize infectious or inflammatory foci.[14,18,21] MRI Brain without and with contrast is medically necessary for any CNS symptoms accompanied by fever, as supported by several FUO algorithms and as outlined in HD-14.1 CNS and Head Infection. B symptoms with concern for lymphoma also warrant CTs, with further details outlined in EviCore ONC-27.1. The utility of PET/CT in workup of FUO is emerging, but specificity is variable, ranging from 52%-85%.[16,17,19-22] At this time it is not medically necessary in the workup of FUO.

Unexplained Weight Loss (ONC-30.2)

ON.MC.0030.2.A
v3.0.2026

- Unintentional weight loss is defined as loss of ≥10 lbs. or ≥5% of body weight over 6 months or less, without an identifiable reason.
- Initial workup for all individuals may include appropriate detailed history, physical exam, baseline laboratory studies (e.g., CBC, CMP, HgbA1c, ESR/CRP, infectious workup, stool hemoccult, endocrine evaluation to rule out thyroid, pituitary, or gonadal dysfunction, etc.), chest x-ray, age-appropriate cancer screening, and neurological evaluation to rule out depression/dementia.
- Additional workup is directed to evaluate specific signs, symptoms, red flags, or abnormalities detected on initial workup. See condition-specific imaging guidelines for additional details.
- PET is not medically necessary in the work-up of individuals with unexplained weight loss.
- Being on a GLP-1 does not preclude a workup for unexplained weight loss. If provider believes the individual's weight loss is not fully explained by the GLP-1, these guidelines should be used to guide imaging as for all other individuals.

Indication	Medically Necessary Imaging Study
CNS symptoms or abnormal pituitary hormones	• MRI Brain or Sella Turcica without and with contrast (CPT® 70553)
Abnormal thyroid function	• Thyroid ultrasound (CPT® 76536)
Abnormal liver function	• Abdominal ultrasound (CPT® 76700)
Abnormal kidney function	• Ultrasound Kidney and Bladder (CPT® 76770 or CPT® 76775)
Suspected cardiac dysfunction	• Echocardiogram (CPT® 93306)
Non-smokers	• Chest x-ray ◦ CT Chest with contrast (CPT® 71260) to evaluate abnormalities on chest x-ray
Current or former smokers	• CT Chest with contrast (CPT® 71260)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Dysphagia or early satiety	See: **Dysphagia and Esophageal Disorders (NECK-3)**
GI bleeding	See: **GI Bleeding (AB-22)**
Abdominal pain without red flag signs	See: **Abdominal Pain (AB-2)**
Suspected pancreatic cancer in individuals aged ≥60 years with weight loss and at least one of the following[13]: • Diarrhea • Back pain • Abdominal pain • Nausea/vomiting • Constipation • New onset diabetes • Abnormal labs (CA 19-9, LFTs) • Non-diagnostic or negative abdominal ultrasound	Any ONE of the following: • CT Abdomen with contrast (CPT® 74160) • CT Abdomen and Pelvis with contrast (CPT® 74177) • MRI Abdomen without and with contrast (CPT® 74183) See also: **Epigastric Pain and Dyspepsia (AB-2.5)**
If all of the above do not identify cause of weight loss	Any of the following, if not previously performed: • CT Chest (CPT® 71260) • CT Abdomen and Pelvis (CPT® 74177) with contrast

Evidence Discussion

Gradual weight loss is a common occurrence in the elderly. Unintentional weight loss that is associated with an increased risk of morbidity and mortality is generally defined as a weight loss of 5% body weight over a period of 6-12 months.[23,26] Among individuals with unintentional weight loss, a minority are diagnosed with malignancy.[24,25] There is no unified published consensus or guideline to guide the workup for weight loss, but most publications recommend that the primary workup should be symptom-focused and include laboratory studies and age-appropriate cancer screening. Workup for particular symptoms or lab findings should be guided by condition-specific guidelines. Based on symptoms and lab findings, thyroid ultrasound, abdominal/renal ultrasounds, and/or echocardiogram are medically necessary. All individuals with CNS symptoms or abnormal pituitary hormones warrant an MRI. A chest x-ray is reasonable in all individuals.[23,26,27]

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

A negative baseline evaluation is reassuring, with at least one prospective study showing that no individuals with a negative baseline clinical and laboratory evaluation were found to have malignancy on subsequent studies.[23,27] However, other prospective studies do illustrate that underlying malignancy may be detected on advanced imaging, with the highest predictive value for lung, pancreatic, lymphomas, prostate and colorectal cancers.[24,25] Based on this, these guidelines support contrasted CT Chest as part of initial workup for all smokers with clinically significant weight loss. These guidelines also support CT or MRI Abdomen (or CT Abdomen and Pelvis) as part of initial workup for individuals age 60+ with clinically significant weight loss and additional signs and symptoms significantly associated with pancreatic cancer.[13] For all other individuals, if the individuals have clinically significant unintentional weight loss as defined in paragraph 1, and the initial baseline evaluations above are negative, CT with contrast of the chest, abdomen, and pelvis are medically necessary.[23,24,26]

No published algorithm routinely supports PET/CT in the evaluation of unexplained weight loss, and there are no prospective studies illustrating the sensitivity or specificity of PET in this scenario. There may be individuals who meet evidence-based criteria for PET/CT based on their specific signs, symptoms and findings, particularly in the lymphomas (refer to guidelines **ONC-27**, **ONC-28**, and **ONC-1.4)**.

Paraneoplastic Syndromes (ONC-30.3)

ON.MC.0030.3.A
v3.0.2026

- Paraneoplastic syndromes are metabolic and neuromuscular disturbances. These syndromes are not directly related to a tumor or to metastatic disease. There may be a lead time between initial finding of a possible paraneoplastic syndrome and appearance of the cancer with imaging. Limited studies suggest annual imaging for 2 years after diagnosis of possible paraneoplastic syndrome may detect cancer; however, the benefit after 2 years is not well documented.
- The following are the most common symptoms of paraneoplastic syndromes known to arise from various malignancies:
  - Hypertrophic Pulmonary Osteoarthropathy: Often presents as a constellation of rheumatoid-like polyarthritis, periostitis of long bones, and clubbing of fingers and toes
  - Amyloidosis
  - Hypercalcemia
  - Hypophosphatemia
  - Cushing's Syndrome
  - Somatostatinoma syndrome (vomiting, abdominal pain, diarrhea, cholelithiasis)
  - Syndrome of inappropriate antidiuretic hormone secretion (SIADH)
  - Polymyositis/dermatomyositis
  - Opsoclonus
  - Paraneoplastic sensory neuropathy
  - Subacute cerebellar degeneration
  - Eaton-Lambert syndrome (a myasthenia-like syndrome)
  - Second event of unprovoked thrombosis
  - Disseminated Intravascular Coagulation
  - Migratory thrombophlebitis
  - Polycythemia
  - Chronic leukocytosis and/or thrombocytosis
  - Elevated tumor markers (including but not limited to: CEA, CA 19-9, CA 27-9, CA 15-3, CA 125, inhibin A and B, AFP, unexplained HCG)
  - Cryptogenic stroke (see also: **HD-21.3)**
- See: **Muscle Disorders (PN-6)** in the Peripheral Nerve Disorders Imaging Guidelines.
- See: **Multiple Myeloma and Plasmacytomas (ONC-25)** for evaluation of possible multiple myeloma.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- See: **Abnormal Non-Invasive Prenatal Testing (NIPT) and Maternal Malignancy (PV-15.5)** in the Pelvis Imaging Guidelines for NIPT Paraneoplastic syndromes.

Indication	Medically Necessary Imaging Study
Initial evaluation	• CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast
ANY of the following: • Abnormality on conventional imaging difficult to biopsy • Inconclusive conventional imaging • Documented paraneoplastic antibody and conventional imaging fails to demonstrate primary site	• PET/CT (CPT® 78815 or CPT® 78816)
Subsequent evaluation for known paraneoplastic syndrome	• CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast every 6 months for 2 years after initial imaging for Lambert-Eaton Myasthenia syndrome • CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast every 6 months for 4 years for all other paraneoplastic syndromes
Systemic mastocytosis	ANY ONE of the following: • CT Abdomen and Pelvis (CPT® 74177) with contrast • MRI Abdomen (CPT® 74183) and MRI Pelvis (CPT® 72197) without and with contrast • PET/CT scan is not medically necessary for evaluation of mastocytosis
First episode of unprovoked DVT/VTE	• Imaging to evaluate for malignancy is not medically necessary
Second unprovoked DVT/PE	• Imaging may be considered in the setting of a negative work-up for inherited thrombophilia and antiphospholipid syndrome

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Thyroid US is recommended for elevated CEA	

Evidence Discussion

Cross-sectional imaging with contrasted CT of the chest, abdomen and pelvis is generally considered first-line to look for visceral malignancy in most paraneoplastic syndromes. While sensitivity varies widely (30%-82% across studies), specificity is reasonable (71%-100%).[33] PET/CT is medically necessary in individuals with documented paraneoplastic antibodies, inconclusive conventional imaging, or to assess for alternate biopsy sites when an abnormality is found on conventional imaging that is inaccessible for biopsy. The sensitivity and specificity of PET/CT is approximately 80% when used to evaluate individuals who had negative or unclear conventional imaging.[29] PET/CT is not medically necessary as first line imaging as PET may miss smaller tumors and has a false negative rate of approximately 20% in this setting .[33] While there is a lack of prospective data on monitoring paraneoplastic syndromes, it is known that these phenomena may precede detectable malignancy. In the interest of individual safety, these guidelines support repeat CT imaging every 6 months for 4 years; for Lambert-Eaton Syndrome, 2 years is sufficient as 96% of associated SCLC is detected in the first year, with later reports generally from an era of lesser quality CTs.[30,31,34]

Venous thromboembolism in the absence of a hypercoagulable risk factor may suggest occult malignancy. Blood testing, exam, and non-advanced imaging have been shown to be helpful in most cancers that present with a first unprovoked DVT, but other advanced imaging is not cost-effective without other symptoms suggesting malignancy in this setting. In the setting of a second unprovoked DVT, cross-sectional imaging with contrasted CT is medically necessary.[31,35,36]

Systemic mastocyctosis may also develop extramedullary involvement and end-organ dysfunction, particularly involving liver and spleen. CT or MRI of abdomen and pelvis are medically necessary in alignment with NCCN. There is no NCCN recommendation for PET/CT in systemic mastocytosis.

General Guidelines (ONC-31.0)

ON.UP.0031.0.A

v3.0.2026

- Guideline sections Lung Metastases (ONC-31.1) through Spinal Vertebral Metastases (ONC-31.6) are designed to supplement the disease-specific guidelines when the disease-specific guidelines do not provide guidance on the clinical scenario in question.
- These sections can also be used if the cancer type is rare and does not have its own diagnosis-specific imaging guidelines.
- These sections may also be used for lesions suspicious for cancer that do not have guidance in other disease-specific areas of the guidelines.

Proprietary Information of UnitedHealthcare.

Lung Metastases (ONC-31.1)

ON.UP.0031.1.A
v3.0.2026

Indication	Medically Necessary Imaging Study
New or worsening signs or symptoms suggestive of metastatic lung involvement or new or worsening chest x-ray abnormality	• CT Chest with contrast (CPT® 71260) • CT Chest without contrast (CPT® 71250) if there is a contraindication to CT contrast or only parenchymal lesions are being evaluated
Chest wall or brachial plexus involvement	• MRI Chest without and with contrast (CPT® 71552)
ONE of the following **and** no diagnosis-specific guideline regarding PET imaging: • Lung nodule(s) ≥8mm • Confirm solitary metastasis amenable to resection on conventional imaging	• PET/CT (CPT® 78815) • When primary cancer known, PET request should be reviewed by primary cancer guideline
Previous or current malignancy and pulmonary nodule(s) that would reasonably metastasize to the lungs	• CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) at 3, 6, 12, and 24 months from the first study • For subsolid nodules, ongoing surveillance after 24 months is medically necessary. Refer to **Incidental Pulmonary Nodules Detected on CT Images (CH-16.2)** for follow-up for subsolid nodules after the 24 month timeframe.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Suspected drug-induced or radiation-induced pulmonary toxicity	CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) for the following: • Initial evaluation • Repeat imaging at the timing of the discretion of the treating provider ◦ Worsening symptoms or PFTs ◦ Guide for steroid taper ◦ Baseline prior to re-exposure to offending agent

Evidence Discussion

All individuals with a history of cancer who have new signs or symptoms suggestive of metastatic disease to the lung, or who have new or worsening findings on chest x-ray, warrant CT Chest. Contrast is preferable in most scenarios to include evaluation of soft tissue and nodes, but a non-contrast study may be approved if there is a contraindication to contrast or if only parenchymal lung lesions are being evaluated. CT with contrast (or without if for parenchymal lesion only) is medically necessary to follow up new lung nodules in individuals with a history of malignancy.[55] There is, however, no clear consensus on a timeline for this follow up across all malignancy types. Where guidance is not provided in the disease-specific guidelines, these guidelines suggest a follow up timeline of CT at 3, 6, 12, and 24 months from discovery of nodule, extrapolating from Fleischner and Lung-RADS data that a nodule stable >24 months is exceedingly unlikely to be malignant.[54,55] MRI with and without contrast is medically necessary for suspected malignant infiltration of the brachial plexus or chest wall infiltration, for better soft tissue delineation.[52,53]

PET/CT is generally addressed in the guidelines for each specific cancer. If no specific guidance is provided, PET/CT is medically necessary for lung nodules greater than or equal to 8mm.[54] In the interest of safety to prevent futile invasive procedures on individuals with occult metastatic disease, PET/CT is also medically necessary by these guidelines to confirm solitary metastasis on conventional imaging that may be amenable to curative-intent resection. PET/CT surveillance is not generally medically necessary due to high radiation exposure, financial toxicity, and excess radiation exposure.

Liver Metastases and Liver-Directed Therapies (ONC-31.2)

ON.UP.0031.2.A

v3.0.2026

- Yitrium-90 Radioembolization (Y90-RE) is also known either as Selective Internal Radiation Therapy (SIRT) or trans-arterial radioembolization (TARE). Y90-RE is medically necessary for inoperable hepatocellular carcinoma and metastatic disease to the liver. Yitrium-90 resin or glass microsphere is injected into the hepatic vessel which supplies the tumor bed. This delivers high radiation dose to the tumor selectively.
- Yitrium-90 Radioembolization consists of three parts:

1. The pre-treatment planning angiogram with Technetium 99m macroaggregated albumin (Tc-MAA). The Tc-MAA acts as surrogate for biodistribution of application of Y-90. Planar or SPECT/CT are performed for calculation of lung shunt fraction and identification of extra hepatic uptake. The assessment of hepatopulmonary shunt is important in the determination eventual radiation dose. Presence of extra-hepatic uptake may preclude treatment or require coil embolization.
2. Yitrium-90 Radioembolization treatment is typically done 7-10 days after mapping.
3. Post-treatment imaging may be done to confirm tumor localization.

- Ablation of liver metastases or primary HCC may be performed utilizing chemical, chemotherapeutic, radiofrequency, or radioactive isotope. Regardless of the modality of ablation, PET is not medically necessary for assessing response to this mode of therapy.

Indication	Medically Necessary Imaging Study
New or worsening signs or symptoms suggestive of metastatic liver involvement or new elevation in LFTs	• CT Abdomen with (CPT® 74160) or without and with (CPT® 74170) contrast
ANY of the following: • Considering limited resection • Inconclusive CT findings • Inconclusive liver findings on PET/CT	• MRI Abdomen without and with contrast (CPT® 74183)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
ONE of the following **and** no diagnosis-specific guideline regarding PET imaging: • Confirm solitary metastasis amenable to resection on conventional imaging • LFT's and/or tumor markers continue to rise and CT and MRI are negative	• PET/CT (CPT® 78815) ◦ When primary cancer known, PET request should be reviewed by primary cancer guideline
Monitoring of liver metastases that have been surgically resected	• Review according to primary cancer guideline
Evaluation of hepatic artery chemotherapy infusion or TACE (transarterial chemoembolization)	• CTA Abdomen (CPT® 74175) immediately prior to embolization ONE of the following studies immediately prior to and one month post-embolization, if not previously done: • CT Abdomen without and with contrast (CPT® 74170) • MRI Abdomen without and with contrast (CPT® 74183)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Medically Necessary Imaging Study
Evaluation for hepatic artery radioembolization with Y-90 radioactive spheres (TheraSphere or SIR Spheres) for liver metastases or primary liver tumors	To assess hepatic vascular anatomy before the procedure, any ONE of the following: • 3D Rendering (CPT® 76377) if conventional hepatic angiogram is being performed • CTA Abdomen (CPT® 74175) ONE of the following studies PRE-treatment based upon provider preference: • Radiopharmaceutical Localization Limited Area (CPT® 78800 or CPT® 78801) • SPECT or SPECT/CT (CPT® 78803, 78831, 78830, or 78832) • CPT® 78835 may be approved as an add-on code with SPECT/CT codes only (CPT® 78803, 78831, 78830, or 78832) for calculation of lung shunt fraction if planar imaging (CPT® 78800 or CPT® 78801) not performed. Liver-lung shunt calculation is included in planar scans and does not require additional Lung Perfusion Scan ONE of the following studies POST-treatment based upon provider preference: • Radiopharmaceutical Localization Limited Area (CPT® 78800 or CPT® 78801) • SPECT or SPECT/CT (CPT® 78803, 78831, 78830, or 78832)
Monitoring of ablated liver metastases or primary tumors	ONE of the following, immediately prior to ablation, 1 month post-ablation, then every 3 months for 2 years, and then every 6 months until year 5: • CT Abdomen without and with contrast (CPT® 74170) • MRI Abdomen without and with contrast (CPT® 74183)

Evidence Discussion

For individuals with known malignancy with new symptoms suggestive of metastatic liver involvement or increase in LFTs, these guidelines support CT of the abdomen

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

with contrast or without and with contrast as first line imaging. This helps differentiate vascular enhancement patterns, number of lesions, and associated abdominal findings. If the CT remains indeterminate, MRI without and with contrast is medically necessary as MRI enables better characterization of the internal features of the lesion.[56,57] For safety, MRI is also medically necessary if limited resection is being considered.

PET/CT is less specific than conventional imaging for liver lesions, and is not first line to clarify indeterminate liver findings on CT.[56] However, if LFTs or tumor markers continue to rise and CT and MRI are negative, PET/CT may be used as a problem-solving tool to look for occult metastatic disease.[56] In the interest of safety, if a curative-intent resection of a liver lesion is planned, PET/CT may be used to confirm the liver metastasis is solitary to prevent subjecting the individual to a futile resection.

Imaging is medically necessary to evaluate for hepatic artery chemotherapy infusion or transarterial chemoembolization (TACE). Either CT or or MRI with and without contrast may be used for this purpose, per provider preference based on individual tumor characteristics, per the logic noted in paragraph 1. These guidelines for imaging for radioembolization align with international working group TheraSphere Global Dosimetry Steering Committee (DSC) recommendations.[59] Vascular mapping is medically necessary prior to radioembolization with CTA abdomen (with 3D rendering if requested), as well as a single nuclear medicine liver planar study or SPECT/SPECT-CT study, based on provider preference and individual tumor characteristics.[59] Liver-lung shunt calculations can generally be calculated from pre-treatment scans and an addition lung perfusion scan is not generally medically necessary.[59] The nuclear imaging used pre-treatment is medically necessary once post-treatment, and cross-sectional imaging with CT or MRI to evaluate response is medically necessary 1 month post treatment.[59]

Monitoring of ablated liver tumors, metastatic or primary, is with cross sectional imaging with CT or MRI Abdomen, with and without contrast, per provider preference based on individual and tumor characteristics. In alignment with NCCN hepatocellular carcinoma surveillance recommendations, this guideline supports this imaging 1 month post ablation, every 3 months for 2 years, then every 6 months until year 5.[58] PET is not routinely medically necessary for follow up for ablated liver lesions, regardless of ablation modality.[58,60] The sensitivity of PET is only 65% in this setting, compared with 96% for MRI, and the positive and negative predictive values are also significantly superior for MRI vs PET.[60]

Brain Metastases (ONC-31.3)

ON.UP.0031.3.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Individual with cancer and signs or symptoms of CNS disease or known brain metastasis with new signs or symptoms.	• MRI Brain without and with contrast (CPT® 70553)
To determine candidacy for SRS, and a diagnostic thin-slice MRI Brain has not been performed in the preceding 30 days	• MRI Brain without and with contrast (CPT® 70553)
Stereotactic radiosurgery planning	• Unlisted MRI for treatment planning purposes (CPT® 76498)
Monitoring of brain metastases treated with surgery or radiation therapy	Post-treatment, then every 3 months for 1 year and every 4 months thereafter: • MRI Brain without and with contrast (CPT® 70553) ***Individuals treated with stereotactic radiosurgery alone may have MRI Brain without and with contrast (CPT® 70553) immediately after stereotactic radiosurgery, then every 2 months for the first year, and then every 6 months thereafter
Brain metastases treated with radiation therapy, with recent MRI Brain indeterminate in distinguishing radiation necrosis vs. tumor progression	• MRI Perfusion imaging (CPT® 70553)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Brain metastases treated with radiation therapy, with recent MRI Brain and MR Perfusion studies both unable to distinguish radiation necrosis vs. tumor progression	• PET Metabolic Brain (CPT® 78608)
Any of the following: • Solitary brain metastasis suspected in individual with prior diagnosis of cancer • Brain metastases and no known primary tumor	• CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast • Mammography for individuals assigned female at birth • PET/CT (CPT® 78815 or CPT® 78816) for ANY of the following: ◦ Inconclusive conventional imaging ◦ Confirm either stable systemic disease or absence of other metastatic disease ◦ When primary cancer known, PET request should be reviewed by primary cancer guideline unless there is no diagnosis-specific guideline regarding PET imaging
Primary brain tumors	See: **Primary Central Nervous System Tumors (ONC-2)**
MR Spectroscopy (CPT® 76390) is not medically necessary for evaluation of metastatic brain cancer	

Evidence Discussion

Brain metastases are the most common malignant intracranial tumors with an incidence 10-fold higher than primary central brain tumors. Common presenting signs and symptoms of brain metastases include headache, nausea, vomiting, focal neurologic deficits, and mental status changes. The most common cancer associated with brain metastases is lung cancer approaching 50% of the cases. Melanoma is associated with the highest incidence of brain metastases.

These guidelines support MRI Brain without and with contrast as the standard imaging modality for evaluation of an individual with suspected or known brain metastases. The post-treatment monitoring after surgery or radiation is based on NCCN guidelines. Specifically for stereotactic radiosurgery planning, a diagnostic MRI is not medically necessary and the MRI request is based on an unlisted procedure code. Advanced

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

imaging with MR perfusion imaging is a problem-solving tool, complementing a standard MRI Brain, to distinguish between radiation necrosis and tumor progression. PET Metabolic Brain imaging is a useful tool to distinguish between radiation necrosis and tumor progression with recent indeterminate MRI Brain and MR Perfusion study.

In individuals who present with brain metastases and no known primary tumor, an evaluation to define a primary cancer is medically necessary. Imaging studies that are medically necessary include CT Chest and CT Abdomen and Pelvis with contrast. Mammography is medically necessary for this staging in individuals assigned female at birth. PET/CT is medically necessary for inconclusive standard imaging, for evaluation of other metastatic disease or for staging if supported by primary cancer guideline. Biopsy or resection of a suspicious lesion is needed to establish a definitive diagnosis.

Adrenal Gland Metastases (ONC-31.4)

ON.UP.0031.4.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Differentiate benign adrenal adenoma from metastatic disease	• See: **Adrenal Cortical Lesions (AB-16.1)** in the Abdomen Imaging Guidelines
Known cancer and no known systemic metastases: • New adrenal mass • Enlarging adrenal mass • Inconclusive findings on recent CT	If not done previously, ANY of the following: • CT Abdomen without contrast (CPT® 74150) • CT Abdomen without and with contrast (CPT® 74170, adrenal protocol) • MRI Abdomen without contrast (CPT® 74181) • MRI Abdomen without and with contrast (CPT® 74183) • CT-directed needle biopsy (CPT® 77012)
One of the following and no diagnosis-specific guideline regarding PET imaging: • Biopsy is not feasible or is non-diagnostic • Isolated metastasis on conventional imaging and individual is a candidate for aggressive surgical management	• PET/CT (CPT® 78815) When primary cancer known, PET request should be reviewed by primary cancer guideline
Known extra-adrenal malignancy and undiagnosed adrenal mass being monitored off treatment	See: **General Guidelines (ONC-1.0)**

Evidence Discussion

In individuals with known extra-adrenal malignancy and no known systemic metastatic disease who have been found to have a new, enlarging or inconclusive adrenal mass on other imaging, a non-contrast CT adrenal protocol or CT Abdomen with and without

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

contrast adrenal protocol or an MRI Abdomen without or without and with contrast are all supported by ACR appropriateness criteria.[62] Non-contrast images allow for initial attenuation measurements, but contrast-enhanced images with imaging for washout characteristics can help differentiate adenomas from metastatic disease.[7,62] Non-contrast chemical shift MRI can help detect intracytoplasmic fat, providing insight into benign vs malignant characteristics, but post-contrast imaging adds further specificity for adenoma.[7,62] CT-directed needle biopsy may also be appropriate and is supported by the guidelines if requested.[7,62]

The utility of PET/CT varies with histology and type of radiotracer. Generally, the use of PET/CT for a given malignancy is addressed in the disease-specific guidelines. For lesions with no known history of malignancy, there is no primary evidence supporting the use of FDG PET-CT for initial evaluation.[62] In one study of 1,049 incidental adrenal masses in individuals with no known history of cancer, zero were malignant.[27] Mild SUV uptake can also be seen in benign adenomas, bringing the sensitivity of PET/CT to only 85% .[28,29,62] False-positive interpretations potentially result in unnecessary invasive procedures. When other adrenal-specific cross sectional imaging is suspicious for malignancy by size and other criteria, biopsy is preferred. If a biopsy is not feasible or non-diagnostic, PET/CT may show increased SUV uptake in malignant lesions and guide further decision making, and is supported by the ACR in this context.[7,62]

Bone (Non-Vertebral) Metastases (ONC-31.5)

ON.UP.0031.5.A
v3.0.2026

- This guideline may be used for individuals with or without a history of malignancy, depending on the indications as listed below.

Indication	Medically Necessary Imaging Study
Individuals ≥40 years of age with no history of malignancy who have a symptomatic bone lesion seen on x-ray and malignancy is suspected	EITHER of the following: • CT Chest with contrast (CPT® 71260), CT Abdomen and Pelvis with contrast (CPT® 74177), and Bone scan (CPT® 78306) OR • FDG PET/CT (CPT® 78815 or CPT® 78816)
Individuals <40 years of age with a bone lesion on x-ray	See: **Lesion of Bone (MS-10.2)**
Suspected bone metastasis due to ANY of the following in an individual with a current or prior malignancy: • Bone pain • Rising tumor markers • Elevated alkaline phosphatase	• Bone scan (CPT® 78306) supplemented by plain x-rays (see: **Nuclear Medicine (NM) Imaging in Oncology [ONC-1.3]** for additional bone scan codes)
ANY of the following: • Bone scan is not feasible or readily available • Bone scan is equivocal or indeterminate • Continued suspicion despite negative/inconclusive bone scan or other imaging modalities • Soft tissue component suspected on other imaging modalities • Differentiate neoplastic disease from Paget's disease of the bone	EITHER of the following: • MRI without and with contrast of the involved body site • CT without or with contrast of the involved body site

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Bone metastases suspected and **both** bone scan and either CT or MRI are inconclusive	• ^{18}F-FDG-PET/CT (CPT® 78815 or CPT® 78816)
EITHER of the following: • No prior cancer history with suspected bone metastatic disease or pathologic fracture on plain x-ray • Adult individuals with a biopsy-proven carcinoma of unknown origin in a bone lesion	• See: **Carcinoma of Unknown Primary Site (ONC-31.7)**

Evidence Discussion

Bone scan supplemented by plain x-ray is the generally the first-line modality for individuals with current or history of malignancy who have new bone pain, rising tumor markers or elevated alkaline phosphatase. Bone scan is 79%-86% sensitive and 81%-88% specific for metastatic lesions.[41,44] Bone scan allows rapid whole-skeletal evaluation to ensure additional bony disease is not missed by focusing on a single site of cross-sectional imaging. MRI is a useful problem-solving tool if there is continued suspicion for bony metastatic disease with a negative bone scan.[41,43] MRI is medically necessary when a soft tissue component is suspect to avoid understaging and undertreatment.[43] MRI is also the most specific study to supplement plain x-ray to differentiate Paget disease of bone from neoplastic disease.[45]

MRI is more accurate than CT or bone scan for the evaluation of malignant vertebral compression fractures and additionally can assess for cord compression, edema or leptomeningeal disease.[44] Individuals with known stage IV cancer with new back pain or any sings of neurologic compromise may be immediately evaluated by MRI of the whole spine without or without and with contrast.[44] MRI is also medically necessary for suspected leptomeningeal disease.[44] CT has the lower accuracy than MRI or bone scan in this setting and is only medically necessary when MRI is contraindicated.[44] New leptomeningeal disease should prompt an MRI of the brain for complete neuroaxis imaging.

Where imaging is suspicious for bony metastatic disease and a workup for multiple myeloma is negative, CT Chest, Abdomen, and Pelvis with contrast are medically necessary to look for a primary malignancy.[33]

The sensitivity and specificity of FDG PET-CT for bony metastatic disease varies with the malignancy. For example, for breast cancer, PET may be more sensitive (96% vs

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

76% for bone scan) but may be less specific (92% vs 95% for bone scan). However, for some cancers, sensitivity of PET is as low as 56%.[42,44] Given this variability, PET/CT is medically necessary as a problem-solving tool when both bone scan and MRI or CT are inconclusive. NCCN does support the use of FDG PET/CT specifically in individuals who 40 years of age or older and who have a symptomatic bone lesion with an abnormal x-ray.[63] These guidelines allow the flexibility of using FDG PET/CT in this specific scenario if it is desired in lieu of diagnostic CT and bone scan. NaF PET is considered investigational due to varying sensitivity and specificity.[46,47]

Spinal/Vertebral Metastases (ONC-31.6)

ON.UP.0031.6.A
v3.0.2026

- Individuals with stage IV cancer with new onset back pain can forgo a bone scan (and plain films) in lieu of an MRI with and without contrast of the spine.

Indication	Medically Necessary Imaging Study
Known cancer history and spinal cord compression suspected based on signs/ symptoms of neurological compromise, including, but not limited to: • Unexpected, sudden loss of bowel or bladder control • Sudden loss of ability to ambulate • Complete loss of pinprick sensation corresponding to a specific vertebral level • Loss of pain at a site that had previously been refractory to pain management	MRI Cervical (CPT® 72156), MRI Thoracic (CPT® 72157), and MRI Lumbar Spine (CPT® 72158) without and with contrast OR without contrast (CPT® 72141, CPT® 72146, or CPT® 72148) • CT Cervical (CPT® 72126), CT Thoracic (CPT® 72129), and CT Lumbar (CPT® 72132) Spine if MRI is contraindicated
Individual with a known history of cancer and ANY of the following: • Metastatic or stage IV cancer with new or worsening back pain • Continued suspicion despite negative/ inconclusive bone scan or other imaging modalities • Back pain and suspicion of spinal malignancy based on any one of the following: ◦ Night pain ◦ Age >70 years ◦ Uncontrolled or unintentional weight loss ◦ Pain unrelieved by change in position ◦ Severe or worsening spinal pain	ONE of the following: • MRI of the relevant spinal level without contrast • MRI of the relevant spinal level without and with contrast • CT of the relevant spinal level without contrast • CT Myelogram of the relevant spinal level

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Monitoring untreated vertebral metastases	One of the following, every 3 months for 1 year: • MRI without and with contrast of the involved spinal level • CT without or with contrast of the involved spinal level **Imaging beyond 1 year is based on any new clinical signs/symptoms
Monitoring metastases within the spine treated with surgery and/or radiation therapy	One of the following, once within 3 months post-treatment, and then every 3 months for 1 year: • MRI without and with contrast of the involved spinal level • CT without or with contrast of the involved spinal level **Imaging beyond 1 year is based on any new clinical signs/symptoms

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Leptomeningeal involvement with cancer	Suspected: • MRI Brain without and with contrast (CPT® 70553) and MRI Cervical (CPT® 72156), Thoracic (CPT® 72157), and Lumbar spine (CPT® 72158) without and with contrast • CT Cervical (CPT® 72127), Thoracic (CPT® 72130), and Lumbar Spine (CPT® 72133) without and with contrast is medically necessary if MRI is contraindicated or not readily available On active treatment: • MRI Brain without and with contrast (CPT® 70553) and MRI Cervical (CPT® 72156), Thoracic (CPT® 72157), and Lumbar spine (CPT® 72158) without and with contrast every 2 cycles • CT without or with contrast of the involved spinal level if MRI is contraindicated Once treatment completed: • Routine advanced imaging not medically necessary for surveillance in asymptomatic individuals

Evidence Discussion

The incidence of malignant cord compression varies with cancer type but is rarely the first sign of systemic cancer. Back pain is the most common presenting symptoms and is reported in 80%-95% of individuals. Pain is often refractory to traditional pain medications. Sensory and motor deficits occur in 35%-75% of individuals, and acute bowel/bladder dysfunction are other red flags for cord compression. Up to 35% of individuals have multiple levels of compression, which may be non-contiguous, and as such where symptoms as above suggest cord compression in an individual with a history of malignancy, imaging of the whole spine is medically necessary. MRI with and without contrast has a sensitivity and specificity of 93% and 97%, respectively. ACR Appropriateness Criteria® stated CT Myelogram 'may be appropriate' in this setting, may be faster to obtain, and may be necessary to plan surgical intervention; thus, it is also supported by these guidelines for suspected malignant cord compression.[24,25,26]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Some individuals will present with more localized symptoms suggestive of localized nerve root involvement but not consistent with the above symptoms of cord compression. Unilateral symptoms suggest a lower motor neuron lesion. Other symptoms suggestive of nerve root involvement are night pain, refractory pain, and pain unrelieved by a change in position. Elderly individuals with a cancer history are also at higher risk for nerve root involvement. Unintentional weight loss without other localizing symptoms may also suggest nerve root involvement. In individuals with a history of malignancy with any of the above, MRI without and with contrast of the involved spinal level of symptoms is medically necessary. CT is less sensitive than MRI in this setting and is medically necessary only when MRI is contraindicated.[24,25,26]

Carcinoma of Unknown Primary Site (ONC-31.7)

ON.UP.0031.7.A
v3.0.2026

General Considerations

- Defined as carcinoma found in a lymph node or in an organ known not to be the primary for that cell type (e.g., adenocarcinoma arising in the brain or in a neck lymph node).
- This guideline also applies to a pathologic fracture that is clearly due to metastatic neoplastic disease in an individual without a previous cancer history.
- Detailed history and physical examination including pelvic and rectal exams and laboratory tests to be performed before advanced imaging.
- Individuals presenting with a thoracic squamous cell carcinoma described as metastatic appearing on chest imaging, or in lymph nodes above the clavicle, should undergo a detailed head and neck examination by a clinician skilled in laryngeal and pharyngeal examinations, especially in smokers.
- Individuals with suspected unknown primary based on only suspicious lytic bone lesions should be considered for serum protein electrophoresis (SPEP), urine protein electrophoresis (UPEP), and serum free light chains prior to consideration of extensive imaging.

Indication	Medically Necessary Imaging Study
Carcinoma found in a lymph node or in an organ known not to be primary	• CT Chest (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Neck with contrast (CPT® 70491) if cervical or supraclavicular involvement • CT with contrast or MRI without and with contrast of any other symptomatic site • For individuals assigned female at birth: ◦ Diagnostic (not screening) mammogram and full pelvic exam ◦ MRI Breasts Bilateral (CPT® 77049) if pathology consistent with breast primary and mammogram is inconclusive

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Sebaceous carcinoma of the skin (can be associated with underlying primary malignancy)	• CT Chest (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) • CT Neck with contrast (CPT® 70491) if cervical or supraclavicular involvement • CT with contrast or MRI without and with contrast of any other symptomatic site
Axillary adenocarcinoma	• Diagnostic (not screening) mammogram and full pelvic exam • MRI Breasts Bilateral (CPT® 77049) if pathology consistent with breast primary and mammogram is inconclusive • If the above are non-diagnostic for primary site: ◦ CT Neck (CPT® 70491), CT Chest (CPT® 71260), and CT Abdomen (CPT® 74160) with contrast ◦ CT with contrast or MRI without and with contrast of any other symptomatic site
EITHER of the following: • Carcinoma found within a bone lesion • Unexplained pathologic fracture	• CT Chest (CPT® 71260) and CT Abdomen and Pelvis with contrast (CPT® 74177) • Bone Scan (CPT® 78306) (see: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes) • CT with contrast or MRI without and with contrast of any symptomatic site
ANY of the following: • Above studies have failed to demonstrate site of primary • CT scans reveal isolated metastatic disease for which definitive curative therapy is planned	• PET/CT (CPT® 78815 or CPT® 78816)
Post-treatment surveillance	• Follow-up with CT Chest (CPT® 71260), CT Abdomen and Pelvis (CPT® 74177), and CT of any other involved areas every 6-12 months for 5 years

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion

Carcinoma of unknown primary site (CUP) is defined as carcinoma found in a lymph node or in an organ known not to be the primary for that cell type (e.g., adenocarcinoma arising in the brain or in a neck lymph node). This guideline also applies to a pathologic fracture that is clearly due to metastatic neoplastic disease in an individual without a previous cancer history. Individuals with suspected unknown primary based on only suspicious lytic bone lesions should be considered for serum protein electrophoresis (SPEP), urine protein electrophoresis (UPEP), and serum free light chains prior to consideration of extensive imaging.

CUP generally occurs in older adults, the majority 6-75 years, and accounts for 2-9% of all tumors. Median survival is poor, at 3-10 months. Twenty percent of individuals fall into a more favorable risk group with median survival >1 year, and imaging may help identify this group.[1,30] The primary step in workup of CUP, before advanced imaging, is a detailed history and physical examination including pelvic and rectal exams and laboratory tests, including basic CBC/Chemistries/LFTs but also tumor markers, immunohistochemistry, and PSA (for individuals assigned male at birth over 40). Endoscopy should also be considered if pathology suggests a GI primary. CT of the chest, abdomen, and pelvis with contrast is medically necessary for all individuals where primary site is not suggested on physical and lab evaluation, in alignment with NCCN and the European Society of Medical Oncology (ESMO).[1,30] CT Neck may be included if cervical or supraclavicular involvement, as well as CT or MRI for other symptomatic sites or abnormal sites on physical, with the choice of modality driven by body site of interest. If the site of carcinoma is a bone lesion that is not consistent with multiple myeloma, a bone scan should be added to the workup. Morphology on bone scan can help determine the primary site, where lytic lesions are most suggestive of myeloma, renal cell, GI and melanoma, and blastic lesions most commonly occur with prostate cancer and GI carcinoid. Other morphologic features such as location and expansile nature can also help guide workup and treatment toward a particular primary site.[33] PET/CT has not been shown to be superior to bone scan for this purpose, and in fact may be less sensitive than bone scan for lesions <1cm.[1,33]

It is essential that individuals assigned female at birth have a diagnostic (not screening) mammogram and full pelvic exam. If pathology is consistent with breast cancer from axillary node or other metastatic site, but mammogram is inconclusive, a bilateral breast MRI with and without contrast is medically necessary, as MRI may identify the breast as the primary site in approximately half of the individuals presenting with axillary adenocarcinoma metastases.[1,32] If a primary site is still not found, CT Neck, Chest, Abdomen, and Pelvis are medically necessary.

These guidelines align with NCCN and support PET/CT as a problem-solving tool to look for a primary site of disease when the studies described above still do not reveal a primary site.[1] PET is of intermediate specificity in this setting and large randomized trials

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

are lacking.[1] A meta-analysis on the use of PET/CT in individuals with CUP found that primary tumors were detected in 37% of 433 individuals across 11 studies, with pooled sensitivity and specificity of 84%.[1,31] In addition, if CT scans reveal oligometastatic disease and definitive curative therapy is planned, the absence of other sites of disease may be confirmed with PET/CT to prevent over- or under-treatment.[1,30]

Subsequent imaging and surveillance should follow the guideline for each primary site, once a likely primary has been established. NCCN stated follow-up should be with history and physical with subsequent diagnostic testing based on symptoms. In 20%-50% of individuals, the primary site remains unidentified even after postmortem examination; thus, continued imaging is low-yield and may contribute to the significant distress associated with the uncertainty of this condition.[1,30] There is no data-driven algorithm for imaging surveillance when the primary site of disease remains undiscovered.[1]

Extrathoracic Small Cell and Large Cell Neuroendocrine Tumors (ONC-31.8)

ON.UP.0031.8.A

v3.0.2026

- All poorly-differentiated or high-grade, small cell and large cell neuroendocrine tumors arising outside the lungs or of unknown primary origin are imaged according to these guidelines.
- For intrathoracic poorly differentiated neuroendocrine cancer, see: **Small Cell Lung Cancer (ONC-7)**

Indication	Medically Necessary Imaging Study
Initial staging	ONE of the following combinations: • CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast • CT Chest with contrast (CPT® 71260) and MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)
Inconclusive findings on conventional imaging studies	• PET/CT (CPT® 78815)
ANY of the following: • Poorly differentiated neuroendocrine cancers of the head or neck • Signs or symptoms of CNS involvement	• MRI Brain without and with contrast (CPT® 70553)
Restaging during treatment	ONE of the following combinations, every 2 cycles: • CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) and CT of any known sites of disease with contrast • CT Chest with contrast (CPT® 71260) and MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) and CT with contrast of any known sites of disease

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Medically Necessary Imaging Study
Suspected Recurrence	ANY or ALL of the following are medically necessary: • CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast or CT Chest with contrast (CPT® 71260) and MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) • MRI Brain without and with contrast (CPT® 70553) • Bone scan (CPT® 78306) (See: **Nuclear Medicine (NM) Imaging in Oncology (ONC-1.3)** for additional bone scan codes) • PET imaging is generally **not** medically necessary but can be considered for rare circumstances.
Surveillance	ONE of the following combinations every 3 months for 1 year, then every 6 months: • CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) • CT Chest with contrast (CPT® 71260) and MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197)

Evidence Discussion

Poorly differentiated/high-grade neuroendocrine tumors (NET) may occur anywhere in the body and exhibit more aggressive behavior than other neuroendocrine tumors. When these tumors occur in the lung, they are managed like small cell lung cancer and the small-cell lung cancer guidelines apply. This section refers to extrathoracic, poorly-differentiated or high-grade NETs.

Initial Staging

Initial staging with contrasted CT of the chest, abdomen and pelvis is medically necessary, with sensitivity and specificity ranging from 82%-100% .[9,51] Metastatic disease, particularly to the liver, is common with this entity within this setting .[48,49] MRI is equally supported by NCCN for imaging of the abdomen and pelvis. Given the undifferentiated nature of these tumors, dotatate PET/CT is not routinely medically necessary as they do not consistently have somatostatin receptors, with some studies showing this modality missing 50% of tumors.[49] Sensitivity and specificity of FDG-PET/CT is superior to somatostatin-receptor based imaging for undifferentiated tumors, but is still widely variable and is not medically necessary for first line imaging but may be used as a problem-solving tool when conventional imaging is inconclusive.[9,50] Poorly

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

differentiated NETs do have a propensity for CNS involvement, and MRI Brain with and without contrast is medically necessary for initial staging with head and neck primary site or for any signs and symptoms suggestive of CNS involvement .[9,49] Suspected bony metastatic disease may be evaluated using guideline **ONC-31.5**.

Restaging and Suspected Recurrence

In alignment with NCCN, conventional imaging may be repeated every 2 cycles of treatment. In the case of suspected recurrence, CT Chest, Abdomen, and Pelvis with contrast are medically necessary as well as MRI Brain and Bone scan, in alignment with NCCN.[9] FDG PET/CT is not routinely medically necessary in this setting for the reasons cited in the section on initial staging but may be utilized in rare circumstances in the interest of safety.

Surveillance

Guidelines support conventional imaging studies every 3 months for the first year, then every 6 months for 4 additional years, then annually indefinitely due to the long term-risk of recurrence in this entity.[9,48]

Primary Peritoneal Mesothelioma (ONC-31.9)

ON.UP.0031.9.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Initial staging	• CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast • PET/CT (CPT® 78815) if there is no evidence of metastatic disease or conventional imaging is inconclusive
Recurrence/ Restaging	• If there is known prior disease, CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast • PET for inconclusive finding on conventional imaging
Surveillance	• CT Abdomen and Pelvis with contrast (CPT® 74177) every 3-6 months for 5 years, then annually until year 10

Evidence Discussion

Contrasted CT of chest, abdomen and pelvis is essential to assess the degree of dissemination, verify that peritoneal disease is not metastatic from another primary site, evaluate lymphadenopathy, and to identify metastatic disease. For primary peritoneal mesothelioma, most individuals present with advanced locoregional disease.[35] Spread into pleural space and local lymph nodes are the primary sites of metastatic disease, with more distant/diffuse metastatic disease much less common.[35,36] Sensitivity of CT is superior to MRI for this entity. As with other malignancies, if CT shows a liver lesion indeterminate for metastatic disease, MRI may be used for further assessment per guideline section ONC-31.2. The sensitivity of PET-CT for malignant peritoneal mesothelioma ranges from 58%-100%, so it is not a primary imaging tool for staging. However, PET/CT may detect small peritoneal implants that are missed on CT and alter management.[34] PET/CT is medically necessary when no metastatic disease is detected on conventional imaging to ensure individuals are not under-staged.

Contrasted CT of the abdomen and pelvis are medically necessary for restaging, as sensitivity of CT is superior to MRI for this disease process. Given that progression to chest disease is rare, CT Chest is medically necessary for restaging only if there is known disease in the chest or if new chest symptoms develop. Given the widely variable sensitivity of PET/CT for peritoneal mesothelioma, it is medically necessary only for inconclusive findings on conventional imaging.[35]

Click Here to Return to the Main TOC

NCCN guidelines and outcome data supported contrasted CT of the Chest/Abdomen/ Pelvis every 3 months for 2 years then annually until year 10.[34,35] Frequent imaging is medically necessary only within the first two years as 68% of recurrences occur within the first 2 years, then annual imaging moving forward.[35]

Kaposi's Sarcoma (ONC-31.10)

ON.UP.0031.10.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Kaposi's Sarcoma	• Advanced imaging is not medically necessary since disease is generally localized to skin. • CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast at initial diagnosis. If initial scans are negative then future imaging would be based on signs or symptoms.

Evidence Discussion

Most Kaposi Sarcoma (KS) is most often confined to skin; however, it can sometimes be found in viscera, particularly in HIV-associated disease. To prevent under-staging and to assess the need for systemic therapy, CT of the Chest, Abdomen, and Pelvis with contrast are medically necessary at initial diagnosis.[61]

Routine advanced imaging is not medically necessary if there is no visceral disease at diagnosis, but restaging CTs may be approved for individuals with visceral disease on systemic therapy per the timeframes offered in ONC-1.2. Contrasted CTs may also be approved to evaluate areas with specific signs and symptoms of new involvement.[61]

There are no data or expert consensus that support routine surveillance imaging for Kaposi's Sarcoma.[61]

Castleman's Disease (Unicentric and Multicentric) (ONC-31.11)

ON.UP.0031.11.A
v3.0.2026

Indication	Medically Necessary Imaging Study
Initial staging	• Either CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast **or** PET/CT (CPT® 78815) • CT Neck with contrast (CPT® 70491) if cervical or supraclavicular involvement • If CT scans were utilized initially and suggested unicentric disease, and surgical resection is being considered, PET/CT (CPT® 78815) can be approved to confirm unicentric disease • If unicentric disease is surgically removed, proceed to surveillance section
Restaging: • Multicentric disease or surgically unresected unicentric disease on chemotherapy	ONE of the following every 2 cycles: • CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast • PET/CT (CPT® 78815)
ANY of the following: • Suspected recurrence • Recurrent B symptoms • Rising LDH/IL-6/ VEGF levels	ONE of the following: • CT Chest (CPT® 71260) and CT Abdomen and Pelvis (CPT® 74177) with contrast • PET/CT (CPT® 78815)
Surveillance	• CT with contrast of involved areas no more than every 6 months up to 5 years

Evidence Discussion

Initial Staging

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

PET/CT fusion is medically necessary for initial staging of Castleman's Disease.[37] PET/CT not only assesses for multicentric disease, but the SUV can be used to determine Castleman's disease vs frank lymphoma.[39] Diagnostic, contrasted CTs of the chest, abdomen, pelvis, as well as neck (if suspected neck disease) may be substituted for PET/CT, but diagnostic CT is not generally medically necessary concurrently with PET.[37] However, if diagnostic CTs were utilized initially and surgical resection is being considered, these guidelines allow a PET/CT to be done subsequently in the interest of safety, to confirm unicentric disease and prevent under-staging.

Restaging/Recurrence

Unicentric disease that is surgically resected is considered to be in surveillance and imaging follows surveillance guidelines. For multicentric disease (MCD) or unresected unicentric disease on chemotherapy, disease may be monitored every 2 cycles with contrasted CT of the chest, abdomen and pelvis or PET/CT fusion studies, in alignment with NCCN. The same imaging is medically necessary for suspected recurrence or labs concerning for development of POEMS-associated MCD or HHV-8 MCD, as these entities are rapidly aggressive[38,39] Concurrent contrasted diagnostic CTs with PET/CT fusion studies do not generally change management and as such are not medically necessary, nor are concurrent scans suggested by NCCN or international consensus recommendations.[37-40]

Surveillance

There are no clear consensus guidelines for imaging surveillance of Castleman's Disease. In the interest of safety, given a multitude of curative treatment options for recurrent disease, these guidelines support surveillance imaging with CT with contrast of involved body areas no more than every 6 months up to 5 years. PET/CT is not medically necessary for surveillance in alignment with ASCO Choosing Wisely campaign.

General Guidelines (PV-1.0)

PV.GG.0001.0.U

v2.0.2026

- A current clinical evaluation since the onset or change in symptoms is required before advanced imaging can be considered. The clinical evaluation should include a relevant history and physical examination including a pelvic and/or urological exam, appropriate laboratory studies, and non-advanced imaging modalities such as plain x-ray or Pelvic ultrasound (CPT® 76856 or CPT® 76857) and/or Transvaginal ultrasound (CPT® 76830) and/or Transperineal ultrasound (CPT® 76872).
  - Other meaningful contact (telehealth visit, telephone call, electronic mail or messaging) since the onset or change in symptoms for follow up visit by an established individual can substitute for a face-to-face clinical evaluation.
- The use of gynecology CPT codes for pregnant females is not supported. Therefore, transvaginal ultrasound (CPT® 76830) and pelvic ultrasound (CPT® 76856 or CPT® 76857) are not medically necessary for those with a positive pregnancy test or known pregnancy. If a pregnancy test is positive, then obstetrical CPT codes are medically necessary.
- Abdominal imaging begins at the diaphragm and extends to the umbilicus or iliac crest.
- Pelvic imaging begins at the iliac crest and extends to the pubis.
- The uterus, tubes and ovaries arise out of the pelvis and are considered pelvic organs. If the uterus or adnexa rise out of the pelvic cavity, above the level of the iliac crest or umbilicus on physical exam or on previous imaging, abdominal imaging may be added for the completion of imaging.
- MRI (MRI Pelvis without contrast CPT® 72195) for Defecography is considered investigational/experimental by UHC.

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

General Guidelines – Overview (PV-1.1)

PV.GG.0001.1.A
v2.0.2026

- When medically necessary, pregnant females should be evaluated with ultrasound or MRI without contrast to avoid radiation exposure. In carefully selected clinical circumstances, evaluation with CT may be medically necessary with careful attention to technique and radiation protection as deemed clinically appropriate.

Ultrasound

- Transvaginal ultrasound is the standard modality for imaging; no alternative modality has demonstrated sufficient superiority to justify routine use, and Transvaginal (TV) ultrasound (CPT® 76830) is the optimal study to evaluate adult female pelvic organ pathology.
- Pelvic ultrasound (complete CPT® 76856, or limited CPT® 76857) is medically necessary if it is a complementary study to the TV ultrasound. It may substitute for TV in pediatric individuals or non-sexually active females assigned at birth.
- Transperineal ultrasound (CPT® 76872) is medically necessary for cases of suspected urethral abnormalities, urinary incontinence, pelvic prolapse, or vaginal cysts.
- CPT® 76942 is used to report ultrasound imaging guidance for needle placement during biopsy, aspiration, and other percutaneous procedures.

Soft Tissue Ultrasound

- Pelvic wall, buttocks, and penis - CPT® 76857

Scrotal Ultrasound

- See
  - **Impotence/Erectile Dysfunction (PV-17.1)**
  - **Penis-Soft Tissue Mass (PV-18.1)**
- Ultrasound scrotum and contents - CPT 76870

3D Rendering with Ultrasound

- 3D Rendering (CPT® 76376 or CPT® 76377)
  - CPT® 76377 (3D rendering requiring image post-processing on an independent work station) or CPT®

    76376 (3D rendering not requiring image post-processing on an independent workstation) in the following clinical scenarios is medically necessary:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - Uterine intra-cavitary lesion when initial ultrasound is equivocal (See **Abnormal Uterine Bleeding (AUB) (PV-3.1)** and **Leiomyoma/Uterine Fibroids (PV-12.1)**
  - Hydrosalpinges or peritoneal cysts when initial ultrasound is equivocal (See **Complex Adnexal Masses (PV-5.3)**)
  - Lost IUD (inability to feel or see IUD string) with initial ultrasound (See **Intrauterine Device (PV-10.1)**)
  - Uterine anomaly is suspected on ultrasound (See **Uterine Anomalies (PV-14.1)**)
  - Infertility if ultrasound is indeterminate or there is clinical suspicion for intra-cavitary lesion (such as polyp or fibroid), hydrosalpinx, uterine synechia, adenomyosis or uterine anomalies (See **Initial Infertility Evaluation, Female (PV-9.1)**)
- 3D-4D (CPT® 76376 or CPT® 76377) rendering is medically necessary in certain situations of abnormal pregnancy implantation like suspected C-section scar pregnancies or suspected cornual (interstitial) ectopic pregnancy, or to locate an IUD.
- 3D-4D (CPT® 76376 or CPT® 76377) rendering is medically necessary for surgical planning with diagnosis of complex CHD in the fetus or for surgical planning of other complex fetal malformations.

Other Ultrasound

- CPT® 93975 Duplex scan (complete) of arterial inflow and venous outflow of abdominal, pelvic, scrotal contents and/or retroperitoneal organs; complete study.
- CPT® 93976 Duplex scan (limited) of arterial inflow and venous outflow of abdominal, pelvic, scrotal contents and/or retroperitoneal organs; limited study.
- CPT® 93975 and CPT® 93976 should not be reported together during the same session.

CT

- CT is not medically necessary for evaluating pelvic anatomy because it is limited due to soft tissue contrast resolution.

MRI

- Is medically necessary when used as a more targeted study or for individuals allergic to iodinated contrast.
  - MRI Pelvis without contrast (CPT® 72195)
  - MRI Pelvis without and with contrast (CPT® 72197)
  - MRI Pelvis with contrast only (CPT® 72196) is rarely performed

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion (PV-1.1)

- Ultrasonography and magnetic resonance imaging (MRI) are the imaging techniques of choice for the pregnant individual, they should be used prudently and only when use is expected to answer a relevant clinical question[11].
- CT is not generally warranted for evaluating pelvic anatomy because it is limited due to soft tissue contrast resolution. Computed tomography (CT) scans are generally not recommended during pregnancy unless the benefits clearly outweigh the potential risks[12]. Computed tomography (CT) scan if necessary in addition to ultrasonography or MRI if more readily available for the diagnosis in question, should not be withheld from a pregnant individual. The risk of adverse effects from ionizing radiation should always be weighed against the risk of not performing the procedure and the benefit derived from the procedure[12].
- Ultrasound is the recommended modality for imaging the female pelvic organs; no alternative modality has demonstrated sufficient superiority to justify routine use[3], and transvaginal ultrasound is the optimal study to evaluate adult female pelvic pathology. Transabdominal pelvic ultrasound is a useful complementary study to transvaginal ultrasound and may substitute for transvaginal ultrasound in pediatric individuals or non-sexually active females. The American Institute of Ultrasound in Medicine (AIUM.org) launched an initiative in 2012 "Ultrasound First," which advocates the use of ultrasound examinations before other imaging modalities when the evidence shows that ultrasound imaging is at least equally, if not more, effective for the target anatomic area[13]. This applies particularly to obstetric and gynecologic patients for whom a skillfully performed and well-interpreted ultrasound image usually obviates the need to proceed to additional more costly and complex cross-sectional imaging techniques[3].
- Transperineal ultrasound can be useful for cases of suspected urethral abnormalities, urinary incontinence, pelvic prolapse, or vaginal cysts[14,15]. A study by Yang, et al confirmed transvaginal or transperineal ultrasound to be a non-invasive and cost-effective modality for diagnosis of urethral and periurethral masses[14]. Vaginal and urethral imaging is limited on transvaginal ultrasound due to the position of the endovaginal probe rendering the vagina out of the field, on computed tomography (CT) due to poor soft tissue discrimination of the vaginal walls and on magnetic resonance imaging (MRI). MRI of the vagina should be done with thin slice thickness and proper choice of the degree of angulation and used MR sequence, otherwise there is limited evaluation of the vagina[15]. Transperineal ultrasound is also a dynamic real-time examination, and can detect subtle abnormalities that are not seen in static imaging[15].
- Scrotal ultrasound is supported for evaluation of scrotal pain or suspected mass[16,17]. The American Urological Association recommends scrotal ultrasound for initial evaluation of unilateral or bilateral scrotal mass suspicious for neoplasm[17].
- Three-dimensional (3D) rendering with ultrasound can be considered when ultrasound shows suspected uterine anomaly, uterine intra-cavitary lesion,

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

hydrosalpinges or peritoneal cysts[2,4,5,6]. A study by Laskshmy et al found 3D ultrasound to be a highly sensitive and specific tool for accurately diagnosing congenital uterine anomalies[2]. 3D rendering has shown a high degree of concordance with MRI and laparoscopy for congenital uterine anomalies, and is non-invasive, readily available and relatively cost-effective[4]. Three-dimensional ultrasound is a noninvasive method for evaluation of adnexal pathology[18].

- Doppler scan can be of benefit in addition to ultrasound for further evaluation of suspected uterine or ovarian abnormalities. Doppler flow mapping is useful in diagnosing submucosal fibroids and endometrial polyps[19]. ACOG (American College of Obstetrics and Gynecology)recommended that color Doppler ultrasonography is useful to evaluate the vascular characteristics of adnexal masses[1]. MRI pelvis is useful in cases such as inconclusive ultrasound for adenomyosis, "MRI is a second-line examination in the diagnosis of internal adenomyosis, mainly after a non-conclusive US evaluation. In addition, MRI can differentiate between the subtypes of adenomyosis." MRI pelvis is also useful for further evaluation of indeterminate adnexal masses. A study by Dirrichs, et al found MRI to improve sensitivity and specificity of diagnosis of indeterminate adnexal masses detected at TVUS, and use of MRI changed therapeutic management in 34% of cases[21]. MRI can aid in the diagnosis of deep pelvic endometriosis[22]. MRI pelvis is useful for further evaluation of unexplained pelvis pain when ultrasound evaluation is inconclusive[23]. Pelvic MRI is useful for evaluation of fibroids prior to uterine-sparing interventional techniques. "Although a high-quality ultrasonography (US) examination may be sufficient for evaluation in patients with straightforward cases of fibroids (for instance to estimate the size of a dominant fibroid), imaging evaluation is most reliably performed with magnetic resonance (MR) imaging to determine the characteristics, number, size, and location of fibroids and to assess for other pathologic conditions such as adenomyosis."[24]
- There is currently insufficient data to generate appropriateness criteria for the use of 3D and 4D rendering in conjunction with Obstetrical ultrasound imaging. Per ACOG, proof of a clinical advantage of 3-dimensional ultrasonography in prenatal diagnosis, in general, is still lacking.

Abnormal Uterine Bleeding (AUB) (PV-2.1)

PV.UB.0002.1.A
v2.0.2026

- Pregnancy test should be done initially if premenopausal
- If pregnancy test is negative or post menopausal initial evaluation includes ANY or ALL of the following:
  - Pelvic ultrasound (CPT® 76856 or CPT® 76857) and/or Transvaginal ultrasound (CPT® 76830), D&C and/or endometrial biopsy
- Advanced imaging is not medically necessary for Endometrial Intraepithelial Neoplasia or Atypical Endometrial Hyperplasia (EIN-AEH) as imaging has not been found to improve outcomes for this condition.
- In females assigned at birth with postmenopausal bleeding
  - Those with thickened endometrium on ultrasound, those whose ultrasound failed to identify a thin, distinct endometrial strip and/or those with continued vaginal bleeding should all undergo endometrial biopsy to rule out endometrial carcinoma
- If biopsy confirms a malignancy, then see the appropriate oncology guideline.
- If ultrasound is equivocal for intracavitary lesion the following is medically necessary:
  - Duplex (Doppler) scan (CPT® 93975 complete; CPT® 93976 limited) as an add-on to TV ultrasound (CPT® 76830).
  - 3-D Rendering (CPT® 76377 or CPT® 76376) as an add-on.
- CT is not generally warranted for evaluating AUB since uterine anatomy is limited due to soft tissue contrast resolution.
  - An abnormal endometrium found incidentally on CT should be referred for TV ultrasound for further evaluation.
- MRI is not indicated for evaluation of abnormal uterine bleeding, please see specific Pelvis Imaging sections for MRI indications for ultrasound findings such as adnexal mass or uterine fibroids. See **Adnexal Mass/Ovarian Cysts (PV-5)** and **Leiomyomata (PV-12.1)**.

Evidence Discussion (PV-2.1)

- Transabdominal pelvic and/or transvaginal pelvic ultrasound are widely accepted as the initial imaging modality of choice for evaluation of abnormal uterine bleeding[2,12]. Ultrasound also allows for real-time evaluation with color and power Doppler which can help identify vascular flow and distinguish fluid and cysts from soft tissue[12]. Additional benefits to ultrasound as a first line imaging modality include wide availability, fast access, and lack of ionizing radiation exposure. 3-D Rendering has

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

been shown to a useful adjunct for analysis of suspected lesions the endometrial cavity.

- MRI is not supported as an initial imaging modality for the diagnosis of abnormal uterine bleeding[12]. While MRI is accepted as an adjunct modality to ultrasound in cases where ultrasound may not fully characterize a soft tissue abnormality, imaging should be directed by the type of suspected soft tissue abnormality (i.e. adenomyosis, endometriosis, fibroids, and adnexal mass) and is addressed in additional sections of these guidelines. CT is of limited use in the evaluation of abnormal uterine bleeding given its suboptimal evaluation of the soft tissue of female pelvic organs[12].
- In premenopausal females assigned at birth presenting with abnormal uterine bleeding a pregnancy test should be performed. For those with a positive pregnancy test, imaging with appropriate obstetric ultrasound should be performed.
- Vaginal bleeding is the presenting symptom in 90% of postmenopausal females assigned at birth with endometrial cancer[10]. An endometrial strip of 4mm or less on ultrasound has been found to have a greater than 99% negative predictive value for endometrial cancer[10]. However, this cutoff may be inadequate in Black women, as it missed five-fold more cases than in White women[13]. Endometrial tissue sampling remains the gold standard for diagnosis of endometrial carcinoma. As such, those with thickened endometrium on ultrasound, those who ultrasound failed to identify a thin, distinct endometrial strip and those with continued vaginal bleeding should all undergo endometrial sampling to rule out endometrial carcinoma[10].
- The incidence of concurrent endometrial cancer with the diagnosis of Endometrial Intraepithelial Neoplasia or Atypical Endometrial Hyperplasia (EIN-AEH) is approximately 30% to 50%[1]. This makes evaluation for concurrent carcinoma imperative in the diagnosis of EIN-AEH for those considering a fertility-sparing treatment. The most accurate method for diagnosis is hysteroscopic-guided uterine sampling[1] which has the added benefit of direct visualization of any intrauterine pathology such as endometrial polyps.

Retained Products of Conception (PV-2.2)

PV.UB.0002.2.A

v2.0.2026

- For abnormal uterine bleeding and/or pelvic pain with concern for retained products of conception (RPOC):
  - Pelvic ultrasound (CPT® 76856 or CPT® 76857) and/or Transvaginal ultrasound (CPT® 76830) is medically necessary one time, repeat US is medically necessary for continued symptoms
  - Color Doppler ultrasonography (CPT® 93975 or CPT® 93976) may be added to ultrasound to aid in diagnosis of RPOC
  - CT Pelvis with and without contrast (CPT® 72194) OR MRI Pelvis with and without contrast (CPT® 72197) is medically necessary if US with Color Doppler is equivocal AND further imaging is needed for surgical planning

Evidence Discussion (PV-2.2)

- Transabdominal pelvic and/or transvaginal pelvic ultrasound are widely accepted as the initial imaging modality of choice for evaluation of suspected retained products of conception (RPOC)[15,16]. Ultrasound also allows for real-time evaluation with color and power Doppler which can help identify vascular flow within the endometrial complex, which improves the specificity and negative predictive value of detecting RPOC[15]. Additional benefits to ultrasound as a first line imaging modality include wide availability, fast access, and lack of ionizing radiation exposure.
- For most cases ultrasound is sufficient for detection of RPOC. For cases where ultrasound is inconclusive additional imaging with MRI or CT may provide additional information to aid in surgical planning[16].

Secondary Amenorrhea (PV-3.1)

PV.AM.0003.1.A
v2.0.2026

- Pregnancy test should be done initially
- If a pregnancy test is positive:
  - Refer to the member's individual coverage policy regarding obstetrical imaging indications and appropriate obstetrical imaging procedural codes. Billing of gynecology codes during pregnancy is not supported.
- If a pregnancy test is negative, further evaluation includes any of the following:
  - FSH, TSH, estradiol, and/or prolactin levels are medically necessary depending on clinical suspicion.
  - Serum free and total testosterone and/or DHEAS levels are indicated if there is evidence of hyperandrogenism
  - Pelvic ultrasound (CPT® 76856 or CPT® 76857) and/or TV ultrasound (CPT® 76830) for suspected uterine or ovarian pathology are medically necessary
- The results of test(s) above determine the next steps, which include:
  - For suspected adrenal tumor, See **Adrenal Cortical Lesions (AB-16)** in the Abdomen Imaging Guidelines.
  - For suspected pituitary tumor or hypothalamic, See **Pituitary, Sella, Hypothalamus(HD-19)** in the Head Imaging Guidelines
  - For suspected Asherman's Syndrome the following are medically necessary:
    - Hysterosalpingogram (CPT® 74740), sonohysterosalpingography (CPT® 76831), and/or hysteroscopy if ultrasound is indeterminate for Asherman's syndrome
    - MRI Pelvis without contrast (CPT® 72195) or without and with contrast (CPT® 72197) if hysterosalpingogram (CPT® 74740), sonohysterosalpingography (CPT® 76831), or hysteroscopy is indeterminate for Asherman's Syndrome.

Background and Supporting Information

- Asherman's syndrome: an acquired condition which refers to having scar tissue in the uterus

Primary Amenorrhea (PV-3.2)

PV.AM.0003.2.A

v2.0.2026

- Prior to imaging a history, physical examination and Tanner stage should be evaluated.
- Initial evaluation may include pelvic ultrasound (CPT® 76856 or CPT® 76857) and/or TV ultrasound (CPT® 76830) as medically necessary if ANY of the following:
  - Normal pubertal development and negative pregnancy test
  - Pelvic exam is indeterminate or unable to be performed
  - Delayed puberty with follicle-stimulating hormone (FSH) or luteinizing hormone (LH) that is elevated for the individual's age and Tanner stage
- If ultrasound defines a uterine or vaginal anomaly see **Uterine Anomalies (PV-14.1)**
- For suspected pituitary or hypothalamic tumor, See **Pituitary, Sella, Hypothalamus (HD-19)** in the Head Imaging Guidelines

Background and Supporting Information

- Evaluation of an individual without a uterus (determined by imaging or examination) may include karyotype and/or testosterone levels.
- TV ultrasound (CPT® 76830) is medically necessary in pediatric individuals who are sexually active or use a tampon and consent to the study.

Evidence Discussion (PV-3)

- The initial work up of amenorrhea should include a physical exam, pregnancy test and hormonal work up. For those with a positive pregnancy test, imaging with obstetric ultrasound should be performed. Hormonal testing can help to further direct imaging[7,2,5,6].
- Transabdominal pelvic and/or transvaginal pelvic ultrasound are widely accepted as the initial imaging modality of choice for evaluation of amenorrhea[7,2,5,6]. Ultrasound also allows for real-time evaluation with color and power Doppler which can help identify vascular flow and distinguish fluid and cysts from soft tissue[7]. Additional benefits to ultrasound as a first line imaging modality include wide availability, fast access, and lack of ionizing radiation exposure.
- MRI is supported as an adjunct to inconclusive ultrasound imaging, especially if the ultrasound is suggestive of a congenital uterine or vaginal anomaly[2]. CT is of limited use in the evaluation of amenorrhea given its suboptimal evaluation of the soft tissue of female pelvic organs.
- For suspected Asherman's syndrome, the gold standard for diagnosis remains hysteroscopy which has the added benefit of allowing for simultaneous treatment of adhesive disease[8,9]. However, hysteroscopy carries with it risks of anesthesia and

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

uterine perforation. Hysterosaplingogram (HSG) allows for simultaneous evaluation of tubal patency[8]. Sonohsyterography (SHG) has a high negative predictive value (98%), but only a modest positive predictive value (43%)[8]. MRI may be a useful adjunct to HSG, SHG and hysteroscopy, especially in cases where there is complete obstruction of the endometrial cavity limiting the diagnostic ability of these tests[8,9].

Adenomyosis (PV-4.1)

PV.AD.0004.1.A
v2.0.2026

- TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76856 or CPT® 76857) is the medically necessary diagnostic procedure of choice for the initial evaluation of suspected adenomyosis. Duplex Doppler (CPT® 93975 or CPT® 93976) can be added if requested.
- MRI Pelvis without contrast (CPT® 72195) or MRI Pelvis without and with contrast (CPT® 72197) is considered a medically necessary second-line imaging option after transvaginal ultrasound if:
  - Diagnosis is inconclusive for adenomyosis after an ultrasound and further delineation would affect management
  - MRI needed to guide the treatment of adenomyosis in an individual with an enlarged uterus, and coexisting leiomyoma/fibroid following indeterminate ultrasound
  - Uterine artery embolization is being considered
    - If MRI is equivocal, MRA Pelvis (CPT® 72198) or CTA Pelvis (CPT® 72191) if requested by or in consultation with the interventional radiologist planning the uterine artery embolization

Background and Supporting Information

Adenomyosis is when endometrial tissue, which normally lines the uterus, moves into the outer muscular walls of the uterus. Adenomyosis is a histologic diagnosis and is suspected by history and physical examination. Ultrasound findings of adenomyosis include heterogeneous myometrium, myometrial cysts, asymmetric myometrial thickness, and subendometrial echogenic linear striations.

Evidence Discussion (PV-4.1)

- Transabdominal pelvic and/or transvaginal pelvic ultrasound are widely accepted as the initial imaging modality of choice for evaluation of adenomyosis[10,1,2,3]. Ultrasound also allows for real-time evaluation with color and power Doppler which can help identify vascular flow and distinguish fluid and cysts from soft tissue[10]. In the presence of features mimicking leiomyomas, Doppler US displaying vessels perpendicular to the endometrial interface, is suggestive of adenomyosis[2]. Transvaginal ultrasound has a sensitivity of 83.8% and specificity of 63.9% for adenomyosis[7,8]. The overall diagnostic accuracy of the use of transvaginal ultrasound with color Doppler for adenomyosis is 93.8%[8]. Additional benefits to ultrasound as a first line imaging modality include wide availability, fast access, and lack of ionizing radiation exposure.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- MRI of the pelvis is a second-line examination in the diagnosis of adenomyosis, mainly after an inconclusive US evaluation[2]. MRI pelvis is useful in individuals with coexisting leiomyoma[2]. A meta-analysis comparing the diagnostic performance of MRI and transvaginal ultrasound reported that MRI had a pooled sensitivity of 77% and a specificity of 89%[2]. The authors concluded that MRI performs more favorably than transvaginal ultrasound in the presence of associated uterine leiomyomas[2].

Suspected Adnexal Mass – Initial Evaluation (PV-5.1)

PV.MC.0005.1.A
v2.0.2026

- A potential mass is found on exam and/or found incidentally on other imaging
- Transvaginal (TV) ultrasound imaging (CPTCPT® 76830) is the medically necessary initial study of choice.
  - Pelvic ultrasound (CPT® 76856 or CPT® 76857) can be performed if requested as a complimentary study to the TV ultrasound.
  - Once confirmed, Color Doppler ultrasonography (CPT® 93975 or CPT® 93976) may be medically necessary to evaluate the vascular characteristics of adnexal masses.
- MRI Pelvis without contrast (CPT® 72195), OR without and with contrast (CPT® 72197; CPT® 72195 if pregnant) is medically necessary if ultrasound does not identify the origin of the pelvic mass (adnexal, uterine, or other in etiology).
  - If the mass is unrelated to female pelvic organ anatomy, see **Abdominal Mass (AB-13)** in the Abdomen Imaging Guidelines.
- For O-RADS™ 0 (incomplete evaluation) either repeat ultrasound OR MRI Pelvis without contrast (CPT® 72195), OR without and with contrast (CPT® 72197)is medically necessary
  - If pregnant, MRI pelvis without contrast CPT® 72195 is medically necessary to avoid gadolinium exposure to the fetus.

Background and Supporting Information

- Consultation with or referral to a gynecologic oncologist is recommended for females assigned at birth with an adnexal mass who meet one or more of the following criteria:[7]
  - Postmenopausal with elevated CA-125 level, ultrasound findings suggestive of malignancy, ascites, a nodular or fixed pelvic mass, or evidence of abdominal or distant metastasis.[7]
  - Premenopausal with very elevated CA-125 level, ultrasound findings suggestive of malignancy, ascites, a nodular or fixed pelvic mass, or evidence of abdominal or distant metastasis.[7]
  - Premenopausal or postmenopausal with an elevated score on a formal risk assessment test such as the multivariate index assay, risk of malignancy index, or the Risk of Ovarian Malignancy Algorithm or one of the ultrasound-based scoring systems from the International Ovarian Tumor Analysis group.[7]

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- O-RADS™ 0 should not be used for masses that are completely visualized but the diagnosis is unclear.
- Simple and Complex Adnexal Cysts
  - Simple cysts are smooth walled and clear without debris.
  - Complex cysts can have solid areas or excrescences, and/or debris in them, greater than 3mm irregular septations, mural nodules with Doppler-detected blood flow, and/or free abdominal/pelvic fluid.
- Suspected Adnexal Mass – Tumor Markers
  - The adnexa include the ovaries, Fallopian tubes, and ligaments that hold the uterus in place.
  - CA-125 is a tumor marker that is useful for the evaluation of adnexal mass:
    - Elevation occurs with both malignant (epithelial cancer) and benign entities (leiomyoma, endometriosis, PID, inflammatory disease such as lupus, and inflammatory bowel disease).
    - Increase in the markers over time occurs with malignancy only
    - Consider tumor markers in individuals with an abnormal ultrasound that is not a simple cyst
  - Other markers include Beta hCG, LDH, and AFP (germ cell tumors) and Inhibin A and B (granulosa cell tumor).

Simple Cysts (PV-5.2)

PV.MC.0005.2.A
v2.0.2026

- Simple cysts are smooth, thin walled, anechoic and clear without debris. Simple cysts up to 10 cm in diameter as measured by ultrasound are almost universally benign.
  - Repeat TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76857 or CPT® 76856) is medically necessary
    - Follow up according to the below schedule if ≤10 cm
  - Routine use of 3D rendering (CPT® 76376/CPT® 76377) for evaluation of simple ovarian cysts is not medically necessary.

Simple Cyst Follow-Up

Size	Pre-Menopausal	Post-Menopausal
≤3 cm	• None	• None
>3 cm to 5 cm	• None	• Follow-up in 12 months with TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76857 or CPT® 76856) is medically necessary: ◦ If smaller (≥10-15% decrease) no further surveillance. ◦ If stable follow-up TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76857 or CPT® 76856) at 24 months from initial exam ◦ If enlarging (≥10%-15% increase) follow-up TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76857 or CPT® 76856) at 12 and 24 months from initial exam • If there is a change in morphology on follow imaging see **Complex Adnexal Masses (PV 5.3)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Size	Pre-Menopausal	Post-Menopausal
>5 cm to ≤10 cm	• Follow up in 8-12 weeks (proliferative phase if possible) with TV ultrasound (CPT® 76830) and/ or Pelvic ultrasound (CPT® 76857 or CPT® 76856) is medically necessary; further follow-up intervals may be adjusted on basis of degree of cyst change	• Follow-up in 3-6 months with TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76857 or CPT® 76856) is medically necessary; further follow-up intervals may be adjusted on basis of degree of cyst change. • Subsequent follow up with TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76857 or CPT® 76856) is medically necessary annually and if stable for 2 years or decreasing in size, no further imaging follow-up is needed.

Complex Adnexal Masses (PV-5.3)

PV.MC.0005.3.A

v2.0.2026

- Ultrasound imaging should provide characteristics of the cyst/mass prior to consideration of advanced imaging.
- Complex cysts found on ultrasound have characteristics that include: solid areas or excrescences, and/or debris, may have greater than 3mm irregular septations, and/or mural nodules with Doppler-detected blood flow, and/or free abdominal/pelvic fluid. Complex cysts have an O-RADS™ score of 2 or higher.
- Routine use of 3D rendering (CPT® 76376/CPT® 76377) for evaluation of complex ovarian cysts is not medically necessary unless otherwise mentioned in the table below.

Follow up Complex Adnexal Masses

Condition	Pre-Menopausal	Post-Menopausal
Typical hemorrhagic cyst < 10 cm (O-RADS™ 2)	• If initial ultrasound imaging confirms hemorrhagic cyst ≤5 cm no further imaging is medically necessary • If initial ultrasound imaging confirms hemorrhagic cyst >5 cm but <10 cm, follow up with Pelvic ultrasound (CPT® 76856 or CPT® 76857) and/or TV ultrasound (CPT® 76830) in 8-12 weeks is medically necessary. Duplex (Doppler) scan (CPT® 93975 complete; CPT® 93976 limited) may be approved as an add-on to TV ultrasound (CPT® 76830). ◦ If follow-up imaging confirms a hemorrhagic cyst that has not completely resolved or has enlarged, MRI Pelvis without and with contrast (CPT® 72197) is medically necessary. ◦ If stable, follow up TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76857 or CPT® 76856) is medically necessary at 24 months from initial exam	• Early postmenopausal (<5 years) either of the following is medically necessary: ◦ follow-up TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76857 or CPT® 76856) in 2-3 months OR ◦ MRI Pelvis without and with contrast (CPT® 72197) • Late postmenopausal (≥ 5 years) hemorrhagic cyst should not occur ◦ MRI Pelvis without and with contrast (CPT® 72197) is medically necessary

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Condition	Pre-Menopausal	Post-Menopausal
Hemorrhagic cyst ≥10cm (O-RADS™ 3)	• If ultrasound equivocal for Hemorrhagic cyst, MRI Pelvis without and with contrast (CPT 72197) • If initial ultrasound imaging confirms a Typical Hemorrhagic cyst ≥10cm ◦ If not excised consider TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76857 or CPT® 76856) follow up within 6 months ▪ If stable, follow up Ultrasound can be done at 12 and 24 months from initial exam ◦ If solid component, MRI Pelvis without and with contrast (CPT® 72197) may be approved ◦ If follow up ultrasound imaging shows changing morphology and/or a vascular component then consider MRI Pelvis without and with contrast (CPT® 72197)	• MRI Pelvis without and with contrast (CPT® 72197) is supported

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Condition	Pre-Menopausal	Post-Menopausal
Typical Endometriomas < 10cm (O-RADS™ 2)	• If ultrasound equivocal for Endometriomas, MRI Pelvis without and with contrast (CPT 72197) • If initial imaging confirms a Typical Endometrioma, follow-up Pelvic ultrasound (CPT® 76856 or CPT® 76857) and/or TV ultrasound (CPT® 76830); duplex (Doppler) scan (CPT® 93975 complete; CPT® 93976 limited) may be approved as an add-on to TV ultrasound (CPT® 76830) ◦ If <10cm and not surgically excised follow-up TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76857 or CPT® 76856) in 12 months ▪ If stable follow up Ultrasound can be done at 24 months from initial exam ◦ If follow up ultrasound imaging shows changing morphology and/or a vascular component then consider MRI Pelvis without and with contrast (CPT® 72197)	• If initial ultrasound imaging confirms a typical endometrioma < 10cm then either the following is medically necessary: ◦ Follow-up TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76857 or CPT® 76856) in 2-3 months OR ◦ MRI Pelvis without and with contrast (CPT® 72197)
Typical Endometriomas ≥10cm (O-RADS™ 3)	• If initial ultrasound imaging confirms a Typical Endometrioma ≥10cm the following is medically necessary: ◦ If not excised, TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76857 or CPT® 76856) follow up within 6 months ▪ If stable follow up Ultrasound can be done at 12 and 24 months from initial exam ◦ If solid component, MRI Pelvis without and with contrast (CPT® 72197) may be approved ◦ CPT® 72197) ◦ If follow up ultrasound imaging shows changing morphology and/or a vascular component then consider MRI Pelvis without and with contrast (CPT® 72197)	• MRI Pelvis without and with contrast (CPT® 72197) is medically necessary

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Condition	Pre-Menopausal	Post-Menopausal
Typical Dermoid < 10cm (O-RADS™ 2)	• If initial features are only suggestive for, or if assessment is uncertain follow-up Pelvic ultrasound (CPT® 76856 or CPT® 76857) and/or TV ultrasound (CPT® 76830) within 3 months is medically necessary • OR • If ultrasound equivocal for Dermoid, MRI Pelvis without and with contrast (CPT 72197) is medically necessary • If initial ultrasound imaging confirms a Dermoid, follow-up Pelvic ultrasound (CPT® 76856 or CPT® 76857); and/or TV ultrasound (CPT® 76830); duplex (Doppler) scan (CPT® 93975 complete; CPT® 93976 limited) may be medically necessary as an add-on to TV ultrasound (CPT® 76830). ◦ If ≤10 cm, may consider follow-up TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76857 or CPT® 76856) in 12 months if not surgically excised ▪ If stable follow up Ultrasound can be done at 24 months from initial exam ◦ If follow up ultrasound imaging shows changing morphology and/or a vascular component then consider MRI Pelvis without and with contrast (CPT® 72197)	• Same as Pre-Menopausal

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Condition	Pre-Menopausal	Post-Menopausal
Typical Dermoid ≥ 10cm (O-RADS™ 3)	• If ultrasound equivocal for Dermoid, MRI Pelvis without and with contrast (CPT 72197) • If initial ultrasound imaging confirms a Typical Dermoid ≥10cm ◦ If not excised consider TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76857 or CPT® 76856) follow up within 6 months ▪ If stable follow up Ultrasound can be done at 12 and 24 months from initial exam ◦ If solid component, MRI Pelvis without and with contrast (CPT® 72197) may be approved ◦ If follow up ultrasound imaging shows changing morphology and/or a vascular component then consider MRI Pelvis without and with contrast (CPT® 72197)	• Same as Pre-Menopausal
Typical benign extraovarian lesions Hydrosalpinges (Hydrosalpinx) or Peritoneal cysts (ORADS™ 2)	• If initial imaging confirms hydrosalpinx or peritoneal cysts, follow up imaging is not medically necessary	• If initial imaging confirms hydrosalpinx or peritoneal cysts, follow up imaging is not medically necessary

Complex and/or solid adnexal mass incompletely evaluated by ultrasound

- Generally a repeat ultrasound is medically necessary (see table above for appropriate time intervals): TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76857 or CPT® 76856)
- MRI Pelvis without and with contrast (CPT® 72197, CPT® 72195 if pregnant) one time is medically necessary as follows:
  - To follow masses when they cannot be optimally visualized by ultrasound (e.g. suboptimal sonography due to large mass or obese individual)
  - Unexplained change of appearance during ultrasound follow-up

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Other Individual-driven indications (e.g. the application of established risk prediction models (e.g., family history of ovarian cancer), correlation with abnormal serum biomarkers, and/or pelvic symptoms)
  - Differentiate the origin of pelvic masses that are not clearly of ovarian origin
  - O-RADS™ score of 3 with a solid component
  - O-RADS™ score of 4 or 5
- Concern for metastatic ovarian malignancy, see **Ovarian Cancer (ONC-21)** in the Oncology Imaging Guidelines

Background and Supporting Information

O-RADS™ Classification

O-RADS	
O-RADS™ 0	Incomplete Evaluation
O-RADS™ 1	Normal Ovary • No ovarian lesion • Physiologic cyst: follicle ≤3cm or corpus luteum typically ≤3cm
O-RADS™ 2	Almost Certainly Benign • Simple cyst less than 10 cm • Bilocular, smooth cyst • Unilocular, smooth, non-simple cysts (internal echos and/or incomplete septations) • Typical benign ovarian lesions <10cm (hemorrhagic cyst, dermoid cyst, endometrioma) • Typical benign extraovarian lesions (paraovarian cyst, peritoneal inclusion cysts, hydrosalpinx)
O-RADS™ 3	Low Risk • Typical benign ovarian lesions ≥10cm • Uni- or bilocular cyst, smooth, ≥10cm • Unilocular cyst, irregular, any size • Multilocular cyst, smooth, <10cm, Color Score (CS) <4 • Solid lesion, ± shadowing, smooth, any size, CS =1 • Solid lesion, shadowing, smooth, any size, CS 2-3

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

O-RADS	
ORADS™ 4	Intermediate Risk • Bilocular cysts without solid component(s), Irregular, any size, any color score • Multilocular cysts without solid component(s) ◦ Smooth, 10 cm, CS <4 ◦ Smooth, any size, CS 4 ◦ Irregular, any size, any CS • Unilocular cyst with solid component(s) ◦ <4 papillary projections or any solid component(s) not considered a papillary projection, any size • Bl- or multilocular cyst with solid component(s), any size, CS 1-2 • Solid lesion, non-shadowing, smooth, any size, CS 2-3
ORADS™ 5	High Risk • Unilocular cyst, ≥4 papillary projections, any size, and CS • Bi- or multilocular cyst with solid component(s), any size, CS 3-4 • Solid lesion, ± shadowing, smooth, any size, CS 4 • Solid lesion, irregular, any size, any CS • Ascites and/or peritoneal nodules

Pre-Menopausal – see table above

- For females assigned at birth of reproductive age (Pre-Menopausal), evaluation may include a pregnancy test (a quantitative hCG may be necessary if an ectopic pregnancy is suspected), CBC, serial hematocrit measurements, and appropriate cultures.
- Symptomatic individuals often require immediate interventions (antibiotics, surgery, and/or expectant management).
- Ultrasound characteristics usually suggest the diagnosis (ectopic pregnancy, functional cysts, tubo-ovarian abscess (See **Pelvic Inflammatory Disease (PV-7.1)**), hydrosalpinx, dermoid, endometrioma, hemorrhagic cyst and pedunculated fibroids (See **Leiomyoma/Uterine Fibroids (PV-12.1)**) and direct the treatment.
- An ovarian mass suspicious for metastatic disease (e.g. from breast, uterine, colorectal or gastric cancer) should be evaluated based on the appropriate Oncology Imaging Guidelines.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Post-Menopausal – see table above

- For post-menopausal females assigned at birth, most pelvic complex cysts or solid masses should be evaluated for surgical intervention and have tumor markers (i.e. CA-125) measured.
- Some for whom the usual management of a pelvic mass would include surgery may be at increased risk for perioperative morbidity and mortality. In such cases, repeat imaging may be a safer alternative than immediate surgery, although the frequency of follow-up imaging has not been determined.
- An ovarian mass suspicious for metastatic disease (e.g. from breast, uterine, colorectal or gastric cancer) should be evaluated based on the appropriate Oncology Imaging Guidelines.

Screening for Ovarian Cancer/Suspected Ovary Cancer (PV-5.4)

PV.MC.0005.4.A
v2.0.2026

- See **Ovarian Cancer (ONC-21)** in the Oncology Imaging Guidelines

Evidence Discussion (PV-5)

- Transabdominal pelvic and/or transvaginal pelvic ultrasound are widely accepted as the initial imaging modality of choice for female reproductive organs[3,14]. Ultrasound has high sensitivity (>90%) for adnexal pathology[14]. Ultrasound also allows for real-time evaluation with color and power Doppler which can help identify vascular flow and differentiate solid components[2]. Additional benefits to ultrasound as a first line imaging modality include wide availability, fast access and lack of ionizing radiation exposure. MRI is accepted as an adjunct modality to ultrasound in cases where ultrasound may not fully characterize a soft tissue abnormality due to its superior signal to noise ratio[14,15,16]. CT is of limited use in the evaluation of adnexal masses given its suboptimal delineation of adnexal soft tissue[14].
- Accurate diagnosis of adnexal pathology is imperative in order to limit invasive interventions for benign lesions[15] and improve preoperative triage to a gynecologic oncologist for high-risk lesions. In order to standardize reporting of adnexal lesions, the American College of Radiology (ACR) has created the Ovarian-Adnexal Reporting and Data-System (O-RADS)[7]. A meta-analysis of 26 studies demonstrated that O-RADS has high sensitivity for detection of malignancy (95%)[4]. A classification of O-RADS US Category 2 has an extremely low risk of malignancy (<1%), while a Category 5 has a high risk of malignancy (≥50%)[16]. For an indeterminate lesion on ultrasound or features concerning for malignancy, adjunct imaging with MRI is supported to aid in preoperative triage.

Endometriosis (PV-6.1)

PV.EM.0006.1.A

v2.0.2026

- TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76856 or CPT® 76857) is medically necessary as the first line diagnostic exam for suspected endometriosis.
- MRI Pelvis without contrast (CPT® 72195) or without and with contrast (CPT® 72197) is medically necessary as follows:
  - Prior to planned surgery for suspected deep pelvic endometriosis such as rectovaginal endometriosis, deeply infiltrative bladder endometriosis, and cul-de-sac obliteration.
  - To characterize complex adnexal masses as endometrioma if ultrasound equivocal See **Complex Adnexal Masses (PV-5.3)**
- If known or suspected thoracic endometriosis, see **Pneumothorax/Hemothorax (CH-19.1)**in the Chest Imaging Guidelines.

Evidence Discussion (PV-6.1)

- Transabdominal pelvic and/or transvaginal pelvic ultrasound (TVUS) are widely accepted as the initial imaging modality of choice for evaluation of endometriosis[2,4,5,7]. A meta-analysis by Hudelist et al found transvaginal ultrasound was found to have a sensitivity and specificity of 91 and 98%, respectively, with a positive predictive value of 98% and negative predictive value of 95%[2]. A study by Goncalves et al compared TVUS done preoperatively to diagnostic laparoscopy for deep and ovarian endometriosis[7]. This study found TVUS to be accurate in identifying all sites of ovarian and deep endometriosis, with significantly higher sensitivity than diagnostic laparoscopy in detecting rectosigmoid endometriosis. Additional benefits to ultrasound as a first line imaging modality include wide availability, fast access, and lack of ionizing radiation exposure.
- MRI of the pelvis can be useful for cases of suspected deep pelvic endometriosis[5,3]. A study by Macario et al found MRI of the pelvis prior to laparoscopy to have an overall sensitivity of 91.9% and specificity of 91.2% in the preoperative diagnosis of deep pelvic endometriosis with cul-de-sac obliteration[3]. MRI is also indicated for further evaluation of suspected endometrioma of the ovary if ultrasound is equivocal[11,12]. The American College of Radiology (ACR) Appropriateness Criteria for adnexal mass states, "When an adnexal mass is indeterminate on US, either the organ of origin is uncertain or it is unclear whether the mass is benign or malignant, then MRI with intravenous (IV) contrast (if feasible) becomes the modality of choice.[12]" Per the ACR Appropriateness Criteria, "MRI can readily diagnose typical endometriomas." A study by Dirrichs et al found MRI to improve sensitivity and specificity of diagnosis for indeterminate adnexal masses found with TVUS[13]. In this study, MRI changed the management decision in 34% of patients[13].

Pelvic Inflammatory Disease (PV-7.1)

PV.PI.0007.1.A
v2.0.2026

- Clinical examination alone is usually sufficient for confirming the diagnosis of pelvic inflammatory disease. See **Pelvic Pain/Dyspareunia, Female (PV-11.1)** if other causes of pelvic pain are suspected.
- Pelvic ultrasound (CPT® 76856 or CPT® 76857) and/or TV ultrasound (CPT® 76830) is medically necessary as the initial study for imaging of suspected pelvic inflammatory disease (PID) if diagnosis is uncertain following bimanual pelvic examination and laboratory testing (such as WBC, CRP and ESR, Microscopy of the vaginal secretions, and testing for Neisseria gonorrhoeae and Chlamydia trachomatis) OR for suspected Tubo-Ovarian Abscess (TOA). Color Doppler ultrasonography (CPT® 93975 or CPT® 93976) may be added.
- CT Pelvis with contrast (CPT® 72193) or MRI Pelvis with and without contrast (CPT® 72197) is medically necessary:
  - If diagnosis is uncertain following examination, laboratory testing and ultrasound
  - Ultrasound shows extensive abscess formation and further imaging is needed for treatment planning
  - Suspected TOA with inconclusive ultrasound
- If suspected abdominal abscess see **Abdominal Sepsis (Suspected Abdominal Abscess) (AB-3.1)**in the Abdomen Imaging Guidelines.

Background and Supporting Information

PID may be clinically suspected based on findings of abdominal and/or pelvic pain, cervical or vaginal mucopurulent discharge, dyspareunia, inter-menstrual and/or post coital bleeding, fever, low back pain, nausea/vomiting, urinary frequency, cervical motion tenderness, uterine and/or adnexal tenderness on exam.

Laboratory findings may include elevated erythrocyte sedimentation rate, elevated C-reactive protein, lab documentation of cervical infection with N. gonorrheae or C. trachomatis, WBC on saline microscopy of vaginal fluid, and/or endometrial biopsy with endometritis.

Evidence Discussion (PV-7.1)

- Clinical examination and laboratory testing are appropriate in the initial diagnostic testing for suspected pelvic inflammatory disease (PID)[2,7,10]. Imaging studies can be helpful when further evaluation is needed and to rule out other differential diagnoses such as ovarian cysts or gastrointestinal disease[2,7,10].

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Transabdominal pelvic and/or transvaginal pelvic ultrasound are widely accepted as the initial imaging modality of choice for evaluation of pelvic inflammatory disease[2,7,10,8,9]. Additional benefits to ultrasound as a first line imaging modality include wide availability, fast access, and lack of ionizing radiation exposure. The addition of Power Doppler to ultrasonography has been found to increase sensitivity in the diagnosis of PID[2,7,8,9].
- CT Pelvis or MRI Pelvis can be considered if further imaging is needed following inconclusive ultrasound for diagnosis of PID, suspected tubo-ovarian abscess, or to evaluate for the extent of PID abscess formation for treatment planning[2,7,8,9,6,4].

Polycystic Ovary Syndrome (PCOS) (PV-8.1)

PV.PC.0008.1.A

v2.0.2026

- Pelvic ultrasound (CPT® 76856 or CPT® 76857) and/or TV ultrasound (CPT® 76830) is medically necessary when history, exam, and/or laboratory findings are suspicious for PCOS.
- Laboratory testing to be done prior to advanced imaging: Virilizing hormone levels (Testosterone and DHEAS). Disorders that mimic the clinical features of Polycystic ovary syndrome (PCOS) should be excluded by measuring: TSH, Prolactin, and 17-OHP (hydroxyprogesterone) levels. Others to consider based on the clinical presentation: Cortisol levels, ACTH, dexamethasone suppression testing, IGF-1, FSH, LH, estradiol.
- If elevated serum levels of androgens are found and an adrenal etiology is suspected - see **Adrenal Cortical Lesions (AB-16.1)** in the Abdomen Imaging Guidelines.

Background and Supporting Information

- Polycystic ovary syndrome is the most common hormonal disorder among females of reproductive age, and is one of the leading causes of infertility.
- Diagnostic criteria of polycystic ovary syndrome (Two of the following three criteria are required):
  - Oligo/anovulation
  - Hyperandrogenism
    - Clinical (hirsutism or less commonly male pattern alopecia) or
    - Biochemical (raised FAI (free androgen index) or free testosterone)
  - Polycystic ovaries on ultrasound
    - Defined as an ovary containing 12 or more follicles (or 25 or more follicles using new ultrasound technology) measuring 2 to 9 mm in diameter or an ovary that has a volume of greater than 10 mL on ultrasonography. A single ovary meeting either or both of these definitions is sufficient for diagnosis of polycystic ovaries.
- Clinical Features of PCOS
  - Hirsutism and male pattern balding consistent with hyperandrogenism
  - Irregular or absent menstrual cycles
  - Subfertility or infertility
  - Psychological symptoms – anxiety, depression, psychosexual dysfunction, eating disorders
  - Metabolic features – obesity, dyslipidaemia, diabetes

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Evidence Discussion (PV-8)

- Transabdominal pelvic and/or transvaginal pelvic ultrasound are widely accepted as the modality of choice for evaluation of the ovaries in patients with suspected polycystic ovarian syndrome (PCOS)[1,2,3,6]. Ultrasound allows for real-time evaluation of the pelvic anatomy, has wide availability, fast access, and lack of ionizing radiation exposure. It also allows for follicular count which will help establish the diagnosis of PCOS[1,2,3,6].
- Laboratory testing may point to other etiology of symptoms and may better direct additional imaging[1,2,3,6].
- Imaging for suspected adrenal pathology is addressed in the Abdominal Section of these guidelines.

Initial Infertility Evaluation, Female (PV-9.1)

PV.IE.0009.1.A
v2.0.2026

This guideline is not intended for fertility treatment follow-up and management. See individual fertility coverage policy for imaging during active fertility treatment.

- A one-time Pelvic ultrasound (CPT® 76856 or CPT® 76857) and/or TV ultrasound (CPT® 76830) is medically necessary for initial infertility workup.
  - Repeat ultrasounds or serial ultrasounds are not medically necessary for initial infertility workup
- To evaluate for tubal patency:
  - Hysterosalpingography (HSG) (CPT® 74740) **or** Sonohysterosalpingography (CPT® 76831) is medically necessary
- If ultrasound is indeterminate or there is clinical suspicion for intra-cavitary lesion (such as polyp or fibroid), hydrosalpinx, uterine synechia, adenomyosis or uterine anomalies either of the following are medically necessary:
  - 3D US imaging (add-on CPT® 76376 or CPT® 76377)
  - US Color Doppler (CPT® 93975 or CPT® 93976)

Background and Supporting Information

Some payors do not provide coverage for infertility evaluation and/or treatment.

Evidence Discussion (PV-9)

- Transabdominal pelvic and/or transvaginal pelvic ultrasound are widely accepted as the initial imaging modality of choice for evaluation of the female pelvic organs[1,2,5,6,8]. Ultrasound allows for real-time evaluation, has wide availability, fast access, and lack of ionizing radiation exposure[1]. The addition of 3D ultrasound is beneficial in cases when intrauterine abnormalities are suspected[5,3,4]. The diagnostic accuracy of 3D ultrasound is 90% to 95% for uterine anomalies[5]. Adding Doppler evaluation provides information about vascularity and tissue perfusion[5,7].
- Hysterosalpingography (HSG) or Sonohysterosalpingography can be utilized in assessing tubal patency. Sonohysterosalpingography is more operator dependent than HSG, however, both procedures benefit patients in that they can help avoid the more invasive laparoscopy and chromotubation, which carry the risks of surgery and anesthesia[6,8].

Intrauterine Device (PV-10.1)

PV.ID.0010.1.A
v2.0.2026

- Pelvic ultrasound (CPT® 76856 or CPT® 76857) and/or TV ultrasound (CPT® 76830) is medically necessary if:
  - Abnormal pelvic exam prior to IUD insertion, such as pelvic mass, irregularly shaped uterus, or enlarged uterus
  - Suspected IUD complication:
    - Abnormal IUD position
    - Uterine perforation
    - Severe pain
    - Excessive bleeding
    - Suspected infection

"Lost" IUD inability to palpate IUD string on pelvic exam, and/or see IUD on speculum exam:

- If unable to palpate, see or retrieve IUD string on pelvic exam and/or speculum exam an attempt to retrieve IUD strings with cytobrush or instrumentation of the cervix should be undertaken prior to imaging.:
  - TV ultrasound CPT® 76830 and/or Pelvic ultrasound (CPT® 76856 or CPT® 76857); with or without 3-D Rendering (CPT® 76377 or CPT® 76376) is medically necessary:
    - If TV and/or Pelvic ultrasound is negative or non-diagnostic, plain x-ray should be performed if pregnancy test is negative
      - If IUD is not visualized on x-ray a diagnosis of expulsion can be made
    - CT Pelvis without contrast (CPT® 72192) or CT Abdomen and Pelvis without contrast (CPT® 74176) or MRI Pelvis without contrast (CPT® 72195) is medically necessary when both ultrasound and plain x-ray are equivocal or non-diagnostic as it may be useful to delineate IUD position and relationship to other abdominal organs.
- If pregnancy test is positive:
  - The use of gynecology CPT codes for pregnant females is not supported. Therefore, transvaginal ultrasound (CPT® 76830) and pelvic ultrasound (CPT® 76856 or CPT® 76857) are not medically necessary for those with a positive pregnancy test or known pregnancy. If a pregnancy test is positive, then obstetrical CPT codes are indicated. **(General Guidelines (PV-1.0)**).

Hysteroscopically Placed Tubal Occlusion Device (PV-10.2)

PV.ID.0010.2.A

v2.0.2026

- TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76856 or CPT® 76857) is medically necessary if:
  - Suspected complication of hysteroscopically placed tubal occlusion device:
    - Abnormal tubal occlusion device position
    - Uterine perforation
    - Severe pain
    - Excessive bleeding

Proprietary Information of UnitedHealthcare.

Implantable Contraceptive Devices (PV-10.3)

PV.ID.0010.3.A
v2.0.2026

- If implant is unable to be palpated
  - If implant is radiopaque (contains barium sulphate)
    - Initial imaging should include either Ultrasound or X-ray of arm
    - If thoracic implant migration is suspected Chest X-ray should be considered
    - If Chest X-ray is equivocal CT Chest without or with contrast (CPT® 71250 or CPT® 71260) or CTA Chest (CPT® 71275) is medically necessary
  - If implant is radiolucent
    - Initial imaging should include Ultrasound of the arm
    - MRI Upper Extremity without contrast (CPT® 73218) is medically necessary if ultrasound is equivocal
    - If thoracic implant migration is suspected MRI Chest without or without and with contrast (CPT® 71550 or CPT® 71552) is medically necessary

Background and Supporting Information

- As of 2019, neither the Essure nor the Adiana tubal occlusion device is in production.
- Currently the only implant available in the United States is an etonogesterl containing implant. The original version of this implant (Implanon) was released in 2001. This was replaced by an updated implant in 2011 (Nexplanon) which contains barium sulphate, making it radiopaque and easily visualized on X-ray.
- A rare complication of the implant is distant vascular migration to the pulmonary vasculature.

Evidence Discussion (PV-10)

- Transabdominal and transvaginal ultrasounds are the initial imaging methods for locating a malpositioned IUD[12,14,11,5,2,3]. Ultrasound has the benefits of being widely available, accurate, and free from exposure to ionizing radiation. The addition of 3D image processing to ultrasound is advantageous as it allows for the visualization of the complete IUD, including the shaft and arms, and demonstrates its relationship to the endometrial cavity[8,2,3].
- In cases where the ultrasound is non-diagnostic and the pregnancy test is negative, an X-ray should be performed. X-rays are useful as IUDs are radiopaque; if the IUD is not visualized on an X-ray, a diagnosis of expulsion can be made[11].

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- If both ultrasound and X-ray results are equivocal, CT or MRI may be useful to delineate the IUD's position and its relationship to other abdominal organs[1,6].

Pelvic Pain/Dyspareunia, Female (PV-11.1)

PV.PD.0011.1.U
v2.0.2026

- This guideline is intended for the workup of pelvic pain in relation to the female pelvic organs
  - If there is clinical concern for a non-gynecological cause of pelvic pain please see the most applicable condition-specific guideline (e.g., General Abdomen, General, General Peripheral Vascular Disease, General Nerve and Neuromuscular Disorder Imaging, etc.)
  - History, physical examination, and laboratory data can guide subsequent workup in individuals presenting with pelvic pain.
    - A pregnancy test should be performed in premenopausal females
  - Ultrasound is the initial work up for pelvic pain suspected to originate from the female pelvic organs
    - Premenopausal pelvic pain and the pregnancy test is positive,
      - See the applicable obstetrical imaging policy
    - Premenopausal pelvic pain and the pregnancy test is negative or the patient is postmenopausal
      - Ultrasound – transvaginal (CPT® 76830) and/or pelvic (CPT® 76856 or CPT® 76857)
      - Duplex Doppler (CPT® 93975 or CPT® 93976) is medically necessary if there is an ovarian mass and/or suspicion of ovarian torsion on the initial ultrasound.
      - Duplex Doppler (CPT® 93975 or CPT® 93976) is medically necessary for chronic pelvic pain (pelvic pain for 6 months or greater)
  - If ultrasound is indicative of pelvic organ disease, etc.)
    - Further imaging as per appropriate section of guidelines (i.e.-ovarian mass/ torsion **Adnexal Mass/Ovarian Cysts (PV-5)**, **Pelvic Inflammatory Disease (PV-7.1)**, etc.)
  - If initial ultrasound is normal
    - Further evaluation depending on the clinical suspicion may include urological work-up, gastroenterology work-up, laparoscopic evaluation(s)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- If the initial ultrasound is equivocal for unexplained chronic pelvic pain (pelvic pain for 6 months or greater) and/or above evaluations are non-diagnostic the following is medically necessary:
  - CT Pelvis with contrast (CPT® 72193) OR
  - MRI Pelvis without contrast or with and without contrast (CPT® 72195 or CPT® 72197)

- Dysmenorrhea
  - Primary Dysmenorrhea
    - Empiric treatment with Nonsteroidal Anti-inflammatories, Hormonal Therapies or non-pharmacologic strategies
    - If failure of empiric treatment – Secondary Dysmenorrhea should be suspected
  - Secondary Dysmenorrhea
    - Initial evaluation is with Ultrasound – transvaginal (CPT® 76830) and/or pelvic (CPT® 76856 or CPT® 76857)
    - Additional work up depends on the pelvic pathology suspected
    - For suspected **Endometriosis (PV-6)**
    - For suspected **Adenomyosis (PV-4)**
    - For suspected **Fibroids (PV-12)**
- Evaluation for Pelvic Adhesive Disease
  - Initial imaging is an Abdominal (CPT® 76700 or CPT® 76705) and/or Pelvic Ultrasound (CPT® 76856 or CPT® 76857) to complete assessment for surgical planning
    - If ultrasound is inconclusive then MRI Pelvis without contrast or with and without contrast (CPT® 72195 or CPT® 72197) is medically necessary for surgical planning
- Persistent Genital Arousal Disorder/Genito-Pelvic Dysesthesia (PGAD/GPD)
  - Work-up should include detailed history, physical exam, and appropriate laboratory exams and neurogenital testing
  - Further work-up is dependent on the suspected etiology
    - For Urethral Diverticula – See **Urethral Diverticula (PV-13.2)**
    - For pelvic floor dysfunction – See **Urinary Incontinence/Pelvis Prolapse/ Fecal Incontinence (PV-22)**
    - For Tarlov Cyst – See **Miscellaneous Spinal Lesions (SP 2.8)**
    - For Pudendal Neuropathy – See **Focal Neuropathy (PN-2.1)**
    - For Pelvic Congestion Syndrome – See **Pelvic Congestion Syndrome (PVD-13.4)**

Proprietary Information of UnitedHealthcare.

- Work-up of interstitial cystitis/bladder pain syndrome (IC/BPS) should include history, physical exam, laboratory exam (urinalysis and urine culture), cystoscopy, and measurement of post void residual urine by bladder catheterization.
  - Pelvic ultrasound (CPT® 76856 or CPT® 76857) and/or TV ultrasound (CPT® 76830) is then medically necessary.
    - CT Pelvis with contrast (CPT® 72193) is medically necessary if ultrasound is equivocal for complicated interstitial cystitis/bladder pain syndrome.
- Proctalgia Syndromes
  - Prior to advanced imaging, the evaluation of rectal/perineal pain should include:
    - Digital rectal examination (assess for mass, fissures, hemorrhoids, etc.)
    - Pelvic examination in females to exclude PID
    - Recent flexible sigmoidoscopy or colonoscopy subsequent to the start of reported symptoms to exclude inflammatory conditions or malignancy.
    - Endoanal ultrasound (CPT® 76872), MRI Pelvis with and without contrast (CPT® 72197), or CT Pelvis with contrast (CPT® 72193) are medically necessary after the above studies have been performed or if laboratory or clinical information suggest infection, abscess, or inflammation
- MRI (MRI Pelvis without contrast CPT® 72195) for Defecography is considered investigational/experimental by UHC.

Background and Supporting Information

- Dysmenorrhea is pain with the menstrual cycle. It can be divided into primary dysmenorrhea (pain in the absence of pelvic pathology) and secondary dysmenorrhea (pain due to pelvic pathology or recognized medical condition).
- Multiple meta-analyses have been performed regarding the detection of intra-abdominal adhesions by various imaging modalities. Limperg et al found that ultrasound has a sensitivity of 95.9%, specificity of 93.1%, a PPV of 60.4% and a NPV of 99.2% for the identification for assessment of periumbilical bowel adhesion. In addition, Gerner-Rasmussen found an overall accuracy for detecting intra-abdominal adhesions of 76-100% for ultrasound, 79-90% for MRI and 66% for CT. Ultrasound has the benefit of being widely available and lacks exposure to contrast agents. MRI is able to visualize adhesions between viscera, but has a higher false positive rate and over diagnoses adhesions.
- Interstitial Cystitis/Bladder Pain Syndrome (IC/BPS) has an unpleasant sensation (pain, pressure, discomfort), perceived to be related to the urinary bladder. It is associated with lower urinary tract symptoms of more than six weeks duration, in the absence of infection or other identifiable causes.
- Proctalgia syndromes are characterized by recurrent episodes of rectal/perineal pain, and may be due to sustained contractions of the pelvic floor musculature.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Evidence Discussion (PV-11)

- Transabdominal pelvic and/or transvaginal pelvic ultrasound are widely accepted as the initial imaging modality of choice for pelvic pain of gynecologic origin[3,9,10,11]. Ultrasound also allows for real-time evaluation with color and power Doppler which can help identify vascular flow and distinguish fluid and cysts from soft tissue[9,10,11]. Additional benefits to ultrasound as a first line imaging modality include wide availability, fast access, and lack of ionizing radiation exposure.
- MRI is accepted as an adjunct modality to ultrasound in cases where ultrasound may not fully characterize a soft tissue abnormality due to its superior signal to noise ratio[9,10,11].

  CT of the pelvis may demonstrate engorged veins, pelvic fulid, peritoneal thickening, hydrosalpinx or pyosalpinx and tubo-ovarian abscess[9,10].
- MRI pelvis, CT pelvis or endoanal ultrasound are appropriate for the evaluation of proctalgia after digital rectal examination, pelvic examination in females and recent endoscopy to exclude inflammatory conditions or malignancy[4].
- Often, the history, physical examination, and laboratory data can guide subsequent workup in individuals presenting with pelvic pain. If initial ultrasound is normal, further evaluation may include urological work-up, gastroenterology work-up, or laparoscopic evaluation(s)[7].
  - The differential diagnosis for chronic pelvic pain is extensive. Determining the etiology of pelvic pain is important to plan treatment[5,6,7].

Suspected Uterine Mass (PV-12.0)

PV.UF.0012.1.A
v2.0.2026

- A potential mass found on exam and/or found incidentally on other imaging
  - Transvaginal (TV) ultrasound imaging (CPT® 76830) is the medically necessary initial study
    - Pelvic ultrasound (CPT® 76856 or CPT® 76857) is medically necessary if requested as a complimentary study to the TV ultrasound
  - Further imaging as per appropriate section of guidelines (i.e., ovarian mass/torsion **Adnexal Mass/Ovarian Cysts (PV-5)**, **Adenomyosis (PV-4.1)**, etc.)

Proprietary Information of UnitedHealthcare.

Leiomyoma/Uterine Fibroids (PV-12.1)

PV.UF.0012.1.A
v2.0.2026

Leiomyomata are also known as “fibroids.”

- Pelvic ultrasound (CPT® 76856 or CPT® 76857) and/or TV ultrasound (CPT® 76830) are medically necessary for any of the following:
  - Suspected leiomyoma with symptoms of pelvic pain, suspected ureteral obstruction secondary to inability to void urine, pelvic pressure and/or abnormal uterine bleeding and/or an enlarged uterus found on physical exam with a negative pregnancy test (if pre-menopausal).
  - Pre-operative prior to myomectomy
  - Recurrent symptoms such as abnormal bleeding, pain, or pelvic pressure
  - 3-D Rendering (CPT® 76377 or CPT® 76376) and/or Duplex (Doppler) scan (CPT® 93975 complete; CPT® 93976 limited) if ultrasound is equivocal and intracavitary lesion is suspected, or for surgical planning for myomectomy
  - There is no current evidence to support 3-D Rendering (CPT® 76377 or CPT® 76376) for planning for uterine artery embolization.
- MRI Pelvis and/or Abdomen to determine surgical approach for hysterectomy is not medically necessary.
- MRI Pelvis without and with contrast (CPT® 72197), or without contrast (CPT® 72195) in the evaluation of leiomyomas is medically necessary for the following:
  - Guide the treatment of leiomyoma/fibroid in an enlarged uterus with multiple leiomyoma/fibroid following indeterminate ultrasound when myomectomy is planned.
  - Equivocal sonohysterography or panoramic hysteroscopy with suspected submucous leiomyoma and imaging is needed to plan for myomectomy
  - Leiomyoma necrosis is suspected
  - Guide the treatment of leiomyoma/fibroid in an enlarged uterus with multiple leiomyoma/fibroid following indeterminate ultrasound when Radiofrequency Ablation of Leiomyomas is planned
  - Uterine artery embolization is being considered
    - If MRI is equivocal, MRA Pelvis (CPT® 72198) or CTA Pelvis (CPT® 72191) if requested by or in consultation with the interventional radiologist planning the uterine artery embolization
    - There is no evidence to support interval MRI after embolization unless persistent or recurrent symptoms

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

        - The vascular embolization code (CPT® 37243) is inclusive of all radiological supervision and interpretation, intraprocedural roadmapping, and imaging guidance necessary to complete the intervention.
            - Additional advanced imaging codes are not medically necessary during the procedure to complete the intervention.
- If malignancy is suspected, See **Oncology Imaging Guidelines**.
    - MRI Pelvis with and without (CPT® 72197) for suspected leiomyosarcoma is medically necessary if one or more of the following ultrasound features AND symptoms are present;
        - Ultrasound features suggestive of leiomyosarcoma are:
            - Large sized (greater than 8 cm)
            - Irregular borders
            - Areas of cystic change or necrosis
            - Increase in central and peripheral vascularity
            - Rapid change in size
        - Symptoms suggestive of leiomyosarcoma would include postmenopausal woman with an new or rapidly enlarging myometrial mass or rapid growth of a uterine mass in a premenopausal patient (increase of 6 weeks gestation size within 1 year)
- CT is not medically necessary for evaluating female pelvic anatomy due to its limited soft tissue contrast resolution

Evidence Discussion (PV-12)

- Transabdominal pelvic and/or transvaginal pelvic ultrasound are widely accepted as the initial imaging modality of choice for uterine fibroids[1,2]. Ultrasound also allows for real-time evaluation with color and power Doppler which can help identify vascular flow and distinguish fluid and cysts from soft tissue. 3-D rendering is useful for further evaluation of intracavitary lesions and for surgical planning for myomectomy[3]. Additional benefits to ultrasound as a first line imaging modality include wide availability, fast access, and lack of ionizing radiation exposure.
- MRI is accepted as an adjunct modality to ultrasound in cases where ultrasound may not fully characterize a soft tissue abnormality due to its superior signal to noise ratio. MRI can be useful for surgical planning for myomectomy, determining degeneration or necrosis of fibroids, and to plan uterine artery embolization or radiofrequency ablation[4,5,7,9].
- MRI may be considered for suspected leiomyosarcoma in cases where ultrasound features and symptoms are suggestive of this diagnosis[8]. The reported prevalence of unsuspected sarcoma at surgery for symptomatic leiomyoma ranges widely, from 0.01% (one in 10 000) to 0.28% (one in 352)[8].

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- MRI offers the highest accuracy for characterization of uterine masses before intervention due to improved soft-tissue contrast, larger field of view, diffusion sequences, and multiplanar sequences. For procedural planning, MRI offers better localization of fibroid position in the uterus and can be used to assess viability and arterial supply of fibroids. In the context of preprocedural planning, MRI features have been evaluated for performance in separating leiomyosarcoma from leiomyomas or atypical leiomyomas. MRI features noted in multiple studies as associated with leiomyosarcoma include the following features: intermediate to high signal intensity of the mass at T2-weighted imaging, irregular margins of the uterine mass with the adjacent myometrium, and high signal intensity at high–b value diffusion-weighted imaging and corresponding low signal intensity on apparent diffusion coefficient maps[8].
- MRA or CTA may be used to determine vascular flow to uterine fibroids for embolization planning in cases where MRI is insufficient. Knowledge of the vascular supply for fibroids is crucial for successful embolization of target arteries[11].
- CT is of limited use in the evaluation of pelvic anatomy due to its limited soft tissue contrast resolution[10].

Endometrial Polyp (PV-12.2)

PV.UF.0012.1.A

v2.0.2026

- Transvaginal (TV) ultrasound imaging (CPT® 76830) is the medically necessary initial study
  - Pelvic ultrasound (CPT® 76856 or CPT® 76857) is medically necessary if requested as a complimentary study to the TV ultrasound
  - 3-D Rendering (CPT® 76377 or CPT® 76376) is medically necessary for further delineation of the intracavitary lesion
- Hysteroscopy remains the gold standard for diagnosis and treatment of endometrial polyps
  - Allows for direct visualization, histologic diagnosis and concurrent treatment of the polyp
  - If biopsy confirms a malignancy, then see the appropriate oncology guideline

Asymptomatic Thickened Endometrium (PV-12.3)

PV.UF.0012.1.A
v2.0.2026

- Thickened endometrium (>4mm) incidentally discovered in a postmenopausal individual without bleeding
  - Need not routinely trigger evaluation, but individualized assessment, including endometrial sampling, based on patients risk factors is medically necessary
    - If biopsy confirms a malignancy, then see the appropriate oncology guideline
    - Advanced imaging is not medically necessary for Endometrial Intraepithelial Neoplasia or Atypical Endometrial Hyperplasia (EIN-AEH) as imaging has not been found to improve outcomes for this condition.

Vaginal Masses (PV-13.3)

PV.UD.0013.3.A
v2.0.2026

- Pelvic ultrasound (CPT® 76856 or CPT® 76857) and/or Transvaginal ultrasound (CPT® 76830) and/or Transperineal ultrasound (CPT® 76872) is medically necessary for initial evaluation
- MRI Pelvis without and with contrast (CPT® 72197) is medically necessary for surgical planning

Background and Supporting Information

Symptomatic infection of congenital periurethral glands can result in urethral diverticula. Symptoms include pain, urinary urgency, frequency of urination, recurrent urinary tract infection, dribbling after urination, or incontinence.

Evidence Discussion (PV-13)

- Transabdominal, transvaginal and transperineal ultrasound are often utilized as initial imaging for female pelvic anatomy[5,6,10,11]. Ultrasound has the benefit of being widely available, accurate and does not have exposure to ionizing radiation. MRI is useful in cases of equivocal ultrasound imaging or for surgical planning[5,6,11].
- Multiple modalities can be used for the detection of urethral diverticula. Transperineal and transvaginal ultrasound can be utilized in detecting urethral diverticula. Ultrasound has the advantage of being readily available, does not require catheterization and lacks exposure to ionizing radiation. However ultrasound is operator dependent and the reported sensitivity for detection of urethral diverticula ranges from <50 to 100%[4]. Urethrography can also be used to detect urethral diverticula with a sensitivity of 67-95% but carries the risk of radiation exposure[4]. MRI has excellent soft tissue resolution and has a reported sensitivity of 100% for urethral diverticula[2].

Uterine Anomalies (PV-14.1)

PV.UA.0014.1.A
v2.0.2026

- This guideline is intended for congenital uterine anomalies.
- Pelvic ultrasound (CPT® 76856 or CPT® 76857) and/or TV ultrasound (CPT® 76830) is medically necessary for initial evaluation. 3-D Rendering (CPT® 76377 or CPT® 76376) may be an add-on if uterine anomaly is suspected on ultrasound.
- If ultrasound is indeterminate:
  - Sonohysterosalpingography (CPT® 76831) is medically necessary
- Retroperitoneal ultrasound (CPT® 76770 or CPT® 76775) is medically necessary to evaluate for possible coexisting renal anomalies if a complex uterine anomaly is present.
  - MRI Abdomen without contrast or without and with contrast (CPT® 74181 or CPT® 74183) or CT urography (CT Abdomen and Pelvis without and with contrast CPT® 74178) is medically necessary for indeterminate renal anomaly on ultrasound.
- An arcuate uterus is considered a normal variant. Therefore, advanced imaging of a known arcuate uterus is not medically necessary.
- MRI Pelvis without and with contrast (CPT® 72197) is medically necessary when:
  - Ultrasound is indeterminate for a complex uterine anomaly, or
  - Requested for surgical planning of previously diagnosed uterine anomaly
    - If ultrasound confirms uterine septum, advanced imaging is not indicated for surgical planning

Background and Supporting Information

Mullerian anomalies are complex structural anomalies deriving from errors in the embryonic development of the mullerian duct. These may include uterine remnant or agenesis, cervical agenesis, unicornate utereus, bicornuate uterus, uterine didelphys, vaginal septum and/or other complex anomalies. Uterine septum is not a complex uterine anomaly.

Click Here to Return to the Main TOC

Vaginal Anomalies (PV-14.2)

PV.UA.0014.2.A
v2.0.2026

- This guideline is intended for congenital vaginal anomalies.
- Pelvic ultrasound (CPT® 76856 or CPT® 76857) and/or TV ultrasound (CPT® 76830) and/or Transperineal ultrasound (CPT® 76872) and/or Translabial ultrasound (CPT® 76857) are medically necessary for initial evaluation. 3-D Rendering (CPT® 76377 or CPT® 76376) is medically necessary as an add-on if vaginal anomaly is suspected on ultrasound.
- MRI Pelvis without and with contrast (CPT® 72197) is medically necessary when:
  - Ultrasound is indeterminate for a complex vaginal anomaly, or
  - Requested for surgical planning of previously diagnosed vaginal anomaly

Background and Supporting Information

- Mullerian anomalies are complex structural anomalies deriving from errors in the embryonic development of the mullerian duct. These may include uterine remnant or agenesis, cervical agenesis, unicornate utereus, bicornuate uterus, uterine didelphys, vaginal septum and/or other complex anomalies. Uterine septum is not a complex uterine anomaly.

Evidence Discussion (PV-14)

- Transabdominal and transvaginal ultrasound remain the preferred initial imaging for female pelvic anatomy[1]. Ultrasound has the benefit of being widely available, accurate and does not have exposure to ionizing radiation, making it an excellent first line modality for the evaluation of Müllerian anomalies. With the addition of 3D imaging, ultrasound has a reported sensitivity as high as 100% for the detection of uterine anomalies[2]. MRI is also highly sensitive for the detection of uterine anomalies and is useful in cases of equivocal ultrasound imaging or for surgical planning of known complex malformations[2].
- For detection of congenital anomalies of the kidney and upper urinary tract ultrasound is usually the first line imaging modality because of its wide availability, low cost and lack of ionizing radiation[6,7]. CT or MRI can be utilized for further delineation of the renal anatomy in cases where ultrasound is inconclusive.

Fetal MRI (PV-15.1)

PV.MR.0015.1.A
v2.0.2026

CPT® Code Guidance
• Fetal MRI (CPT® 74712) [plus CPT® 74713 for each additional fetus]
• Do not report CPT® 74712 and CPT® 74713 in conjunction with CPT® 72195, CPT® 72196, CPT® 72197
• If only placenta or maternal pelvis is imaged without fetal imaging, use MRI Pelvis (CPT® 72195)

Indications for Fetal MRI

- Fetal MRI (CPT® 74712) [plus CPT® 74713 for each additional fetus] optimally performed after 18 to 22 weeks gestation, is medically necessary for assessment of known or suspected fetal abnormalities for counseling, surgical, or delivery planning.
  - There are cases when surgical planning may necessitate imaging earlier than 18 weeks. For those cases where surgery is to be performed prior to 18 weeks and they otherwise meet indications for imaging per this criteria, Fetal MRI may be approved.
- 3D-4D (CPT® 76376 or CPT® 76377) rendering can be added for surgical planning with diagnosis of complex CHD in the fetus or for surgical planning of other complex fetal malformations
- Repeat fetal MRI (CPT® 74712) [plus CPT® 74713 for each additional fetus] is medically necessary later in pregnancy for:
  - Delivery or perinatal surgical planning
- Fetal MRI indications include but may not be limited to the following:
  - Brain
    - Congenital anomalies
      - Ventriculomegaly
      - Agenesis of the corpus callosum
      - Abnormalities of the cavum septum pellucidum
      - Holoprosencephaly
      - Posterior fossa anomalies
      - Malformations of cerebral cortical development
      - Microcephaly
      - Solid or cystic masses
      - Cephalocele

PV.MR.0015.4.A

v2.0.2026

- Pelvimetry (CT or MRI Pelvimetry) lacks sufficient evidence to be clinically useful. Current recommendations are that further randomized control studies be performed before it is adapted into routine clinical practice.

Evidence Discussion (PV-15)

- Transabdominal and transvaginal obstetric ultrasound remain the preferred initial imaging for fetal evaluation of the fetus and maternal pelvic anatomy[1]. Ultrasound has the benefit of being widely available and does not have exposure to ionizing radiation.
- Fetal MRI has emerged as an adjunct imaging to fetal ultrasound in cases where the initial ultrasound is unclear or additional information is needed for surgical or delivery planning. It has the benefits of not being limited by maternal body habitus, fetal position, ossification of fetal skull/bones, or oligohydramnios[1].
- There is much uncertainty surrounding the use of gadolinium in pregnancy. Gadolinium is water-soluble and can cross the placenta, reaching the amniotic fluid and fetal circulation. While the risk of fetal effects of gadolinium remains uncertain, it has been shown to be teratogenic in animal studies. Given these possible fetal risks, the use of gadolinium in pregnancy should be limited. Its use should only be in situations where the benefits clearly outweigh the risks[8].
- MRI can be used as an adjunct to ultrasound if there is suspicion for abnormal placentation. Sensitivity and specificity for placental invasion is comparable between ultrasound and MRI (sensitivity of 88% and sensitivity of 86% for ultrasound and 93% and 94% for MRI)[14]. MRI has also been associated with both false positive and false negative diagnoses. Hence, a stepwise approach to evaluation, starting with ultrasound, then followed by the use of MRI for equivocal or nondiagnostic ultrasound is supported.
- Ectopic pregnancy is the leading cause of maternal mortality in the first trimester[9]. Ultrasound remains the initial imaging modality for ectopic pregnancy, but MRI may add additional information, especially in cases of rare implantation-site ectopic pregnancy (e.g. Cesarean Section scar ectopic). MRI is indicated in cases where the ultrasound is nondiagnostic[9].
- There is currently insufficient evidence to support the use of imaging pelvimetry (x-ray, CT or MRI) in delivery planning[11].

Abnormal Non-Invasive Prenatal Testing (NIPT) and Maternal Malignancy (PV-15.5)

PV.MR.0015.4.A

v2.0.2026

- Non-invasive Prenatal Testing (NIPT) is a common screening method to assess the risk of fetal aneuploidy in the antenatal period. Cell-free DNA (cfDNA) of placental origin circulating in the maternal blood is tested, typically by chromosome microarray analysis, for certain aneuploidies. The presence of genomic anomalies originating from a maternal source can confound these results and have also been linked to occult maternal malignancy.
- When found, maternally derived anomalies merit further work up.
  - Complete work up to rule out fetal source of anomalous results should be performed.
    - This would include further testing such as detailed fetal anatomy scan, amniocentesis or chorionic villus sampling (CVS) if applicable.
  - A targeted maternal work-up should be performed.
    - Complete history, physical and appropriate lab work up (i.e. CBC, peripheral smear, LDH, Liver and renal function testing, appropriate tumor markers) should be performed to better elucidate possible malignant source.
      - If clinical work up reveals a suspected source, targeted imaging depending on suspected source (i.e. mammogram, chest x-ray, liver ultrasound) should be undertaken
      - If clinical work up does not reveal potential source
        - Whole Body MRI (CPT® 76498) is medically necessary

Background and Supporting Information

Studies have show that the most common cancers found among those with abnormal NIPT were of hematologic origin, followed by breast and colon cancers.

Some tumor markers are less reliable in pregnancy. CA 125, CA 15.3, AFP and SCC Ag can be elevated in normal pregnancy. However, CA19-9, LDH, AMH, CEA and HE-4 are not commonly elevated in pregnancy. These tumor markers can aid in focusing clinical work up. NIPT is typically performed in the first and the early second trimesters. This is prior to physiologic elevation of inhibin B in the third trimester and development of

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

hypertensive abnormalities of pregnancy (which can increase LDH), so these markers may be considered in early pregnancy.

Evidence Discussion (PV 15.5)

No prospective large-scale studies have evaluated NIPT and incidental detection on maternal malignancy, hence the specificity and sensitivity of this testing remains unknown. However, a series of retrospective studies report a positive predictive value of NIPT for detection of occult maternal malignancy of over 50%. There are currently no evidence-based guidelines by which to classify a NIPT result as suspicious for malignancy[1,2,3,4,5].

If initial work up determines a maternal source of the abnormal NIPT, targeted maternal work up is merited. If targeted work up fails to reveal possible source of abnormal NIPT then additional screening is merited[5,6]. Whole body MRI is preferred in pregnancy as it yields the highest diagnostic benefit. MRI also lacks ionizing radiation, making a preferred imaging modality to CT or PET. Gadolinium should be avoided during pregnancy secondary to possible risk to the fetus[7,8,9]. MRI, however, is susceptible to artifact and may not be achievable by pregnant patients, who may not be able to breath hold and lay supine for long durations[10,11].

Molar Pregnancy and GTN (PV-16.1)

PV.MP.0016.1.A
v2.0.2026

- Molar pregnancy –
  - Ultrasound is the initial medically necessary study
  - Once diagnosed on an Obstetrical Ultrasound treatment is usually evacuation.
- Individuals should undergo chest x-ray pre- and post-evacuation.
  - If chest x-ray is positive for metastases, management as per GTN guidelines, see **Gestational Trophoblastic Neoplasia (GTN) (ONC-22.5)** in the Oncology Imaging Guidelines.
- Serum hCG levels are obtained every 1-2 weeks after treatment of molar pregnancy until they normalize
- Individuals with a molar pregnancy and rising or plateauing hCG levels post evacuation and/or Gestational trophoblastic neoplasia
  - See **Gestational Trophoblastic Neoplasia (GTN) (ONC-22.5)** in the Oncology Imaging Guidelines.

Impotence/Erectile Dysfunction (PV-17.1)

PV.ED.0017.1.A
v2.0.2026

- Imaging depends on the suspected disease and is medically necessary as follows:
  - Penile Doppler ultrasound (CPT® 93980) if erectile dysfunction suspected[2]
  - CTA Pelvis with contrast (CPT® 72191) if large vessel vascular insufficiency is suspected following ultrasound.
  - Duplex ultrasound (CPT® 93980) to assess penile vasculature in Peyronie's disease[1]
  - If male hypogonadism is suspected, See **Pituitary (HD-19)** in the Head Imaging Guidelines
- Functional MRI or PET studies are not medically necessary for this indication.
- Priapism
  - Penile Doppler Ultrasound (CPT® 93980) is medically necessary if non-ishemic priapism is suspected
  - MRI likely does not have a role in the initial diagnosis of priapism given the time sensitive nature of diagnosis and management
  - In patients with persistent non-ischemic priapism where an embolization may be necessary CTA (CPT® 72191) or MRA Pelvis (CPT® 72198) is medically necessary
  - Penial Doppler Ultrasound (CPT® 93980) is medically necessary post procedure for ischemic priapism
  - If patient has priapism >24-48 hours or refractory to treatment, MRI Pelvis without and with contrast (CPT® 72197) or MRI Pelvis without contrast (CPT® 72195) is medically necessary

Evidence Discussion (PV-17)

- Erectile dysfunction (ED) may utilize penile Doppler ultrasound to assess penile vasculature. Ultrasound has the advantages of being able to provide robust information about both cavernous arterial inflow and the veno-occlusive capacity of the penis[7], is readily available, minimally invasive and tolerated well by patients[8]. Advanced imaging with CTA of the pelvis with contrast may be indicated if large vessel vascular insufficiency is suspected. A penile duplex ultrasound may be utilized in the workup of Peyronie's disease[1].
- Advanced imaging for ED or Peyronie's disease with either PET or functional MRI is considered investigational.
- A penile Doppler ultrasound may be utilized for workup of non-ischemic priapism or post procedure for ischemic priapism[5]. The sensitivity of Doppler ultrasound in localizing an anterior-cavernosal fistula is approximately 100%[4]. If embolization is planned, CTA or MRA of the pelvis may be indicated.

Penis-Soft Tissue Mass (PV-18.1)

PV.PM.0018.1.A
v2.0.2026

- Penile ultrasound (CPT® 76857) is medically necessary for initial evaluation soft-tissue lesions of the penis, Duplex (Doppler) scan CPT® 93975 complete; CPT® 93976 limited) is medically necessary as an add-on.
- If primary penile cancer is suspected, biopsy is indicated
  - For further workup of biopsy confirmed penile cancer see **Cancers of External Genitalia – Initial Work-up/Staging (ONC-24.6)** in the Oncology Imaging Guidelines.
- Peyronie's Disease
  - Ultrasound (CPT® 76857) is medically necessary
  - MRI Pelvis without and with contrast (CPT® 72197) is medically necessary if ultrasound is equivocal and surgery or injection therapy is being contemplated

Evidence Discussion (PV-18)

- Soft tissue lesions of the penis can be evaluated with penile ultrasound with doppler imaging as an initial evaluation[1]. Ultrasound allows a readily available, non-invasive option for accurate assessment of the vascular and structural features of the penis while avoiding ionizing radiation. Advanced imaging with CT abdomen and pelvis and/or lymphoscintigraphy or SPECT/CT may be indicated for biopsy proven cancer depending on the stage, however is not necessary for the initial workup of a penile mass[2].
- Peyronie's disease can be initially assessed utilizing ultrasonography[5]. Advanced imaging with MR can be performed after equivocal ultrasound if necessary prior to surgical intervention or injection therapy[6].

Male Pelvic Disorders (PV-19.1)

PV.PE.0019.1.U
v2.0.2026

- This guideline is intended for the workup of pelvic pain in relation to the male pelvic organs
  - If there is clinical concern for a non-genitourinary cause of pelvic pain please see the most applicable condition-specific guideline (e.g., General Abdomen, General, General Peripheral Vascular Disease, General Nerve and Neuromuscular Disorder Imaging, etc.)
- Chronic Pelvic Pain Syndrome (CPPS)
  - This may include males experiencing chronic perineal pain, bilateral scrotal content pain, penile pain, pelvic pain or pain with ejaculation. See: **Scrotal Pathology (PV 20.1)** for evaluation of scrotal pain as predominant symptom.
  - Workup includes comprehensive history, physical exam, and laboratory studies as well as cystoscopy, urodynamics, and/or imaging when the diagnosis is unclear
    - Transabdominal pelvic ultrasound (bladder and prostate [CPT® 76856 or CPT® 76857]) is medically necessary as initial imaging
    - CT Pelvis with contrast (CPT® 72193) OR MRI Pelvis without contrast (CPT® 72195) OR with and without contrast (CPT® 72197) is medically necessary if ultrasound is equivocal or nondiagnostic and alternative clinical conditions are being considered
- Prostate
  - Prostate Disorders
    - Suspected Benign Prostatic Hypertrophy with obstructive voiding symptoms:
      - Transrectal ultrasound (CPT® 76872) or Pelvis transabdominal ultrasound (bladder and prostate [CPT® 76856 or CPT® 76857]) is medically necessary.
    - For prostatitis with urinary retention or suspected abscess any of the following imaging studies are medically necessary:
      - Transrectal ultrasound (CPT® 76872) or Pelvis transabdominal ultrasound (bladder and prostate [CPT® 76856 or CPT® 76857])
      - CT Pelvis with contrast (CPT® 72193) or MRI Pelvis without contrast (CPT® 72195) or with and without contrast (CPT® 72197) if ultrasound is equivocal for abscess or mass
  - Prostate Artery Embolization (PAE)
    - MRA Pelvis (CPT® 72198) or CTA Pelvis (CPT® 72191) is medically necessary for evaluation of the pelvic vasculature if:
      - prostate artery embolization is planned

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

        - The vascular embolization code (CPT® 37243) is inclusive of all radiological supervision and interpretation, intraprocedural roadmapping, and imaging guidance necessary to complete the intervention.
            - Additional advanced imaging codes are not medically necessary during the procedure to complete the intervention.
- Testicular
    - Hematospermia
        - MRI Pelvis without contrast (CPT® 72195) or MRI Pelvis without and with contrast (CPT® 72197) is medically necessary to evaluate for ANY of the following:
            - Age 40 or older
            - Recurrent hematospermia, regardless of age
            - Hematospermia with associated signs or symptoms of disease (e.g., pain, fever, leukocytosis, hematuria), regardless of age
            - Abnormal findings on Transrectal ultrasound
        - Imaging evaluation is not medically necessary for individuals under age 40, with a transient hematospermia episode without associated signs or symptoms of disease.
- Rectal
    - Proctalgia Syndromes
        - Prior to advanced imaging, the evaluation of rectal/perineal pain should include:
            - Digital rectal examination (assess for mass, prostate, fissures, hemorrhoids, etc.)
            - Recent flexible sigmoidoscopy or colonoscopy subsequent to the start of reported symptoms to exclude inflammatory conditions or malignancy
        - Endoanal ultrasound (CPT® 76872), MRI Pelvis without and with contrast (CPT® 72197), or CT Pelvis with contrast (CPT® 72193)is medically necessary after the above studies have been performed or if laboratory or clinical information suggest infection, abscess, or inflammation
    - MRI (MRI Pelvis without contrast CPT® 72195) for Defecography is considered investigational/experimental by UHC
- Bladder
    - Work-up of interstitial cystitis/bladder pain syndrome (IC/BPS) may include history, physical exam, laboratory exam (urinalysis and urine culture), cystoscopy, and measurement of post void residual urine by bladder catheterization
        - Pelvic ultrasound (CPT® 76856 or CPT® 76857) is medically necessary
            - CT Pelvis with contrast (CPT® 72193) is medically necessary if ultrasound is equivocal for complicated interstitial cystitis/bladder pain syndrome

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Background and Supporting Information

- The proctalgia syndromes are characterized by recurrent episodes of rectal/perineal pain, and may be due to sustained contractions of the pelvic floor musculature.

Evidence Discussion (PV-19)

- For individuals with lower urinary tract symptoms suspected to be caused by Benign Prostatic Hypertrophy ultrasound is the modality of choice for evaluation. It allows for assessment of bladder volume and post-void residual as well as intravesical prostatic protrusion[6]. Ultrasound is advantageous as it is readily available, effective, and free of ionizing radiation.
- Prostate Artery Embolization is an excepted treatment for the management of lower urinary tract symptoms according to the American Urological Association[11]. Imaging is indicated for further delineation of the pelvic vasculature to aid in preprocedure surgical planning. The accuracy of CTA to identify the Prostate artery has been shown to approximately 97%[13]. MRI angiography has been shown to identify the prostate artery in 76% of cases, has been helpful in identifying malignancy when suspected and does not carry the risk of radiation exposure[13].
- Transrectal ultrasound is supported for the initial diagnostic imaging for hematospermia[2]. Ultrasound has high sensitivity for detecting abnormalities of the prostate and seminal tract, demonstrating abnormalities in 82-95% of men with hematospermia[2]. Ultrasound is advantageous as it is readily available, effective, and free of ionizing radiation. It also allows for simultaneous aspiration or biopsy of any lesions detected. MRI is a useful adjunct to ultrasound imaging. CT has limited value in the evaluation of hematospermia due to its limited ability to differentiate structural changes of the prostate and seminal tract and its lack of soft-tissue contrast[2].
- In individuals with suspected Proctalgia initial evaluation should include a through exam, including digital rectal exam and direct visualization with sigmoidoscopy or colonoscopy to exclude other causes of rectal pain. Clinical history and normal digital rectal exam is often sufficient to make a diagnosis of Proctalgia[7]. If infection, abscess or inflammation is suspected imaging is indicated[15].
- The work up for interstitial cystitis/bladder pain syndrome (IC/BPS) should include a careful history, physical and laboratory examination[16]. Additional testing such as radiologic imaging should be undertaken only when it will alter the treatment approach[16]. Ultrasound may be useful for adjunct diagnosis[17] and has the advantages of being widely available and without ionizing radiation. Additional testing with CT may be appropriate when ultrasound results are inconclusive but bears the risk of ionizing radiation.

Scrotal Pathology (PV-20.1)

PV.SP.0020.1.A
v2.0.2026

- Scrotal pain or mass
  - Scrotal ultrasound (CPT® 76870) and/or Duplex (Doppler) ultrasound (CPT® 93975 or CPT® 93976) for initial evaluation
  - MRI Pelvis without and with contrast (CPT® 72197) or Tc-99m scrotal scintigraphy (CPT® 78761) is medically necessary if ultrasound is inconclusive.
- Scrotal pain and hydrocele with suspicion of hernia
  - See Inguinal or Femoral Hernia, or Indeterminate **Groin Pain (AB-12.1)** in the Abdomen guidelines
- Cryptorchidism/undescended testis in the adult.
  - Scrotal ultrasound (CPT 76870), MRI Pelvis without and with contrast (CPT® 72197), or CT Pelvis with contrast (CPT® 72193)
- Variocele evaluation
  - Scrotal ultrasound and/or Duplex (Doppler) ultrasound (CPT® 76870 and/or CPT® 93975 or CPT® 93976) of the scrotum with color flow mapping in supine and upright positions is medically necessary to assess venous reflux into plexus pampiniformis if varicocele suspected (for example, in inguinal hernia evaluation)
  - CT Abdomen and Pelvis with contrast (CPT® 74177) is medically necessary for right-sided varicocele, when there is suspicion for intra-abdominal pathology

Background and Supporting Information

- The causes of scrotal pain may include torsion, epididymitis, strangulated hernia, segmental testicular infarction, trauma, testicular tumor, and idiopathic scrotal edema.[1]

Testicular Microlithiasis (PV-20.3)

PV.SP.0020.3.A

v2.0.2026

- Scrotal ultrasound (CPT® 76870) is medically necessary for initial evaluation
- Annual Scrotal ultrasound (CPT® 76870) follow-up is medically necessary only if a risk factor is present which include:
  - Family history of germ cell tumor
  - Maldescent
  - Orchidopexy
  - Testicular atrophy
- For personal history of germ cell tumor See **Testicular, Ovarian and Extragonadal Germ Cell Tumors (ONC-20)** in the Oncology Imaging Guidelines

Fistula in Ano (PV-21.1)

PV.PA.0021.1.A
v2.0.2026

- MRI Pelvis without and with contrast (CPT® 72197) is medically necessary.
  - If MRI cannot be performed, endoscopic ultrasound is superior, and thus preferential, to CT imaging.
  - CT Pelvis with contrast (CPT® 72193) is an inferior study to either of the above (accuracy of endoscopic ultrasound vs. CT for perianal fistula is 82% vs. 24%) and it is medically necessary only in circumstances in which MRI and endoscopic ultrasound cannot be performed.

Evidence Discussion (PV-21.1)

- Anorectal fistulas most commonly arise from abscesses that originate in the anal crypts (90%). Physical exam will frequently identify these but advanced imaging is often needed to determine the course of the fistulous tract, its relationship with the sphincteric musculature and associated infection/abscess[11]. Because of its superior resolution, MRI is the preferred modality, followed by endoscopic ultrasound and then CT[1].
- Non-iatrogenic anal fistula located in atypical positions (lateral) suggest the possibility of Crohn's disease. See IBD – Perirectal/Perianal disease (AB-23.3).

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Abscess (PV-21.2)

PV.PA.0021.2.A
v2.0.2026

- Perirectal Abscess
  - MRI Pelvis without and with contrast (CPT® 72197) is the preferred study
    - CT Pelvis with contrast (CPT® 72193) is medically necessary as an alternative study if desired.
  - For the evaluation of Perianal and Perirectal Disease related to Crohn's Disease, See **Perirectal/Perianal Disease (AB-23.3**) in the Abdomen Imaging Guidelines.
- Perineal Abscess
  - Fournier Gangrene
    - Diagnosis commonly made on the basis of clinical and physical exam
    - CT Pelvis, contrast as requested, is medically necessary for evaluating extent of disease for surgical planning
- Vulvar Abscess
  - CT Pelvis, contrast as requested, is medically necessary to delineate the extent of a vulvar abscess and evaluate surrounding structures for surgical planning
  - MRI Pelvis without and with contrast (CPT® 72197) may also be medically necessary for surgical planning

Evidence Discussion (PV-21.2)

- Pelvic infections can take the form of intraperitoneal abscesses or perineal wall infections [12].
- Refer to Abdominal Sepsis (AB-3-1) for intraabdominal pelvic abscess.
- History and physical can usually identify perineal (perirectal and perianal) abscesses[12]. Due to a high rate of recurrence due to associated fistulous tracts, advanced imaging with MRI (preferred because of its improved resolution), endorectal ultrasound or CT scan[1,11]. Primary treatment is surgical drainage[1,12].

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Pelvic Fistula (PV-21.3)

PV.PA.0021.3.A
v2.0.2026

- History and physical exam (to include pelvic and/or anorectal examination):
  - Rectovesicular Fistula - the following are medically necessary:
    - MRI Pelvis with and without contrast (CPT® 72197) OR
    - CT Pelvis with contrast (CPT® 72193)
  - Vaginal Fistula:
    - Enterovaginal, Colovaginal, Rectovaginal or Anovaginal:
      - Anoscopy and/or proctoscopy
      - Endoanal ultrasound (rarely used)
      - MRI Pelvis with and without contrast (CPT® 72197) is medically necessary as the initial modality for suspected enterovaginal fistula
      - CT Pelvis with contrast (CPT® 72193) is medically necessary if:
        - MRI contraindicated OR urgent evaluation of acute diverticulitis OR early postoperative period
    - Urinary Vaginal Fistula (Ureterovaginal, Vesicovaginal, or Urethrovaginal) - the following are medically necessary:
      - Cystoscopy
      - CT urography (CT Abdomen and Pelvis without and with contrast CPT® 74178) and/or CT cystography (CT Pelvis without contrast CPT® 72192) or
      - MRI Pelvis with and without contrast (CPT® 72197)

Background and Supporting Information

- A vaginal fistula is an abnormal communication between the vagina and either a portion of the digestive system or the urinary tract
  - Causes of vaginal fistula may include IBD, endometriosis, infection, tumor, radiation, obstetrical trauma and surgical injuries.
  - Symptoms of vaginal fistula-Persistent vaginitis, dyspareunia, perineal dermatitis, foul-smelling vaginal discharge, and/or urinary or fecal incontinence.
- A rectovesicular fistula is an abnormal communication between the rectum and the bladder.
  - Causes of rectovesicular fistula may include chronic infection, cancer, diverticulitis, IBD, radiation and surgical injuries.
  - Symptoms of rectovesicular fistula-Bubbles in the urine, brown or cloudy urine, blood in the urine, painful urination, recurrent urinary tract infection, and/or abdominal pain

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion (PV-21.3)

- MRI has been established as a method of delineating vaginal fistulas. This is secondary to its excellent soft tissue resolution, allowing identification of acute inflammatory changes, post-surgical fibrosis, neoplastic tissue and abscesses[3]. It also has the benefit of lacking ionizing radiation, but may have limited access as compared with CT. MRI is also contraindicated by the presence of metallic foreign body or MRI-incompatible devices, such as some pacemakers[3]. Studies have shown a positive predictive value of 92% for delineation of anorectal vaginal fistulas[4].
- CT can also be utilized in the visualization of fistulas[3,6]. It does have lower contrast resolution than MRI[3] and does carry the risk of ionizing radiation. It may be beneficial in emergent situations given the wide availability or in situations where an MRI is contraindicated. CT-urography/cystography is also a mainstay in evaluation of the urinary tract and can be utilized to evaluate urinary vaginal fistulas[3].

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Pilonidal Cyst (PV-21.4)

PV.PA.0021.4.A
v2.0.2026

- Advanced imaging is not medically necessary for pilonidal cyst disease[9].
  - History and physical exam are sufficient for diagnosis of pilonidal cyst.
- If other underlying etiologies are suspected, refer to appropriate guidelines:
  - For suspected osteomyelitis, see: **General Infection/Osteomyelitis (MS-9.1)** in the Musculoskeletal Imaging Guidelines
  - For abdominal fistulae, see: **Fistulae (AB-48)** in the Abdomen Imaging Guidelines
  - For suspected spinal dysraphism, see: **Cutaneous Indications to Suspect Occult Spinal Dysrpahism (PEDSP-4.2)** in the Pediatric Spine Imaging Guidelines

Evidence Discussion (PV-21.4)

- Pilonidal cysts most frequently arise in the natal cleft, the groove between the buttocks overlying the sacral area. Asymptomatic disease usually does not require any treatment. Acute and chronic infections can be evaluated sufficiently with history and physical alone[9]. Advanced imaging is limited to concern for complicated disease (See **General Infection/Osteomyelitis - MS-9.1**).

Urinary Incontinence – Initial Imaging (PV-22.1)

PV.IN.0022.1.A
v2.0.2026

- Initial Imaging, associated with other evaluations, are medically necessary as follows:
  - Non-Neurogenic Incontinence
    - Measurements of post void residual urine by Bladder ultrasound (CPT® 51798) OR Bladder catheterization
    - In addition to post void residual volume determination, screening for UTI should be considered
  - Neurogenic Incontinence
    - Ultrasound urinary tract (CPT® 76770 or CPT® 76775)

Background and Supporting Information

Urinary incontinence can be “stress,” “urgency,” or mixed; neurogenic or non-neurogenic; and complicated or uncomplicated. Neurogenic incontinence can occur from cerebral, spinal or peripheral neurological diseases.

Evidence Discussion (PV-22.1)

- The workup of urinary incontinence involves a thorough history and physical examination[2,6]. For incontinence due to non-neurogenic causes, advanced imaging is rarely necessary in the initial evaluation[2]. Assessment of the urine post void residual may be completed either with bladder ultrasound or urethral catheterization[6].
- Baseline imaging should be obtained in the evaluation of neurogenic urinary incontinence with renal bladder ultrasound[14].

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Urinary Incontinence – Further Imaging (PV-22.2)

PV.IN.0022.2.A
v2.0.2026

- CT Abdomen and Pelvis, contrast as requested, or CT Pelvis, contrast as requested, is medically necessary for any of the following:
  - Abnormality on ultrasound that requires further evaluation
  - Complicated incontinence
    - Failed conservative treatment
    - Pain or dysuria
    - Hematuria
    - Recurrent infection
    - Previous radical pelvic surgery
    - Suspected fistula
    - Suspected mass
    - Previous pelvic or prostate irradiation
  - Suspected fistulae
  - Detecting ectopic ureters if ultrasound is non-diagnostic
  - Pre-operative planning for complicated incontinence when ordered by or in consultation with the operating physician
- For neurogenic urinary incontinence See **Red Flag Indications (SP-1.2)** and **Myelopathy (SP-7.1)** in the Spine Imaging Guidelines and **Dementia (HD-8.1)** and **Normal Pressure Hydrocephalus (NPH) (HD-8.4)** in the Head Imaging Guidelines.

Evidence Discussion (PV-22.2)

- Urinary incontinence that has failed a trial of conservative treatment may require advanced imaging with CT of the abdomen and/or pelvis with or without contrast[2]. Advanced imaging may also be ordered for pre-operative planning if requested by the surgeon or to follow up on an abnormality noted on previous ultrasound[6].
- Other clinical scenarios where advanced imaging may be medically necessary are incontinence occurring concomitantly with abdominal or pelvic pain, dysuria or hematuria, or in the setting of recurrent urinary tract infections[2]. Incontinence in the setting of previous radical pelvic surgery or radiation may also require advanced imaging[14].
- If there is suspicion of a fistula, mass, or ectopic ureters (and ultrasound is non-diagnostic), advanced imaging with CT may be indicated[6].

Pelvic Prolapse (PV-22.3)

PV.IN.0022.3.U
v2.0.2026

- Transvaginal (TV) ultrasound (CPT® 76830) and/or Transperineal ultrasound (CPT® 76872) is medically necessary as the initial study of choice
  - Pelvic ultrasound (CPT® 76856 or CPT® 76857) is medically necessary if requested as a complimentary study.
- Urodynamic testing may be helpful if there is incontinence with a stage II or greater prolapse or voiding dysfunction
- MRI Pelvis (CPT® 72195 or CPT® 72197) is medically necessary for the following:
  - Pelvic floor anatomy and pelvic organ prolapse evaluations if exam and TV ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76856 or CPT® 76857) are equivocal; or
  - Pre-operative planning for complex organ prolapse when ordered by or in consultation with the operating physician; or
  - Persistent incontinence following surgery
- Mesh and Graft complications
  - Diagnostic evaluation for mesh and graft complications may include colonoscopy, cystoscopy, and/or urodynamics
  - Transvaginal (TV) ultrasound (CPT® 76830) and/or Pelvic ultrasound (CPT® 76856 or CPT® 76857), CT Abdomen and/or Pelvis, contrast as requested, MRI Pelvis without contrast or without and with contrast (CPT® 72195 or CPT® 72197) are medically necessary depending on the mesh and graft complication
- Sacral osteomyelitis may be a complication of sacrocolpopexy. MRI Pelvis with and without contrast (CPT® 72197) is medically necessary for lower back pain and/or suspected sacral osteomyelitis after this procedure.
- MRI (MRI Pelvis without contrast CPT® 72195) for Defecography is considered investigational/experimental by UHC.

Evidence Discussion (PV-22.3)

- The mainstay of evaluation of pelvic organ prolapse remains clinical pelvic examination. This allows for direct evaluation of prolapse and calculation prolapse quantification[3,15].
- Translabial, transperineal or transvaginal ultrasound have shown correlation with[3,15]. Ultrasound also allows for real-time evaluation, has wide availability, fast access, and lack of ionizing radiation exposure.
- MRI has been shown to have excellent soft tissue delineation. It circumstances were clinical exam and ultrasound are equivocal, MRI may provide additional information for conditions such as enterocele, sigmoidocele and intussusception[15].

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Complications related to mesh and graft placement in pelvic floor surgery are diverse in nature[4]. Work up for suspected complication is complex and may include a diverse range of diagnostic procedures such as radiologic imaging, cystoscopy, and colonoscopy. Surgical meshes have variable visibility[12]. Given the varied nature of this these complications modality of imaging should be tailored to suspected complication.
- A known rare complication of sacrocolpopexy is sacral osteomyelitis. In cases of suspected osteomyelitis, MRI is the preferred imaging as it has a very high sensitivity for detection infection, especially in early stages[12].

Fecal Incontinence (PV-22.4)

PV.IN.0022.4.U
v2.0.2026

The evaluation of fecal incontinence generally proceeds as follows:

- Determine the severity of the incontinence (Bristol Stool Scale, Fecal Incontinence Severity Index, etc.)
- History and Physical to include digital rectal examination and perianal pinprick (to assess for neurogenic causes)
- Trial of conservative management
- Diagnostic Testing if symptoms persist to include:
  - Ano-rectal Manometry
  - Balloon Expulsion Test
  - Endoanal ultrasound (CPT® 76872) to confirm sphincter defects in individuals with suspected sphincter injury (e.g. history of vaginal delivery or anorectal surgery)
  - MRI Pelvis (CPT® 72197) is medically necessary if:
    - Ano-rectal manometry suggests weak sphincter pressures AND/OR there is an abnormal balloon expulsion test AND
    - There has been a failure of a trial of conservative management since the onset of or change in symptoms AND
    - Surgery is being considered
- MRI (MRI Pelvis without contrast (CPT® 72195) for Defecography is considered investigational/experimental by UHC.

Background and Supporting Information

With regards to fecal incontinence ACG Guidelines stated that “the internal sphincter is visualized more clearly by endoanal ultrasound, whereas MRI is superior for discriminating between an external anal sphincter tear and a scar and for identifying external sphincter atrophy.

However, guidelines adopted by the American Society of Colon and Rectal Surgeons stated that “Endoanal ultrasound is a useful and sensitive tool in the evaluation of patients with FI (fecal incontinence), especially when there is a history of vaginal delivery or anorectal surgery. Ultrasound can reliably identify internal and external sphincter defects that may be associated with sphincter dysfunction.” In addition, the guidelines note “Other modalities (eg, MRI) have shown substantial interobserver variability and, at this point, are likely inferior to ultrasound imaging, but they may provide additional information where endoanal ultrasound is unavailable.”

Click Here to Return to the Main TOC

Evidence Discussion (PV-22.4)

- According to the American College of Gastroenterology, the American Society of Colon and Rectal Surgeons and the American College of Obstetrics and Gynecology, complete history and physical exam is essential for the evaluation of patient with fecal incontinence[1,5,10].
- For individuals that fail conservative measures, ano-rectal manometry and rectal balloon expulsion testing should be performed. This may help to guide additional treatment and diagnostic testing[1].
- Endoanal ultrasound (EAUS) can be considered in individuals with suspected sphincter injury[1,5]. Ultrasound is widely available and well tolerated, however it is operator-dependent[16]. EAUS shows very good interobserver agreement in the diagnosis of sphincter defects and the measurement of the internal anal sphincter[16].
- MRI has also emerged as an imaging modality for evaluation of fecal incontinence. While EAUS is superior for the evaluation of the internal anal sphincter, MRI shows better distinction between fat and muscle in the evaluation of the external anal sphincter[16]. MRI is limited by the fact that it is not as readily available and is unsuitable for patients with limiting conditions such as metal implants and claustrophobia[16]. MRI defecography also may play a role in the evaluation of fecal incontinence as it allows for insight into important functional disorders related to defecation[16].

Patent Urachus (PV-23.1)

PV.UR.0023.1.A
v2.0.2026

- Drainage from the umbilicus, redness around umbilicus, abdominal pain, or urinary tract infection from persistent fetal connection between the bladder and the umbilicus:
  - Ultrasound (CPT® 76856 or CPT® 76857 and/or CPT® 76700 or CPT® 76705) or voiding cystourethrography (VCUG) (CPT® 74455) is medically necessary for suspected patent urachus
  - CT Pelvis with contrast (CPT® 72193) or MRI Pelvis without contrast (CPT® 72195) or with and without contrast (CPT® 72197) is medically necessary if the ultrasound is equivocal or if additional imaging is needed for surgical planning if there is a suspected urachal carcinoma or other urachal abnormality.

Evidence Discussion (PV-23)

- A patent urachus (connecting bladder to umbilicus) can manifest as redness around or drainage from the umbilicus, abdominal pain, or urinary tract infections[1].
- If suspected, ultrasound is indicated as the initial evaluation as it can be diagnostic without exposing the patient to radiation[2,3].
- Advanced imaging of the pelvis is indicated for inconclusive ultrasound or for surgical planning[1,3].

Bladder Mass (PV-24.1)

PV.BL.0024.1.A
v2.0.2026

- Bladder masses incidentally found on other imaging (ultrasound, cystoscopy or KUB):
  - CT Pelvis without contrast (CPT® 72192) for suspected bladder stone is medically necessary if initial imaging is equivocal or if surgery is planned
  - CT Pelvis without (CPT® 72192) is medically necessary for suspected bladder diverticuli
- See **Oncology Imaging Guidelines** for biopsy confirmed or suspected malignancy

Background and Supporting Information

Symptoms of bladder mass may include hematuria, urgency, frequency, chronic urinary infection, obstruction or urinary retention.

Evidence Discussion (PV-24.1)

- Symptoms of bladder mass may include hematuria, urgency or frequency of urination, urinary infection or urinary retention[1,4,5].
- Bladder masses may be found incidentally on initial imaging such as ultrasound, cystoscopy or KUB (Kidney, Ureter and Bladder X-ray).
- Suspected bladder stone may be further evaluated with CT pelvis if initial imaging is inconclusive or for surgical planning[5]. CT has a higher sensitivity than ultrasound for bladder stones[5].
- Suspected bladder diverticuli can be further evaluated with CT pelvis[1,4].

Ureteral and/or Bladder Trauma or Injury (PV-25.1)

PV.BT.0025.1.A
v2.0.2026

- Abdominal and/or Pelvic ultrasound (CPT® 76700 and/or CPT® 76856) is medically necessary if requested
- CT cystography (CT Pelvis without contrast CPT® 72192) is medically necessary for suspected bladder injury
- CT Abdomen and Pelvis with OR with and without contrast (CPT® 74177 or CPT® 74178) is medically necessary if:
  - Suspected iatrogenic/operative injury OR
  - Blunt trauma and suspected bladder or ureteral injury with one or more of the following (See **Blunt Abdominal Trauma (AB-10.1)** in the Abdomen Imaging Guidelines):
    - Abdominal pain or tenderness
    - Pelvic or femur fracture
    - Hematocrit <30%
    - Hematuria
    - Non-examinable individual (intoxicated, less than fully conscious, Glasgow Coma Scale Score >13, etc.)
    - Evidence of abdominal wall trauma or seat-belt sign
    - Rapid deceleration injury

Background and Supporting Information

Bladder trauma: CT cystography- CT Pelvis without contrast allowing the radiologist or Urologist to instill contrast to r/o bladder injury and/or perforation.

Ureteral injury: "*Iatrogenic ureteral injuries can occur during gynecologic, obstetric, urologic, colorectal, general, or vascular surgery; gynecologic surgery accounts for more than half of all iatrogenic injuries.*"[2]

Evidence Discussion (PV-25)

- Ultrasound can performed for suspected ureteral and/or bladder trauma. It may aid in triage of injuries and may lead to immediate surgical intervention rather than additional imaging. However it has lower sensitivity compared to CT, particularly in genitourinary injury[4].
- For individuals with suspected bladder injury retrograde cystography is appropriate[2]. CT cystography has a reported 95-100% sensitivity and specificity for the diagnosis of

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

bladder rupture[3,4]. It has the benefits of being widely available and accurate, but does have exposure to ionizing radiation.

- Those presenting with suspected ureteral injury CT of the abdomen and pelvis is appropriate for evaluation of the complete urinary tract. Imaging with contrast is preferred for evaluation of as it has higher sensitivity for detecting concurrent visceral organ and vascular injuries[3]. Urogram is helpful in further evaluation of the ureters [2] as it may show contrast extravasation from the ureter or partial or complete ureteral obstruction[1].

Gender Affirmation Surgery; Pelvic (PV-26.1)

PV.GA.0026.1A
v2.0.2026

- Preoperative imaging is medically necessary as outlined below if the individual has a health plan benefit covering pelvic gender affirmation surgery. Preoperative imaging is not medically necessary if pelvic gender affirmation surgery is not a health plan covered benefit.
- Preoperative imaging:
  - Metoidioplasty
    - Preoperative imaging is not medically necessary
  - Phalloplasty
    - Muscular flaps used for neophallus creation are generally obtained from anterior lateral thigh (pedicled flap) or forearm (radial free flap)
      - For planned radial free flap, upper extremity CT angiography (CPT® 73206) of anticipated donor site (unilateral) for evaluation of perforator anatomy.
      - For planned anterior lateral thigh flap, bilateral lower extremity CT angiogram (CPT® 73706)
      - If iodinazed contrast allergy, MRA (contrast as requested)
  - Vaginoplasty
    - Preoperative imaging is not supported
- Postoperative complications:
  - Doppler ultrasound is medically necessary when:
    - Monitoring of flap perfusion after phalloplasty for suspected vascular insufficiency
  - CT Abdomen and Pelvis OR CT Pelvis (contrast as requested - CPT® 74176, CPT® 74177, CPT® 74178, CPT® 72192, CPT® 72193, or CPT® 72194) is medically necessary for suspected postoperative complications
    - Complications after surgery may include hematoma, seroma, abscesses, fistula, urinary tract injury, etc. (See **Ureteral and/or Bladder Trauma or Injury (PV-25.1)** for ureteral and/or bladder injury)
  - MRI Pelvis with and without contrast (CPT® 72197) is medically necessary for:
    - Suspected fistula
    - Non diagnostic CT scan AND further imaging is needed for treatment planning

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Background and Supporting Information

- Metoidioplasty-Metoidioplasty is a procedure using clitoral hypertrophy and clitoral release to form masculine-appearing external genitalia
- Phalloplasty-Phalloplasty includes the creation of a neophallus using muscular flaps
- Vaginoplasty-Vaginoplasty refers to the surgical creation of a vulva and vaginal canal

Evidence Discussion (PV-26)

- Routine preoperative imaging is not supported for metoidioplasty or Vaginoplasty[2,4,5].
- CT angiography is indicated for preoperative evaluation for phalloplasty in order to map size, location and course of the vasculature[4,7]. CTA has been found to have high accuracy in perforator detection (sensitivity of 96-100% and specificity of 95-100% in studies investigating abdominal perforators), short time for image acquisition and high reproducibility. It however does carry the risk of ionizing radiation and exposure to iodinated contrast[8].
- Doppler ultrasound allows for monitoring of vascular perfusion of the neophallus after phalloplasty[4,5]. Ultrasound is readily available and does not carry risk of ionizing radiation.
- Expert opinion has stated that CT would be indicated for postoperative complications of gender affirmation surgery[2,4,5,7]. CT allows for fast and accurate identification of common postoperative complications such as abscess, hematoma and seroma. CT angiography aids in the diagnosis of arterial or venous thrombosis as well as identification of arterial bleeding in the setting of hemorrhage. CT does carry the risk of ionizing radiation and iodinated contrast allergy.
- MRI is the preferred modality for suspected fistula given its superior soft tissue delineation in these cases[2].

General Guidelines (PN-1.0)

PN.GG.0001.0.A
v1.0.2026

- A pertinent clinical evaluation is required before advanced imaging can be considered. The clinical evaluation should include a pertinent history and physical examination, including a neurological examination (since the onset or change in symptoms), appropriate laboratory studies, non-advanced imaging modalities, and electromyography/nerve conduction (EMG/NCV) studies. Other meaningful technological contact (telehealth visit, telephone call or video call, electronic mail or messaging) since the onset or change in symptoms, by an established individual can serve as a pertinent clinical evaluation.
- Nerve conduction studies are often normal early in the disease course with changes occurring from 1 to 4 weeks after symptom onset in the majority of individuals. This will be taken into consideration on a case-by-case basis in regards to the EMG/NCV requirement in each section requirement of the Peripheral Nerve and Neuromuscular Disorders (PNND) Imaging Guidelines.
- Due to the termination of the federal public health emergency declaration, the COVID-19 pandemic is no longer considered an indication to waive electrodiagnostic (EMG/NCV) study requirements within the Peripheral Nerve and Neuromuscular Disorders Imaging Guidelines.
- If imaging of peripheral nerves is medically necessary, ultrasound is the preferred modality for superficial peripheral nerves. MRI may be used for imaging deep nerves such as the lumbosacral plexus or nerves obscured by overlying bone such as the brachial plexus or for surgical planning. CT is limited to cases in which MRI is contraindicated.

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

Evidence Discussion (PN-1.0)

- Electromyography (EMG) and nerve conduction velocity (NCV) studies are useful in establishing the origin of peripheral nerve pathology and in guiding further

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

diagnostic evaluation. Needle EMG following traumatic nerve injury may detect denervation of muscles that do not seem clinically affected. The optimal time to search for denervation changes is 10 to 14 days after the injury. Needle EMG may show residual innervation to paralyzed muscles. Follow-up EMG and NCV studies may demonstrate early evidence of re-innervation or evolving abnormalities that objectively demonstrate the temporal course of peripheral nerve pathology.

- Deferring EMG due to COVID-19 is less relevant at this time.
- For superficial peripheral nerves, ultrasound has significantly higher resolution than MRI. In terms of expense, safety, and noninvasiveness, ultrasound has clear advantages over MRI and the few comparative reports available confirm the value of ultrasound as an initial imaging choice.
- Advantages of ultrasound over MRI for detecting peripheral nerve pathology include lower cost, rapidity of examination, higher spatial resolution, imaging of the nerve in continuity, and ease of side-to-side comparisons. Ultrasound may better detect subtle changes in nerve caliber. This is important because peripheral nerve pathology is often fusiform in shape and can extend along the length of the nerve without greatly altering its cross-section area. MRI frequently misses multifocal (71%) and occasionally single pathologies.
- Advantages of MRI over ultrasound include superior contrast between tissues, imaging of structures that are deep or surrounded by bone, and tissue characterization using multi-sequence analysis and IV contrast.
- There is greater accuracy (96%) of diagnoses in cases of peripheral nerve sheath tumor, traumatic neuroma or neuropathy, idiopathic mono-neuropathy or plexopathy, fibrosis of nerves, nerve compression caused by ganglion or synovial cysts or any other soft tissue structures, non-neural soft tissue tumors, intra-neural granulomas, and vasculitis with ultrasound than MRI.

Focal Neuropathy (PN-2.1)

PN.FN.0002.1.A
v1.0.2026

Focal Disorder	EMG/NCV Initially?	Advanced Imaging
Carpal Tunnel Syndrome	YES	• When EMG/NCV and clinical findings are equivocal **AND** only when requested for pre-operative planning, MRI Upper Extremity Joint (Wrist) without contrast (CPT® 73221) is medically necessary. • For radiculopathy, see **Neck (Cervical Spine) Pain Without/With Neurological Features (Including Stenosis) and Trauma (SP-3)** in the Spine Imaging Guidelines.
Ulnar Neuropathy	YES	After EMG/NCV, only **ONE** of the following is medically necessary if requested for surgical consideration: • MRI Upper Extremity Joint (Elbow or Wrist) without contrast (CPT® 73221) **OR** • MRI Upper Extremity Other Than Joint (Forearm or Hand) without contrast (CPT® 73218)
Radial Neuropathy	YES	• MRI Upper Extremity Other Than Joint (Arm or Forearm) without contrast (CPT® 73218) when surgery is being considered. • MRI Upper Extremity Other Than Joint (Arm or Forearm) without and with contrast (CPT® 73220) if there is a suspicion of a nerve tumor such as a neuroma.
Radial Neuropathy Notes: Leads to wrist drop with common sites of entrapment at the inferior aspect of the humerus (Saturday night palsy) or the forearm (posterior interosseous syndrome). Entrapment of the nerve at the wrist (Wartenberg syndrome or handcuff palsy) typically spares motor involvement and results only in sensory changes. Trauma or fractures of the humerus, radius, or ulna can damage the radial nerve.		

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Focal Disorder	EMG/NCV Initially?	Advanced Imaging
Pudendal Neuropathy	NO	• **Documented concern specifically for pudendal neuropathy, pudendal neuralgia, or pudendal entrapment**: MRI Pelvis without contrast (CPT® 72195) **OR** MRI Pelvis without and with contrast (CPT® 72197) ◦ If there is a contraindication to MRI **and** the above documented concern is present, then **ONE** of the following is medically necessary: ▪ CT Pelvis without contrast (CPT® 72192) ▪ CT Pelvis with contrast (CPT® 72193) ▪ CT Pelvis without and with contrast (CPT® 72194) • For all other pelvic concerns, see the following Pelvic Imaging Guidelines (as indicated): ◦ **Pelvic Pain/Dyspareunia Female (PV-11.1)** ◦ **Impotence/Erectile Dysfunction (PV-17.1)** ◦ **Male Pelvic Disorders (PV-19.1)** ◦ **Scrotal Pathology (PV-20.1)**
Pudendal Neuropathy Notes: Causes pain, sexual dysfunction, or sensory change in the genitals, perineum, and perianal region. May be caused by trauma, recurrent injury from exercise such as cycling, pelvic mass, or after viral infection (e.g., post-herpetic neuralgia).		
Sciatic Neuropathy	YES	• MRI Pelvis without contrast (CPT® 72195) • CT Pelvis without contrast (CPT® 72192) is **NOT** routinely medically necessary due to lack of soft tissue contrast. ◦ It should only be performed in the rare circumstance of contrast allergy and/or contraindication to MRI such as pacemaking device.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Focal Disorder	EMG/NCV Initially?	Advanced Imaging
Sciatic Neuropathy Notes: May be caused by trauma to the gluteal area with hematoma, injection palsy, hip or pelvic fractures, or hip replacement (arthroplasty). **Piriformis Syndrome** involves entrapment of the sciatic nerve at the sciatic notch in the pelvis by a tight piriformis muscle band. Concerns for piriformis syndrome should be imaged according to the sciatic neuropathy criteria.		
Femoral Neuropathy	NO	• MRI Pelvis without contrast (CPT® 72195)
Femoral Neuropathy Notes: May occur as a complication of pelvic surgery in females or those on anticoagulants with retroperitoneal bleeding, or as a mononeuropathy in diabetics		
Meralgia Paresthetica	NO	• MRI Pelvis without contrast (CPT® 72195) is medically necessary for **ANY** of the following scenarios: ◦ Cases of diagnostic uncertainty ◦ Pre-operative planning • CT Pelvis without contrast (CPT® 72192) is **NOT** routinely medically necessary due to lack of soft tissue contrast. ◦ It should only be performed in the rare circumstance of contrast allergy and/ or contraindication to MRI such as pacemaking device.
Meralgia Paresthetica Notes: Sensory loss in the lateral femoral cutaneous nerve as it exits the pelvis under the inguinal ligament (lateral thigh without extension into lower leg), and is usually diagnosed based on a careful history and physical exam. EMG/NCV testing is often technically difficult and not required.		
Peroneal Neuropathy	YES	• MRI Lower Extremity Joint (Knee) without contrast (CPT® 73721) **OR** MRI Lower Extremity Other Than Joint without contrast (CPT® 73718) when surgery is considered or when ordered by or in consultation with a surgeon.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Focal Disorder	EMG/NCV Initially?	Advanced Imaging
Tarsal Tunnel Syndrome	N/A	• See **Soft Tissue Mass and Morton's Neuroma (MS-10.3)** in the Musculoskeletal Imaging Guidelines.

- For phrenic nerve concerns and evaluation of diaphragmatic weakness, refer to **Elevated Hemidiaphragm (CH-30)**.

Evidence Discussion (PN-2.1)

- Focal neuropathies are typically diagnosed by a combination of clinical history, thorough neurological examination, and electrodiagnostic testing with electromyography (EMG) and nerve conduction studies (NCS).
- When clinical evaluation and electrodiagnostic testing are inconclusive, MRI may allow for better identification and anatomic localization of lesions and is considered the gold standard for imaging of the peripheral nerve.
- The sensitivity and specificity of MRI findings for carpal tunnel syndrome are low (sensitivity, 23%–96%; specificity, 39%–87%), and for this reason MRI imaging does not play a role in the routine clinical assessment of carpal tunnel syndrome. However, MRI of the wrist can help identify surgical candidates when clinical and electrodiagnostic findings are inconclusive.
- When caused by nerve entrapment or compression, focal neuropathies may benefit from surgical release or decompression. MRI can provide visualization of the cause of compression, rule out other causes of nerve injury, and allow for a more focused operative approach, particularly when surgery is considered to decompress common entrapment neuropathies of the ulnar, radial, and peroneal nerves.
- Sciatic, femoral, and pudendal neuropathies often occur secondary to trauma, compression, or entrapment of the affected nerve. These are often diagnosed clinically or localized with electrodiagnostic testing. MRI imaging of the pelvis may be medically necessary to assess for sources of compression, including occult malignancy.
- Meralgia paresthetica is the common term describing pathology of the lateral femoral cutaneous nerve of the thigh. The nerve is prone to injury and compression but may have a variable anatomic course. Meralgia paresthetica is primarily diagnosed by clinical history and exam, as neuroimaging and electrodiagnostic testing results may be difficult to interpret. Neuroimaging is most useful in cases of diagnostic uncertainty, particularly when surgical exploration and treatment are considered.

Polyneuropathy (PN-3.1)

PN.PN.0003.1.A
v1.0.2026

Poly-Disorder	EMG/NCV Initially?	Advanced Imaging	Comments
Polyneuropathies with Central Nervous System (CNS) Involvement	YES	If clinical findings point to abnormalities in those areas, then **ANY** of the following are medically necessary: • MRI Brain without and with contrast (CPT® 70553), **AND/OR** • MRI Cervical Spine without and with contrast (CPT® 72156), **AND/OR** • MRI Thoracic Spine without and with contrast (CPT® 72157), **AND/OR** • MRI Lumbar Spine without and with contrast (CPT® 72158)	Examples: Guillain-Barré syndrome, inflammatory polyneuropathies unspecified, and Lyme disease
AIDS-Related Cytomegaloviral Neuropathy/ Radiculopathy	YES	• MRI Lumbar Spine without and with contrast (CPT® 72158) • If concern for myelopathy, **ANY** of the following imaging are **ALSO** medically necessary: ◦ MRI Cervical Spine without and with contrast (CPT® 72156) **AND/OR** ◦ MRI Thoracic Spine without and with contrast (CPT® 72157)	• Often presents with urinary retention and a clinically confusing picture in the legs. • For myelopathic signs and symptoms, see **Myelopathy (SP-7.1)** .

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Poly-Disorder	EMG/NCV Initially?	Advanced Imaging	Comments
Chronic Inflammatory Demyelinating Polyneuropathy (CIDP)	YES	MRI Lumbar Spine without and with contrast (CPT® 72158) **AND/OR** MRI Cervical Spine without and with contrast (CPT® 72156) if diagnosis uncertain following EMG/NCV. • For imaging requests of the brachial or lumbosacral plexus or muscle: See **Brachial Plexus (PN-4.1)**, **Lumbar and Lumbosacral Plexus (PN-5.1)**, and **Muscle Diseases (PN-8.5)**	
Multifocal Motor Neuropathy	YES	If diagnosis is uncertain following EMG/NCV, MRI of the Brachial Plexus is medically necessary with **ONE** of the following: • MRI Upper Extremity Other Than Joint without and with contrast (CPT® 73220) • MRI Chest without and with contrast (CPT® 71552) • MRI Neck without and with contrast (CPT® 70543)	
POEMS (Polyneuropathy, Organomegaly, Endocrinopathy, M-protein, Skin changes)	YES	Advanced imaging is for the non-neurological etiologies of this rare osteosclerotic plasmacytoma syndrome.	See **Multiple Myeloma and Plasmacytomas (ONC-25)** in the Oncology Imaging Guidelines.
Subacute Sensory Neuronopathy & Other Paraneoplastic Demyelinating Neuropathies	YES	• Advanced imaging should be guided by specific clinical concern (see relevant guideline). • For evaluation of suspected paraneoplastic syndromes, see **Paraneoplastic Syndromes (ONC-30.3)** in the Oncology Imaging Guidelines.	

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Background and Supporting Information

- Central nervous system (CNS) imaging (brain and spinal cord) is not required for polyneuropathy without CNS signs/symptoms.
- Distal symmetric polyneuropathy is the most common pattern of generalized peripheral neuropathy. It is typically sensory predominant and may demonstrate neurological abnormalities including reduced or absent deep tendon reflexes (DTRs), reduced sensation to multiple testing modalities (vibration, proprioception, etc). In more advanced staging, mild motor weakness may be present. It is most often associated with diabetes and metabolic abnormalities. In the absence of atypical findings (such as asymmetrical presentation, significant weakness, or upper motor neuron exam findings such as hyperreflexia or spasticity), distal symmetric polyneuropathy does not require CNS imaging.

Evidence Discussion (PN-3.1)

- Polyneuropathies are typically diagnosed by a combination of clinical history, thorough neurological examination, lab work-up, and electrodiagnostic testing with electromyography (EMG) and nerve conduction studies (NCS).
- For systemic polyneuropathies with potential for CNS involvement, such as Lyme disease-related polyneuropathy and some inflammatory polyneuropathies, MRI imaging of the brain and/or spinal cord may be helpful to identify typical patterns of involvement or to rule out other pathologies when clinical findings suggest CNS involvement.
- Neuropathy is the most common neurological complication of human immunodeficiency virus (HIV) infection and, in its most common form, is treated with symptom management and anti-viral therapy. However, other acquired immunodeficiency syndrome (AIDS)-related neurological disorders may be difficult to clinically differentiate from common HIV polyneuropathy and may require more aggressive treatment. Accurate diagnosis of AIDS-related cytomegalovirus (CMV) polyradiculopathy, HIV vasculitis, or AIDS-related motor neuron disease is required for appropriate treatment. MRI imaging of the spinal cord or nerve roots may assist with diagnosis when medically necessary.
- Chronic acquired demyelinating polyneuropathies, including chronic inflammatory demyelinating polyneuropathy (CIDP) and multifocal motor neuropathy (MMN), are diagnosed by clinical history and results of electromyography and nerve conduction studies. If the diagnosis remains uncertain after these studies, neuroimaging may help establish the diagnosis. Evidence of lumbar nerve root involvement on MRI Lumbar Spine is supportive of a CIDP diagnosis. T2-weighted signal change on MRI of the brachial plexus is often present in MMN individuals.
- Polyneuropathy, organomegaly, endocrinopathy, M-protein, skin changes (POEMS) syndrome is a disorder affecting multiple organ systems which occurs in the setting of a plasma cell disorder. Diagnosis is based on electrodiagnostic confirmation of polyneuropathy and work-up of the underlying oncologic condition.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Electrodiagnostic testing can provide valuable findings in the investigation of some paraneoplastic polyneuropathies; however, identification of the underlying malignancy and appropriate oncological management are key to management.

Brachial Plexus (PN-4.1)

PN.BP.0004.1.A
v1.0.2026

- EMG/NCV examination is required prior to advanced imaging except in cases of malignant infiltration or radiation plexitis as detailed below.

Brachial Plexus Imaging		
Indication	**Imaging**	**Notes**
Malignant infiltration (EMG not required)	Any **ONE** of the following: • MRI Upper Extremity Other Than Joint without contrast (CPT® 73218) • MRI Upper Extremity Other Than Joint without and with contrast (CPT® 73220) • MRI Chest without contrast (CPT® 71550) • MRI Chest without and with contrast (CPT® 71552) • MRI Neck without contrast (CPT® 70540) • MRI Neck without and with contrast (CPT® 70543)	
Radiation plexitis to rule out malignant infiltration (EMG not required)		
Neurogenic thoracic outlet Syndrome (TOS)		
Preoperative work-up requiring evaluation of the brachial plexus		
Brachial plexitis (Parsonage-Turner syndrome or painful brachial amyotrophy)	• Any **ONE** of the above studies **AND** • If there is concern for radiculopathy in addition to plexopathy, MRI Cervical Spine without contrast (CPT® 72141)	• For concern for cervical radiculopathy, see **Neck (Cervical Spine) Pain Without/With Neurological Features (Including Stenosis) and Trauma (SP-3)** • For details of brachial plexitis (Parsonage-Turner syndrome), see **Background and Supporting Information**.
Traumatic injury		

- MRI Chest and Neck are inherently bilateral, whereas MRI Upper Extremity is unilateral.
- If MRI is not available or is contraindicated, CT offers the next highest level of anatomic visualization and can characterize local osseous or vascular anatomy

Proprietary Information of UnitedHealthcare.

and injury. In this circumstance, when the above criteria are met, only **ONE** of the following studies is medically necessary:
  - **CT Neck Soft Tissue**: CT Neck without contrast (CPT® 70490), **or** CT Neck with contrast (CPT® 70491), **or** CT Neck without and with contrast (CPT® 70492)
  - **CT Upper Extremity**: CT Upper Extremity without contrast (CPT® 73200), **or** CT Upper Extremity with contrast (CPT® 73201), **or** CT Upper Extremity without and with contrast (CPT® 73202)
  - **CT Chest**: CT Chest without contrast (CPT® 71250), **or** CT Chest with contrast (CPT® 71260), **or** CT Chest without and with contrast (CPT® 71270)
- MRI should be performed prior to consideration of PET imaging.
  - For PET imaging, see **PET Imaging in Oncology (ONC-1.4)** in the Oncology Imaging Guidelines.

Background and Supporting Information

- Brachial plexitis (Parsonage-Turner syndrome or painful brachial amyotrophy) is a self-limited syndrome characterized by initial shoulder region pain followed by weakness of specific muscles in a pattern which does not conform to involvement of a single root or distal peripheral nerve.

Evidence Discussion (PN-4.1)

- MRI is the imaging study of choice to evaluate the brachial plexus due to superior soft-tissue contrast and good spatial resolution, providing detailed definition of intraneural anatomy as well as localizing pathologic lesions in conditions in which electrodiagnostic and physical findings are nonspecific. A variety of findings may be seen within the brachial plexus on MRI, including increased T2 signal intensity, focal or diffuse enhancement, or enlargement or edema of nerve segments. Furthermore, signal abnormalities or atrophy in muscles supplied by the brachial plexus can help support a plexopathy. MRI is more sensitive than CT at identifying subtle infiltrative lesions regions or areas of enhancement.
- Regarding fluorine-18-2-fluoro-2-deoxy-D-glucose (FDG)-PET/CT, there is no relevant literature to support the use of FDG-PET/CT in the evaluation of traumatic or nontraumatic brachial plexopathy in the absence of a known malignancy.

Lumbar and Lumbosacral Plexus (PN-5.1)

PN.LP.0005.1.A
v1.0.2026

- EMG/NCV examination is required prior to advanced imaging.
  - EMG/NCV is **NOT** required if there is concern for malignant infiltration.
- For suspected lumbar and/or lumbosacral plexopathy, **ONE** of the following is medically necessary:
  - MRI Pelvis without contrast (CPT® 72195) with fat suppression imaging, **OR**
  - MRI Pelvis without and with contrast (CPT® 72197) with fat suppression imaging, **OR**
  - MRI Abdomen without contrast (CPT® 74181) and MRI Pelvis without contrast (CPT® 72195) with fat suppression imaging, **OR**
  - MRI Abdomen without and with contrast (CPT® 74183) and MRI Pelvis without and with contrast (CPT® 72197) with fat suppression imaging
- If suspected lumbar and/or lumbosacral plexopathy is due to a traumatic injury, then MRI Lumbar Spine without contrast (CPT® 72148) is **ALSO** medically necessary.
  - See **Low Back (Lumbar Spine) Trauma (SP-6.2)**
- If MRI is not available or is contraindicated, CT offers the next highest level of anatomic visualization and can characterize local osseous or vascular anatomy and injury. In this circumstance, when requested for suspected lumbar and/or lumbosacral plexopathy, **EITHER** of the following is medically necessary:
  - CT Pelvis with contrast (CPT® 72193) **OR**
  - CT Abdomen and Pelvis with contrast (CPT® 74177)
- For PET imaging, see **PET Imaging in Oncology (ONC-1.4)** in the Oncology Imaging Guidelines.

Background and Supporting Information

- Lumbar and lumbosacral plexopathy may be caused by any of the following:
  - Malignant infiltration
  - Radiation
  - Traumatic injury
  - Inflammation including sarcoidosis and infection
  - Toxicity, including iatrogenic during delivery (obstetric) or related to nerve blocks (e.g., Botox®)
  - Metabolic, including etiologies such as diabetes

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion (PN-5.1)

- MRI is the imaging study of choice to evaluate the lumbosacral plexus due to superior soft-tissue contrast and good spatial resolution, providing detailed definition of intraneural anatomy as well as localizing pathologic lesions in conditions in which electrodiagnostic and physical findings are nonspecific. Abnormal MRI findings in lumbosacral plexopathies include increased T2 signal intensity, focal or diffuse enhancement, or enlargement or edema of nerve segments. MRI is more sensitive than CT at identifying subtle infiltrative lesions, although CT may be useful to assess for psoas hematoma.
- Regarding fluorine-18-2-fluoro-2-deoxy-D-glucose (FDG)-PET/CT, there is no relevant literature to support the use of FDG-PET/CT in the evaluation of traumatic or nontraumatic lumbosacral plexopathy in the absence of a known malignancy.

Magnetic Resonance Neurography (MRN) (PN-7.1)

PN.MR.0007.1.A
v1.0.2026

- MRN is supported when **ALL** of the following criteria are met:
  - The study is to evaluate a traumatic or compressive focal neuropathy **or** a brachial plexus injury.
  - The study is requested by a neurosurgeon, orthopedic surgeon, neurologist, or podiatrist after an in-person clinical evaluation **AND** when surgery is being considered.
  - EMG/NCV has been performed and results provided.
  - The diagnosis remains unclear following prior imaging of the region with x-ray, ultrasound, or conventional imaging (CT or MRI).
    - For conventional imaging criteria, see **Focal Neuropathy (PN-2.1)** and **Brachial Plexus (PN-4.1)**.
- MRN is reported as **ONE** of the following:
  - Unlisted MRI procedure code (CPT® 76498) **OR**
  - MRI extremity with **ONE** of the following codes:
    - MRI Upper Extremity, Other Than Joint, without contrast (CPT® 73218)
    - MRI Upper Extremity, Other Than Joint, without and with contrast (CPT® 73220)
    - MRI Lower Extremity, Other Than Joint, without contrast (CPT® 73718)
    - MRI Lower Extremity, Other Than Joint, without and with contrast (CPT® 73720)
- MRN for **ANY** other indication is considered **NOT medically necessary** at this time, including for assessment of lumbosacral plexopathy, neuromuscular disease, and polyneuropathy.

Background and Supporting Information

Magnetic resonance neurography utilizes standard MRI equipment with sequences and technology that allow for optimized viewing of the peripheral nerve. MRN creates greater contrast between the nerve and other surrounding soft tissue to allow a detailed view of the nerve tissue and layers. This allows for more accurate diagnosis of the location and degree of nerve injury.

Evidence Discussion (PN-7.1)

- Magnetic resonance neurography (MRN) offers advantages over standard MRI imaging by utilizing sequences and technology that optimize viewing of the peripheral nerve. MRN presents no increased risk to safety over standard MRI.[1] MRN is a non-

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

invasive, accurate, reliable method of demonstrating normal and abnormal nerve and assessing regional muscle denervation with good surgical correlation to findings.

- Efficacy and reliability of MRN have been clinically validated in the diagnosis and localization of traumatic and compressive focal neuropathies and brachial plexus injuries for the purpose of surgical consideration. A clinical study assessing the impact of MRN data on surgical planning noted that review of MRN altered the suspected nerve involvement in 23% and changed the nerve injury grade in 27% of individuals studied. Surgeons reported MRN altered their determination of the need for surgery in 63%, timing of surgery in 41%, length of skin incision in 27%, and time in the operating room in 30% of cases reviewed. This data suggests that MRN may improve the selection of candidates for surgical repair of these lesions and may narrow the focus of surgery.
- There is insufficient literature to support the role of MRN for evaluation of other pathologies, including, but not limited to, lumbosacral plexopathy, neuromuscular disease, and polyneuropathy. Thus, MRN is considered not medically necessary at this time for indications other than traumatic and compressive focal neuropathies and brachial plexus injuries.

Motor Neuron Disease/Amyotrophic Lateral Sclerosis (ALS) (PN-8.1)

PN.ND.0008.1.A
v1.0.2026

- A neurological examination is **NOT** required for an individual with established diagnosis of motor neuron disease/ALS **or** when diagnosis is suspected by a neurologist, geneticist, or a physical medicine and rehabilitation (PM&R) specialist.
- For initial evaluation of suspected motor neuron disease/ALS, **ANY** of the following are medically necessary:
  - **Brain**: MRI Brain without contrast (CPT® 70551) **or** MRI Brain without and with contrast (CPT® 70553), **AND/OR**
  - **Cervical Spine**: MRI Cervical Spine without contrast (CPT® 72141) **or** MRI Cervical Spine without and with contrast (CPT® 72156), **AND/OR**
  - **Thoracic Spine**: MRI Thoracic Spine without contrast (CPT® 72146) **or** MRI Thoracic Spine without and with contrast (CPT® 72157), **AND/OR**
  - **Lumbar Spine**: MRI Lumbar Spine without contrast (CPT® 72148) **or** MRI Lumbar Spine without and with contrast (CPT® 72158)
- Repeat imaging can be evaluated based on the appropriate **Spine Imaging Guidelines.**

Background and Supporting Information

- Evidence of lower motor neuron dysfunction in a muscle may include clinical examination of muscle weakness/wasting or EMG abnormalities to meet the criteria for the diagnosis of ALS.
- Motor neuron diseases (also known as anterior horn cell diseases) are heterogeneous and encompass either upper motor neurons, or lower motor neurons, or both. Upper motor neurons begin in the cerebral cortex and descend into the brainstem (corticobulbar), or spinal cord, where there is a connection to the lower motor neuron that exits the central nervous system and reaches out to the muscle.
  - The various types can be divided into the areas so affected:
    - Amyotrophic lateral sclerosis (Lou Gehrig's disease) – both upper and lower motor neurons
    - Primary lateral sclerosis – upper motor neurons
    - Progressive muscular atrophy – lower motor neurons
    - Progressive bulbar palsy – rare and limited to bulbar muscles (muscles innervated by the cranial nerves – dysarthria and dysphagia)
  - Other rare conditions:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

  - Monomelic amyotrophy (Hirayama disease)
  - Spinal bulbar muscular atrophy (Kennedy disease)
- Signs of lower motor neuron pathology include weakness, fasciculations, atrophy, decreased muscle tone, decreased reflexes, and a plantar extensor response (Babinski sign).
- Signs of upper motor neuron pathology include weakness, increased muscle tone, increased reflexes, and a plantar flexor response.

Evidence Discussion (PN-8.1)

MRI of the Brain and/or Spine is medically necessary to evaluate for amyotrophic lateral sclerosis (ALS)-associated changes as well as evaluation for disorders that may mimic ALS.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Spinal Muscular Atrophy (PN-8.2)

PN.ND.0008.2.A

v1.0.2026

- Molecular genetic testing is the standard tool for diagnosis for the early consideration in any infant with weakness or hypotonia.
  - MRI is **NOT** supported for diagnosis in children unless other diseases are being considered. See **Spinal Muscular Atrophy (PEDPN-5.1)**.
- In individuals with adult-onset disease, the differential includes later-onset motor neuron disorders, such as ALS.
  - For these conditions, advanced imaging is medically necessary when upper and lower motor neuron findings are present. For imaging, see **Motor Neuron Disease/Amyotrophic Lateral Sclerosis (ALS) (PN-8.1)**.

Evidence Discussion (PN-8.2)

- Spinal muscular atrophy (SMA) is a genetic/hereditary disorder. Molecular genetic testing is the standard tool for diagnosis of SMA. MRI is NOT medically necessary for diagnosis of SMA unless other diseases are being considered.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Fasciculations (PN-8.3)

PN.ND.0008.3.A
v1.0.2026

Fasciculations are involuntary, irregular movements of muscle caused by activation of a single motor unit that may be secondary to benign or non-benign etiologies.

- **ALL** of the following evaluations are required prior to advanced imaging:
  - **History and physical exam** should include documentation of the following: time course of symptoms, areas of involvement, weakness, and any associated symptoms such as pain, sensory loss, or bowel or bladder dysfunction.
  - **EMG/NCV evaluation**
  - **Laboratory evaluation** (e.g., complete blood count; comprehensive metabolic panel; serum calcium; thyroid function testing; vitamin B12 level; sed rate; ANA; rheumatoid factor; serum protein electrophoresis with immunofixation; Lyme testing; HIV testing; testing for heavy metals; etc.)

  In the setting of clinical concern for radiculopathy, neuromuscular disorders, or muscle disorders, see the following imaging guidelines:
  - **Neuromuscular Junction Disorders (PN-8.4)**
  - **Muscle Diseases (PN-8.5)**
  - **Neck (Cervical Spine) Pain without and with Neurological Features (Including Stenosis) (SP-3.1)**
  - **Lower Extremity Pain with Neurological Features (Radiculopathy, Radiculitis, or Plexopathy and Neuropathy) with or without Low Back (Lumbar Spine) Pain (SP-6.1)**
- In the presence of upper motor neuron signs (e.g., increased tone; hyperreflexia; presence of Babinski or Hoffman signs) when there is concern for motor neuron disease, including amyotrophic lateral sclerosis (ALS), **ANY** of the following CNS studies are medically necessary:
  - **Brain**: MRI Brain without contrast (CPT® 70551) **or** MRI Brain without and with contrast (CPT® 70553), **AND/OR**
  - **Cervical Spine**: MRI Cervical Spine without contrast (CPT® 72141) **or** MRI Cervical Spine without and with contrast (CPT® 72156), **AND/OR**
  - **Thoracic Spine**: MRI Thoracic Spine without contrast (CPT® 72146) **or** MRI Thoracic Spine without and with contrast (CPT® 72157)
  - See **Motor Neuron Disease/Amyotrophic Lateral Sclerosis (ALS) (PN-8.1)**
- **Lumbar Spine**: Lumbar spine imaging is **NOT** medically necessary unless there is sphincter involvement **or** there is a need to rule out lower motor neuron etiologies in the lower extremities (e.g., lumbar radiculopathy). See the following Spine Imaging Guidelines:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- **Red Flag Indications (SP-1.2)**
- **Lower Extremity Pain with Neurological Features (Radiculopathy, Radiculitis, or Plexopathy and Neuropathy) with or without Low Back (Lumbar Spine) Pain (SP-6.1)**

Evidence Discussion (PN-8.3)

- Fasciculations in isolation are usually benign, especially when they occur repetitively for seconds at a single site and in a single muscle. Fasciculations are more likely to be pathologic if they occur simultaneously in multiple muscles or if they are associated with objective weakness, atrophy, or hyperreflexia.
- Although fasciculations are characteristic of motor neuron disease/amyotrophic lateral sclerosis (MND/ALS) and may occur in other neurological conditions, they are also a very common occurrence in the general population, being noticed by about 70% of normal healthy individuals.
- EMG/NCV evaluation may help differentiate individuals with benign fasciculations from those who warrant further investigation.
- Appropriate laboratory evaluation and imaging would depend on the suspected etiology.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Neuromuscular Junction Disorders (PN-8.4)

PN.ND.0008.4.A
v1.0.2026

Myasthenia Gravis (MG)

- For imaging requests related to ptosis and ocular movements associated with MG, see **Eye Disorders and Visual Loss (HD-32.1)**
- After an established diagnosis of MG or when MG is suspected by a neurologist, rheumatologist, or ophthalmologist, ONE of the following is medically necessary to assess for MG-related thymic disease:
  - CT Chest with contrast (CPT® 71260), **OR**
  - CT Chest without contrast (CPT® 71250), **OR**
  - MRI Chest without and with contrast (CPT® 71552), **OR**
  - MRI Chest without contrast (CPT® 71550)
- Repeat of **ANY ONE** of the above imaging studies is medically necessary if the initial imaging study was negative for **ANY** of the following scenarios:
  - Symptoms of chest mass
  - Rising anti-striated muscle antibody titers
  - Need for pre-operative evaluation (clinical presentation, electro-diagnostic studies, and antibody titers)

Lambert–Eaton Myasthenic Syndrome (LEMS)

Lambert–Eaton myasthenic syndrome (LEMS) is associated with malignancies, especially small cell lung cancer.

- For a suspected diagnosis, **ANY** of the following are medically necessary: CT Chest with contrast (CPT® 71260) **AND/OR** CT Abdomen and Pelvis with contrast (CPT® 74177)
  - See **Paraneoplastic Syndromes (ONC-30.3)**
- If initial CT was negative and there is persistent suspicion, **ANY** of the above imaging studies are medically necessary every 6 months for 2 years from date of initial negative imaging.
  - See **Paraneoplastic Syndromes (ONC-30.3)**

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Stiff-Person Syndrome

Stiff-person syndrome is associated with cancers such as, but not limited to, small cell lung cancer, pancreatic neuroendocrine cancer, and breast cancer.

- If stiff-person syndrome is suspected based on clinical findings, **ANY** of the following are medically necessary:
  - **Abdomen/Pelvis**: CT Abdomen and Pelvis with contrast (CPT® 74177), **or** CT Abdomen and Pelvis without and with contrast (CPT® 74178), **OR** MRI Abdomen without and with contrast (CPT® 74183), **and** MRI Pelvis without and with contrast (CPT® 72197)
  - **Chest**: CT Chest with contrast (CPT® 71260), **or** CT Chest without contrast (CPT® 71250)
  - **Symptomatic Body Areas**: CT with contrast **or** MRI without and with contrast of any other symptomatic body areas
  - See **Paraneoplastic Syndromes (ONC-30.3)**

Background and Supporting Information

- Myasthenia gravis is an autoimmune disease of the neuromuscular junctions, manifested by fatigable weakness of the cranial nerves (examples - ocular: ptosis, diplopia; bulbar: dysphagia, dysarthria, dysphonia), as well as generalized limb weakness, depending on the severity of the disease. Associated antibodies: acetylcholine receptor (AChR), muscle specific kinase (MuSK).
- Lambert Eaton myasthenic syndrome (LEMS) is also an autoimmune disease affecting the neuromuscular junction presenting with ocular and bulbar symptoms and proximal limb weakness. Associated antibodies: P/Q voltage-gated calcium channel (VGCC).
- LEMS can occur as a paraneoplastic syndrome associated with malignancy (cancer-associated LEMS) or as an autoimmune phenomenon in the absence of malignancy (non-tumor LEMS). Between 50% and 60% of all LEMS cases are associated with malignancy, particularly small cell lung carcinoma (SCLC), although LEMS has been described in individuals with non–small cell and mixed-cell lung carcinomas, neuroendocrine tumors such as prostate cancer, thymoma, and lymphoproliferative disorders.
- Stiff-person syndrome is an autoimmune disease associated with muscle spasm and muscle rigidity affecting the trunk and limb muscles. Associated antibodies: Glutamic acid decarboxylase (GAD).

Evidence Discussion (PN-8.4)

- In individuals with myasthenia gravis, advanced chest imaging with CT or MRI is preferred over x-ray for the evaluation of thymic disease and for planned thymectomy.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Lambert-Eaton myasthenic syndrome has been associated with malignancies. Initial and repeat imaging with CT of Chest and/or Abdomen and Pelvis are supported to evaluate for associated cancers, especially small cell lung cancer and neuroendocrine tumors.
- Stiff-person syndrome has been associated with malignancies. Initial and repeat imaging of the chest and/or abdomen and/or pelvis and/or any symptomatic body area with CT Chest and/or CT Abdomen and Pelvis or MRI Abdomen and/or Pelvis and/or CT or MRI of any symptomatic body area are supported to evaluate for associated cancers, such as small cell lung cancer, pancreatic neuroendocrine cancer, and breast cancer.

Muscle Diseases (PN-8.5)

PN.ND.0008.5.A
v1.0.2026

- MRI may be helpful in demonstrating abnormalities in muscles that are difficult to examine or not clinically weak and can help distinguish between different types of muscle disease. MRI is also useful in determining sites for muscle biopsy.

Imaging for Muscle Disease		
Disease	**Indication**	**Imaging**
Any Known or Suspected Muscle Disease	To plan muscle biopsy	Typically an affected muscle is imaged. ◦ Upper Extremity: MRI Upper Extremity Other Than Joint without contrast (CPT® 73218) **OR** MRI Upper Extremity Other Than Joint without and with contrast (CPT® 73220)* **AND/OR** ◦ Lower Extremity: MRI Lower Extremity Other Than Joint without contrast (CPT® 73718) **OR** MRI Lower Extremity Other Than Joint without and with contrast (CPT® 73720)* * When indication column criteria are met, bilateral studies are supported if requested
Myopathy or Myositis	Additional evaluation after clinical exam, EMG/NCV, **OR** labs	
Inflammatory Muscle Diseases ◦ Dermatomyositis ◦ Polymyositis ◦ Inclusion body myositis	◦ Evaluation of differential diagnosis ◦ Selection of biopsy site ◦ Clinical concern for progression ◦ Treatment monitoring ◦ Detection of occult malignancy	

- For interstitial lung disease associated with inflammatory myopathies, see **Interstitial Lung Disease (ILD)/Diffuse Lung Disease (DLD) (CH-11.1)** in the Chest Imaging Guidelines.
- For dermatomyositis and polymyositis with concern for occult neoplasm, see **Paraneoplastic Syndromes (ONC-30.3)** in the Oncology Imaging Guidelines.

Evidence Discussion (PN-8.5)

- MRI is supported in known or suspected muscle disease to identify involved muscle(s). MRI may highlight muscle edema and pathology at the potential biopsy site.[2] MRI is helpful to avoid a false-negative biopsy.
- The ordering of tests should be based on the differential diagnosis arrived at by the history and examination. Laboratory evaluation is often a critical initial step to guide further investigations. Nerve conduction studies and EMG aid in making the diagnosis of neuromuscular disorders and are best conceptualized as extensions of the history and neurologic examination.
- MRI of the affected muscle is supported in the evaluation of individuals with suspected inflammatory myopathy to help identify a reversible etiology such as immune-mediated necrotizing myopathy.
- MRI of affected muscle is supported in the diagnosis and follow-up of individuals with inflammatory myopathies, such as dermatomyositis, polymyositis and inclusion body myositis to identify disease-specific patterns and evaluate response to treatment.
- Inflammatory muscle diseases, including dermatomyositis and polymyositis, have been associated with malignancy. Initial and repeat imaging with CT Chest and/or Abdomen and Pelvis are supported to evaluate for associated cancers, such as adenocarcinomas.

Gaucher Disease (Storage Disorders) (PN-8.6)

PN.ND.0008.6.A
v1.0.2026

Imaging for Gaucher Disease
Initial Imaging: Any or all of the following:
• MRI Lumbar Spine without contrast (CPT® 72148) • Bilateral Femurs with MRI Lower Extremity, Other Than Joint, without contrast (CPT® 73718) • MRI Abdomen without contrast (CPT® 74181) • CT Chest without contrast (CPT® 71250) for individuals with new or worsening pulmonary symptoms
Every 12 months: Any or all of the following:
• To assess treatment response for individuals on enzyme replacement therapy or assess disease progression for individuals in surveillance ◦ MRI Lumbar Spine without contrast (CPT® 72148) ◦ Bilateral Femurs with MRI Lower Extremity, Other Than Joint, without contrast (CPT® 73718) ◦ MRI Abdomen without contrast (CPT® 74181) ◦ CT Chest without contrast (CPT® 71250) for individuals with documented pulmonary involvement
New or worsening pulmonary symptoms
• CT Chest without contrast (CPT® 71250)
Acute bone pain
• An initial X-ray should be obtained ◦ MRI of affected areas with and without contrast if x-ray is non-diagnostic or indicates the need for further imaging, such as equivocal for osteonecrosis, infection, or malignancy

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- PET/CT imaging is considered not medically necessary in the evaluation of Gaucher disease. ^{18}F-FDG does not reliably detect Gaucher disease in the marrow, and other isotopes are not yet FDA-approved for clinical use.

Background and Supporting Information

- Gaucher disease is group of autosomal recessive inborn errors of metabolism characterized by lack of the enzyme acid ß-glucuronidase with destructive ceramide storage in various tissues. Gaucher disease is a treatable disorder (enzyme replacement) in which the liver, spleen, and bone marrow/bones are the most affected organs. Diagnosis is established by decreased enzyme activity or genetic testing.
- Three major types of Gaucher disease are recognized:
  - **Type I** (non-neuropathic form or adult form): progressive hepatomegaly, splenomegaly, anemia and thrombocytopenia, and marked skeletal involvement; lungs and kidneys may also be involved, but central nervous system is spared
  - **Type II** (acute neuropathic form or infantile form): severe progressive neurological involvement and death by 2 to 4 years of age; hepatomegaly and splenomegaly are also present (usually evident by 6 months of age)
  - **Type III**: type I with neurological involvement and slowly progressive disease. Onset may be present before 2 years of age with survival to the third or fourth decade of life.
- Additionally, there is a perinatal-lethal and a cardiovascular form. The cardiovascular form involves the heart, spleen and eyes. Note that cardiopulmonary complications may be present, with varying frequency and severity, in all subtypes.
- Individuals with Gaucher disease are at risk for osteonecrosis, osteomyelitis, and bony tumors

Evidence Discussion (PN-8.6)

- Initial imaging and lifelong re-imaging is supported due to Gaucher disease's progressive, multisystem involvement.
- Due to bone involvement, including increased risk for multiple myeloma, skeletal x-rays, MRI of Lumbar Spine and MRI Bilateral Femurs are supported. Delineating the extent of disease can have a positive impact on developing appropriate treatment strategies.
- CT is the preferred study for the evaluation of lung parenchyma and is supported to evaluate for pulmonary involvement.
- MRI Abdomen is supported to evaluate for associated visceral disease, such as hepatic, splenic and biliary disease. This modality has better signal-to noise-ratio and soft tissue contrast helping to make more precise diagnosis.
- The role of PET/CT imaging in Gaucher disease is yet to be established. In the absence of malignancy, PET/CT is not considered medically necessary in the

Peripheral Nerve Sheath Tumors (PNST) (PN-9.1)

PN.NS.0009.1.A
v1.0.2026

PNST such as Schwannomas or neurofibromas arise from Schwann cells or other connective tissue of the nerve. They can be located anywhere in the body.

When Peripheral Nerve Sheath Tumors (PNST) is suspected, the following advanced imaging is medically necessary:	
Suspected Lesion/Indication	**Imaging**
Vestibular Schwannoma	• MRI Brain without and with contrast (CPT® 70553) See **Acoustic Neuroma and Other Cerebellopontine Angle Tumors (HD-33.1)** in the Head Imaging Guidelines
Paraspinal Neurofibroma	**ANY** of the following imaging: • MRI Cervical Spine without and with contrast (CPT® 72156), **AND/OR** • MRI Thoracic Spine without and with contrast (CPT® 72157), **AND/OR** • MRI Lumbar Spine without and with contrast (CPT® 72158)
Neurofibroma of the Limb or Torso (other than Paraspinal)	• MRI without and with contrast or without contrast of the area of interest after plain x-ray* ◦ See **Soft Tissue Mass (MS-10.1)** in the Musculoskeletal Imaging Guidelines *Plain x-ray is not required in an individual with a cancer predisposition syndrome. • See **Screening Imaging in Cancer Predisposition Syndromes (PEDONC-2)** in the Pediatric and Special Populations Oncology Imaging Guidelines

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Routine follow-up imaging is NOT indicated *except in the following scenarios:*	
Suspected Lesion/Indication	**Imaging**
New symptoms or neurological findings	• MRI without and with contrast of the known body area containing PNST
Post-operatively for ANY of the following scenarios: • At the discretion of or in consultation with the surgeon; • If the tumor was not completely removed and the imaging is requested to re-establish baseline	• MRI without and with contrast of the known body area containing PNST or from which PNST was removed
Request for metastatic work-up when malignant transformation is known or suspected	**ANY** of the following imaging: • CT Chest with contrast (CPT® 71260) **AND/OR** • CT Abdomen with contrast (CPT® 74160)

- For guidelines related to known malignancies in individuals with neurofibromatosis 1 (NF1), see the appropriate imaging guideline for the specific cancer type.

Background and Supporting Information

- The role of PET imaging in peripheral nerve sheath tumors is not yet well established.
- Malignant transformation may be present in approximately 5% of peripheral nerve sheath tumors.

Evidence Discussion (PN-9.1)

- Peripheral nerve sheath tumors (PNSTs) may arise from any body region. PNSTs are susceptible to malignant transformation. Therefore, MRI of the known or suspected body region is supported for evaluation.
- MRI is the preferred imaging modality for soft tissue tumors, such as PNSTs, and is a relatively safe imaging modality since radiation exposure is not involved. The role of PET imaging in peripheral nerve sheath tumors is not yet well established. Otherwise, PET imaging in this clinical scenario would not add any clinical value and would unnecessarily expose individuals to radiation.

Nuclear Imaging (PN-10.1)

PN.NI.0010.1.A
v1.0.2026

- Nuclear Medicine
  - Nuclear medicine studies are **NOT** medically necessary in the evaluation of peripheral nerve disorders.

Evidence Discussion (PN-10)

- Though PET has well established roles in disorders other than peripheral neuropathies, the resolution of PET is on the order of millimeters, which limits its usefulness in evaluation of peripheral nerve disorders. As a result, PET may be most useful for nerve injury in combination with higher resolution structural imaging such as MRI.
- Fusion PET/MRI's role in peripheral nerve injuries is less defined and still largely limited to animal studies as an alternative non-invasive diagnostic modality.
- At this time, the use of PET/MRI for peripheral nerve disease is considered not medically necessary.

Abbreviations and Glossary for the PVD Imaging Guidelines

v2.0.2026

(See also:Cardiac Imaging Guidelines Glossary)

AAA	Abdominal aortic aneurysm
ABI	Ankle brachial index: a noninvasive, non-imaging test for arterial insufficiency – (see toe-brachial index below). This testing can also be done after exercise if resting results are normal.
Claudication or intermittent claudication	usually a painful cramping sensation of the legs with walking or severe leg fatigue
CLI	Critical Limb Ischemia
CTA	Computed tomography angiography
CTV	Computed tomography venography
DLCO	Diffusion capacity: defined as the volume of carbon monoxide transferred into the blood per minute per mmHg of carbon monoxide partial pressure
DVT	Deep venous thrombosis
ECG	Electrocardiogram
ENT	Ears, Nose, Throat
EVAR	Endovascular Aneurysm Repair
HbA1C	Hemoglobin A1C: test used to determine blood sugar control for individuals with diabetes
MRA	Magnetic resonance angiography

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

MRV	Magnetic resonance venography
PAD	Peripheral artery disease
PAH	Pulmonary artery hypertension
PFT	Pulmonary function tests
PVD	Peripheral vascular disease
PSV ratio	Peak systolic velocities
SVC	Superior vena cava
TEVAR	Thoracic Endovascular Aortic Repair
TIA	Transient ischemic attack
TTE	Transthoracic echocardiogram
Toe-Brachial Index	Useful in individuals with ABI above the normal range due to non-compressible posterior tibial or dorsalis pedis arteries
V/Q Scan	Ventilation and perfusion scan

Proprietary Information of UnitedHealthcare.

General Guidelines (PVD-1.0)

PVD.GG.0001.0.A
v2.0.2026

General Guidelines

- Prior to considering advanced imaging, a pertinent clinical evaluation or meaningful technological contact performed since the symptoms began or worsened is required describing any relevant medical treatments and a vascular history and physical that includes (when applicable):
  - Palpation of pulses
  - Evaluation of lower extremities for presence of non-healing wounds or gangrene
  - Associated skin changes such as thickened nails, absence of hair in the feet or calves, cool extremities
  - Evaluation for the presence of arterial bruits
  - Appropriate laboratory studies
  - Non-advanced imaging modalities, such as recent ABIs, venous duplex or venous valvular insufficiency study (VVI) performed after symptoms started or worsened
  - The affected limb(s), the extent of the edema (calf and/or thigh), pitting or non-pitting. With regard to venous insufficiency, presence or absence of hyperpigmentation or other skin changes, ulcerations if applicable, size of varicosities if present as well as distribution
  - Arterial examination to rule out phlegmasia alba/cerulea dolens which is compromised arterial flow secondary to extensive DVT if applicable
  - Appropriate laboratory studies, for example d-dimer, if applicable
- Arterial- ABI should be measured first:
  - If normal, then further vascular studies are generally not indicated.
  - If clinical suspicion for PAD remains high with normal ABI's, exercise ABI's (CPT® 93924) can be performed on a treadmill to elicit ischemia
  - The TBI (toe-brachial index) is used to establish the diagnosis of PAD in the setting of non-compressible arteries (ABI ≥1.40) and may also be used to assess perfusion in individuals with suspected CLI (rest pain and/or non-healing wound)
- If a prior imaging study (Ultrasound, MRA, CTA, Catheter angiogram, etc.) has been completed for a condition, a follow-up, additional, or repeat study for the same condition is generally not medically necessary unless there has been a change in the individual's condition, previous imaging showed an indeterminate finding, or condition specific sections in these guidelines support routine follow-up imaging.

Click Here to Return to the Main TOC

- Runoff studies (CPT® 75635 for CTA or CPT® 74185, CPT® 73725, and CPT® 73725 for MRA) image from the umbilicus to the feet
  - CTA Abdomen and lower extremities should be reported as CPT® 75635, rather than using the individual CPT® codes for the abdomen, pelvis, and legs
  - MRA Abdomen, MRA Pelvis and MRA Lower extremities should be reported as CPT® 74185, CPT® 73725, and CPT® 73725. The CPT® code for MRA Pelvis (CPT® 72198) should not be included in this circumstance.
- CTA Head and Neck should be reported as CPT® 70471, rather than using the individual codes for the CTA Head and CTA Neck.
- Venous-imaging
  - Venous duplex (CPT® 93970, CPT® 93971) of the limb is the initial imaging of choice.
  - Follow-up duplex imaging is not medically necessary to document resolution and should only be obtained for new signs/symptoms or for concerns of propagation of thrombus when the treatment plan would change (insertion of IVC filter, change of anticoagulation, etc.)

Evidence Discussion

Venous duplex should visualize the veins, with demonstration of the presence or absence of compressibility and venous flow. Venous valvular insufficiency studies visualize the veins of the lower extremity, assess for reflux (reversal of venous antegrade flow after valve closure) and measure its duration. CTV or MRV Abdomen and Pelvis images with contrast involves taking images from the diaphragm to just below the inguinal ligament after a delay of a few minutes after IV contrast is administered to optimize filling and therefore visualization of the venous vasculature.

Venous disease can be classified into three categories:

- Veno-occlusive disease
  - Types of thrombotic disease
    - Superficial venous thrombosis
    - Deep venous thrombosis
    - Iliac vein obstruction, unilateral or bilateral
    - May-Thurner syndrome
  - Signs/Symptoms of veno-occlusive disease is generally sudden onset of pain and edema in the limb.
  - Risk factors include age >40, obesity, pregnancy, prolonged immobility, post-surgery, and malignancy among others.
  - Procedures related to veno-occlusive disease include:
    - Thrombolysis
    - Thrombectomy

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

        - Post-iliac vein stent/angioplasty
- Venous insufficiency
    - Types of venous insufficiency:
        - Superficial and deep venous reflux
        - Varicose veins
        - Reticular and spider veins.
    - Signs/symptoms of venous insufficiency include:
        - Chronic swelling in the leg that is relieved with elevation
        - Chronic swelling in the leg that is worse in the evenings
        - Aching or sense of heaviness in the leg
        - Hyperpigmentation of the calf particularly around the ankle
        - Itchy skin on legs and feet
        - Leather appearance of the skin of the calves
        - Skin ulcers in the calf particularly around the medial malleolus
        - Varicose veins
        - Spider veins/reticular veins/telangiectasias
    - Procedures related to the venous insufficiency include:
        - Endovenous laser ablation utilizing either chemical, laser or radio-frequency
        - Saphenous vein high ligation and stripping
        - Phlebectomy, stab or powered
        - Sclerotherapy, liquid or foam
- Venous malformations
    - Types of venous malformations include:
        - Arterio-venous malformations which can occur throughout the body
        - See **Pulmonary AVM (CH-24)** in the Chest imaging guidelines
        - See **Aneurysm and AVM (HD-12)** in the Head imaging guidelines
        - See **Pelvic Pain/Dyspareunia (PV-11)** in the Pelvic imaging guidelines
        - Klippel-Trenaunay which affects primarily the lower extremity venous circulation and is characterized by varicose veins, limb size discrepancies, and port-wine stains.
    - Treatment includes:
        - Primarily embolization
        - Sclerotherapy
            - Klippel-Trenaunay: treatment can include phlebectomy and sclerotherapy of symptomatic varicose veins provided they meet the criteria for intervention.

General Information

- Risk factors for vascular disease include:
  - Diabetes
  - Cigarette smoking
  - Hypertension
  - Hyperlipidemia
  - Age >50, with at least one risk factor, are considered “at risk” for vascular disease
  - See also: **Impotence/Erectile Dysfunction (PV-17)** in the Pelvis Imaging Guidelines.
- Signs and symptoms of peripheral arterial disease
  - Claudication (Cramping pain in the legs, most notably back of the calves but can involve hips or thighs, after walking which is relieved with rest but recurs at a predictable distance)
    - Symptoms that are not consistent with claudication include
      - Generalized leg pain
      - Nocturnal cramps
      - Pain that is not easily relieved after a few minutes of rest
      - Burning pain in feet
  - Critical limb ischemia
    - Rest pain: Pain in the foot (not leg) at rest, particularly at night when the leg is elevated. Pain is relieved by dangling the leg off the bed or moving to an upright position
    - Non-healing wounds: Wounds present for >2 weeks with little to no evidence of healing
  - Erectile dysfunction can be associated with vascular disease
- Claudication and critical limb ischemia have different natural histories. Claudication generally follows a benign indolent course. 70% of individuals with claudication will have the same symptoms after five years with no progression. Critical limb ischemia, on the other hand, is associated with a high rate of limb loss (25%) and death (35%) one year after presentation
- Simultaneous venous and arterial systems evaluation are unusual but are occasionally needed
- Post-angioplasty/reconstruction: follow-up imaging is principally guided by symptoms. See also:
  - **Post Aortic Endovascular/Open Surgery Surveillance Studies (PVD-6.8)**
  - **Post-procedure Surveillance Studies (PVD-7.3)**

General Guidelines – Imaging

- Imaging Studies:
  - Carotid studies MRA Neck (CPT® 70543) or CTA Neck (CPT® 70491) capture the area from the top of the aortic arch (includes the origin of the innominate artery, common carotid artery, and subclavian artery, which gives off the vertebral artery) to the base of the skull.
  - CTA or MRA Abdomen (CPT® 74175 or CPT® 74185) images from the diaphragm to the umbilicus or iliac crest
  - CTA or MRA Chest (CPT® 71275 or CPT® 71555) images from the base of the neck to the dome of the liver
  - Runoff studies (CPT® 75635 for CTA or CPT® 74185, CPT® 73725, and CPT® 73725 for MRA) image from the umbilicus to the feet
    - CTA Abdomen and lower extremities should be reported as CPT® 75635, rather than using the individual CPT® codes for the abdomen, pelvis, and legs
    - MRA Abdomen, MRA Pelvis and MRA Lower extremities should be reported as CPT® 74185, CPT® 73725, and CPT® 73725. The CPT® code for MRA Pelvis (CPT® 72198) should not be included in this circumstance

Quantification of plaque morphology

CPT® 0710T, CPT® 0711T, CPT® 0712T, CPT® 0713T

There is insufficient evidence to support the routine use of data from non-coronary computed tomography angiography (CTA) to quantify plaque morphology in noncoronary vessels. These studies are considered experimental, investigational, or unproven.[1]

Procedure Coding

Non-invasive Physiologic Studies of Extremity Arteries	CPT®
• Limited bilateral noninvasive physiologic studies of upper or lower extremity arteries. • Non-invasive physiologic studies of upper or lower extremity arteries, single level, bilateral (e.g. ankle/brachial indices, Doppler waveform analysis, volume plethysmography, transcutaneous oxygen tension measurement).	93922

[1] Guo Z, Liu Y, Xu J, et al. A deep learning model for carotid plaques detection based on CTA images: a two stepwise early-stage clinical validation study. Front Neurol. 2025;15:1480792. doi:10.3389/fneur.2024.1480792.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Non-invasive Physiologic Studies of Extremity Arteries	CPT®
• Complete bilateral noninvasive physiologic studies of upper or lower extremity arteries, 3 or more levels. • Non-invasive physiologic studies of upper or lower extremity arteries, multiple levels or with provocative functional maneuvers, complete bilateral study (e.g., segmental blood pressure measurements, segmental Doppler waveform analysis, segmental volume plethysmography, segmental transcutaneous oxygen tension measurements, measurements with postural provocative tests, measurements with reactive hyperemia).	93923

- CPT® 93922 and CPT® 93923 can be requested and reported only once for the upper extremities and once for the lower extremities.
- CPT® 93922 and CPT® 93923 should not be ordered on the same request nor billed together for the same date of service.
- CPT® 93924 and CPT® 93922 and/or CPT® 93923 should not be ordered on the same request and should not be billed together for the same date of service.
- ABI studies performed with handheld doppler, where there is no hard copy output for evaluation of bidirectional blood flow, is not reportable by these codes.

Non-invasive Physiologic Studies of Extremity Arteries	CPT®
Non-invasive physiologic studies of lower extremity arteries, at rest and following treadmill stress testing, complete bilateral study.	93924

Arterial Duplex – Upper and Lower Extremities	CPT®
Duplex scan of lower extremity arteries or arterial bypass grafts; complete bilateral.	93925
• A complete duplex scan of the lower extremity arteries includes examination of the full length of the common femoral, superficial femoral and popliteal arteries. • The iliac, deep femoral, and tibioperoneal arteries may also be examined.	
Duplex scan of lower extremity arteries or arterial bypass grafts; unilateral or limited study.	93926
• The limited study is reported when only one extremity is examined or when less than a full examination is performed (e.g. only one or two vessels or follow-up).	

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Arterial Duplex – Upper and Lower Extremities	CPT®
Duplex scan of upper extremity arteries or arterial bypass grafts; complete bilateral.	93930
• A complete duplex of the upper extremity arteries includes examination of the subclavian, axillary, and brachial arteries. • The radial and ulnar arteries may also be included.	
Duplex scan of upper extremity arteries or arterial bypass grafts; unilateral or limited study.	93931
• The limited study is reported when only one extremity is examined or when less than a full examination is performed (e.g. only one or two vessels or follow-up).	

Cerebrovascular Artery Studies	CPT®
Duplex scan of extracranial arteries; complete bilateral study.	93880
Duplex scan of extracranial arteries; unilateral or limited study.	93882
• This study is often referred to as a “carotid ultrasound” or “carotid duplex”. • Typically, it includes evaluation of the common, internal, and external carotid arteries.	

Transcranial Doppler Studies	CPT®
Transcranial Doppler study of the intracranial arteries; complete study	93886
Transcranial Doppler study of the intracranial arteries; limited study	93888
Transcranial Doppler vasoreactivity study	93890
Transcranial Doppler study of the intracranial arteries; emboli detection without intravenous microbubble injection	93892
Transcranial Doppler study of the intracranial arteries; emboli detection with intravenous microbubble injection	93893

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Venous Studies- Extremities	CPT®
Duplex scan of extremity veins, including responses to compression and other maneuvers; complete bilateral study.	93970
Duplex scan of extremity veins, including responses to compression and other maneuvers; unilateral or limited study.	93971
• These codes are used to report studies of lower or upper extremity veins. • A complete bilateral study of the lower extremity veins includes examination of the common femoral, proximal deep femoral, great saphenous and popliteal veins. Calf veins may also be included. • A complete bilateral study of upper extremity veins includes examination of the subclavian, jugular, axillary, brachial, basilica, and cephalic veins. Forearm veins may also be included.	

Visceral Vascular Studies	CPT®
Duplex scan of arterial inflow and venous outflow of abdominal, pelvic, scrotal contents and/or retroperitoneal organs; complete study.	93975
Duplex scan of arterial inflow and venous outflow of abdominal, pelvic, scrotal contents and/or retroperitoneal organs; limited study	93976
Duplex scan of aorta, inferior vena cava, iliac vasculature, or bypass grafts; complete study	93978
Duplex scan of aorta, inferior vena cava, iliac vasculature, or bypass grafts; unilateral or limited study	93979

Duplex for Hemodialysis Access	CPT®
Duplex scan of hemodialysis access (including arterial inflow, body of access and venous outflow).	93990
Duplex scan of arterial inflow and venous outflow for preoperative vessel assessment prior to creation of hemodialysis access; complete bilateral study	93985

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Duplex for Hemodialysis Access	CPT®
Duplex scan of arterial inflow and venous outflow for preoperative vessel assessment prior to creation of hemodialysis access; complete unilateral study	93986

Nuclear Medicine Imaging Indications

- Nuclear medicine studies are rarely used in the evaluation of peripheral vascular disorders but are considered medically necessary in the following circumstances:
  - Lymphoscintigraphy (CPT® 78195) for evaluation of lower extremity lymphedema when recent Doppler ultrasound of the lower extremity and abdomen are negative for valvular insufficiency.
  - Indium 111 (^{111}In)–labeled white blood cell (WBC) or Gallium-67 citrate studies (CPT® 78800, CPT® 78801, CPT® 78802, or CPT® 78803) for evaluation of **any** of the following:
    - Mycotic aneurysms.
    - Vascular graft infection.
    - Infection of central venous catheter or other indwelling device.
  - PET/CT (CPT® 78815) for clinical suspicion of aortic infection (graft or native aorta) when **both** of the following apply:
    - CT-angiogram is equivocal/indeterminate AND
    - Indium-111 or Gallium-67 studies have not been performed **and** are not available or not technically feasible.

Non-indications

Evidence does not support routine use of these studies for peripheral vascular evaluation. MRA, CTA, and duplex ultrasonography provide superior diagnostic value more likely to impact clinical management. Therefore, these studies are considered not medically necessary for any peripheral vascular imaging indication:

- Venous thrombosis imaging (CPT® 78456, CPT® 78457, and CPT® 75458)
- Vascular flow imaging (CPT® 78445)

Health Equity Considerations

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

Screening for Peripheral Artery / Aneurysmal Disease (PVD-2)

PVD.GP.0002.A
v2.0.2026

Asymptomatic Screening (PVD-2.1)

- Routine screening of asymptomatic individuals for PAD is not medically necessary. Those with CVD risk factors should be placed on best medical management and should be questioned on symptoms of PAD at annual physicals.
- Currently, there is no evidence to demonstrate that screening all individuals with PAD for asymptomatic atherosclerosis in other arterial beds improves clinical outcome.
- Resting ABI's may be medically necessary in individuals with abnormal pulse exams.
- Screening in the presence of aortic aneurysms:
  - In an individual with a known TAA, screening for AAA is medically necessary with an abdominal duplex. See **Abdominal Aortic Aneurysm (AAA) (PVD-6.3)**
  - In an individual with a known AAA, screening for TAA is not supported by sufficient evidence and is not considered medically necessary.

Evidence Discussion

Screening for Suspected Peripheral Artery Disease/Aneurysmal Disease

Generally, routine screening for peripheral arterial disease in asymptomatic patients is not cost-effective and has not been shown to improve patient outcomes. There are some familial and genetic conditions that may predispose individuals to aneurysmal disease and dissection. In these cases, surveillance imaging has been shown to improve early detection and intervention when indicated. Conditions that may have an elevated risk for vascular disease include:

- Familial Aneurysm Syndromes
- Fibromuscular Dysplasia
- Spontaneous Coronary Artery Dissection (SCAD)
- Ehlers-Danlos
- Marfan
- Loeys-Dietz

In the case of aneurysms detected in patients with SCAD, Marfan, Loeys-Dietz and Ehlers-Danlos Type IV syndromes, a more frequent surveillance pattern along with additional anatomic region imaging may be indicated as these syndromes

demonstrate a higher incidence of aneurysm development and degeneration. Intervention recommendations follow general guidelines for thoracic aortic, abdominal aortic and visceral artery aneurysms once detected.

While duplex imaging remains an effective modality for abdominal aortic surveillance, these conditions often involve the thoracic aorta as well as cerebrovascular and visceral vessel abnormalities that may be technically limited with this approach. Due to the high incidence of aneurysm development in multiple anatomic locations, CT/MR imaging is recommended for surveillance in this population for cases with indeterminate ultrasound imaging.

There is an association between bicuspid aortic valve and thoracic aneurysm development. Individuals diagnosed with this condition should undergo screening and follow standard surveillance patterns using CT/MR of the chest as well as echocardiography should a thoracic aortic aneurysm be detected. The addition of cardiac-specific CT/MR has not shown benefit in these cases as the pathology is usually noted within the aorta.

Multisystemic Smooth Muscle Syndrome [MSMS], Smooth Muscle Dysfunction Syndrome [SMDS] and ACATA2 mutations have a high incidence of aneurysm development early in life and should undergo screening and routine surveillance after genetic confirmation. To minimize radiation exposure in this pediatric population, MR and ultrasound imaging are recommended when possible.

Screening for Vascular related genetic connective tissue Disorders (PVD-2.2)

Vascular related genetic connective tissue Disorders include:

- Familial Aneurysm Syndromes
- Fibromuscular Dysplasia
- Spontaneous Coronary Artery Dissection (SCAD)
- Ehlers-Danlos
- Marfan
- Loeys-Dietz

Description	CPT®
70496	Computed tomographic angiography, head, with contrast material(s), including noncontrast images, if performed, and image postprocessing
70498	Computed tomographic angiography, neck, with contrast material(s), including noncontrast images, if performed, and image postprocessing
70471	Computed tomographic angiography (CTA), head and neck, with contrast material(s), including noncontrast images, when performed, and image postprocessing
72198	Magnetic resonance angiography, pelvis, with or without contrast material(s)
74174	Computed tomographic angiography, abdomen and pelvis, with contrast material(s), including noncontrast images, if performed, and image postprocessing
74185	Magnetic resonance angiography, abdomen, with or without contrast material(s)
70544	Magnetic resonance angiography, head; without contrast material(s)
70545	Magnetic resonance angiography, head; with contrast material(s)
70546	Magnetic resonance angiography, head; without contrast material(s), followed by contrast material(s) and further sequences
70548	Magnetic resonance angiography, neck; with contrast material(s)
70549	Magnetic resonance angiography, neck; without contrast material(s), followed by contrast material(s) and further sequences

Screening and initial diagnosis

- Screening for Familial Syndromes is medically necessary in individuals with a positive family history (1st degree relative with dissection/TAA) but no known genetic

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

syndrome/mutation, otherwise known as Suspected Familial Aneurysm Syndrome as follows:
  - ECHO (CPT® 93306, CPT® 93307, or CPT® 93308) and chest x-ray for all First-degree relatives (parents, siblings, children) of individuals with TAA and/or dissection.
  - Any imaging listed in the **Table of Thoracic Aorta Imaging Options** is medically necessary if these studies identify a TAA or are equivocal or do not visualize the ascending or descending aorta adequately.
  - Studies can be repeated at 2 year intervals if prior results are negative
- Initial imaging for individuals with documented SCAD/fibromuscular dysplasia/Marfan/ Loeys-Dietz/Ehlers-Danlos type IV is medically necessary as follows:
  - On initial diagnosis of Ehlers-Danlos, Loeys-Dietz, Marfan, SCAD, or suspicion of fibromuscular dysplasia, full vascular imaging from head to pelvis with:
    - CTA or MRA Head (and/or MRA Neck or CTA Head and Neck or CTA Head or CTA Neck
    - CTA or MRA Chest or CT Chest with contrast
    - CTA Abdomen/Pelvis or MRA Abdomen/Pelvis or (
  - If there are no identified aneurysms or dissections, repeat imaging can be obtained at two-year intervals

Surveillance

Surveillance imaging
- If an aneurysm is identified in individuals with fibromuscular dysplasia, then the aneurysm can be surveilled per the typical time-frame as described in **Thoracic Aortic Aneurysm (TAA) (PVD-6.2)**, **Abdominal Aortic Aneurysm (AAA) (PVD-6.3)**, **Iliac Artery Aneurysm (IAA) (PVD-6.4)**, and **Visceral Artery Aneurysm (PVD-6.5)**.
- Follow-up of aneurysms in individuals with documented SCAD/Marfan/Loeys-Dietz/ Ehlers-Danlos type IV
  - Imaging is medically necessary every 6 months once an aneurysm has been identified until a decision has been made to repair.
    - Intracranial aneurysm – CTA or MRA Head (
    - Aneurysm of a cervical artery – Carotid duplex or CTA or MRA neck if unable to fully visualize with carotid duplex
    - Thoracic aorta – CTA Chest or CT Chest with contrast or without , MRA chest
    - Abdominal aneurysm – Abdominal duplex (CPT® 93975/93976/93978/93979/76770/76775)
    - Visceral aneurysm – These can be difficult to visualize on duplex. If not visible on duplex, can obtain a CTA or MRA Abdomen and Pelvis.

Background and Supporting Information

Fibromuscular dysplasia and spontaneous coronary artery dissection is diagnosed radiographically. Loeys-Dietz, Marfan, Ehlers-Danlos type IV are diagnosed with genetic testing.

Evidence Discussion

Screening for Vascular Related Genetic Connective Tissue Disorders

Generally, routine screening for peripheral arterial disease in asymptomatic patients is not cost-effective and has not been shown to improve patient outcomes. There are some familial and genetic conditions that may predispose individuals to aneurysmal disease and dissection. In these cases, surveillance imaging has been shown to improve early detection and intervention when indicated. Conditions that may have an elevated risk for vascular disease include:

- Familial Aneurysm Syndromes
- Fibromuscular Dysplasia
- Spontaneous Coronary Artery Dissection (SCAD)
- Ehlers-Danlos
- Marfan
- Loeys-Dietz

In the case of aneurysms detected in patients with SCAD, Marfan, Loeys-Dietz and Ehlers-Danlos Type IV syndromes, a more frequent surveillance pattern along with additional anatomic region imaging may be indicated as these syndromes demonstrate a higher incidence of aneurysm development and degeneration.[4,5] Intervention recommendations follow general guidelines for thoracic aortic, abdominal aortic and visceral artery aneurysms once detected.

While duplex imaging remains an effective modality for abdominal aortic surveillance, these conditions often involve the thoracic aorta as well as cerebrovascular and visceral vessel abnormalities that may be technically limited with this approach. Due to the high incidence of aneurysm development in multiple anatomic locations, CT/MR imaging is recommended for surveillance in this population for cases with indeterminate ultrasound imaging.

Screening for TAA with bicuspid aortic valves (PVD-2.3)

Table of Thoracic Aorta Imaging Options

CPT®	Description
71250	Computed tomography, thorax, diagnostic; without contrast material
71260	Computed tomography, thorax, diagnostic; with contrast material(s)
71275	Computed tomographic angiography, chest (noncoronary), with contrast material(s), including noncontrast images, if performed, and image postprocessing
71555	Magnetic resonance angiography, chest (excluding myocardium), with or without contrast material(s)
93306	Transthoracic echocardiogram

Indications

Screening

- Screening is medically necessary in individuals with bicuspid aortic valve:
  - Screening, any requested imaging from the **Table of Thoracic Aorta Imaging Options** and/or ECHO (CPT® 93306, CPT® 93307, or CPT® 93308).
    - There is no evidence-based data to support screening relatives of individuals with bicuspid aortic valve for TAA except with echocardiogram.
  - Follow-up per TAA Follow-up guidelines in **Thoracic Aortic Aneurysm (TAA) (PVD-6.2)**

Surveillance

If no dilatation of the aortic root or ascending thoracic aorta is found, there is no evidence-based data to support the medical necessity of continued surveillance imaging

Evidence Discussion

Screening for TAA with Bicuspid Aortic Valves

There is an association between bicuspid aortic valve and thoracic aneurysm development. Individuals diagnosed with this condition should undergo screening and follow standard surveillance patterns using CT/MR of the chest as well as echocardiography should a thoracic aortic aneurysm be detected. The addition of cardiac-specific CT/MR has not shown benefit in these cases as the pathology is usually noted within the aorta. If negative for bicuspid valve pathology, additional surveillance imaging is not been supported.

Screening for Vascular Related Disorders in ACTA2 Mutations (PVD 2.4)

Screening for Vascular Related Disorders in Multisystemic Smooth Muscle Syndrome (MSMS)/Smooth Muscle Dysfunction Syndrome (SMDS)/ACTA2 Mutations

Initial imaging

Upon initial genetic confirmation, all of the following studies are medically necessary:

- Transthoracic echocardiogram (TTE)
- MRA Chest or CTA Chest and CT Chest with contrast
- MRA Abdomen and Pelvis (CPT® 74185 and 72198) or CTA Abdomen and Pelvis (CPT® 74174)
- MRI Perfusion study Brain CPT® 70553
- MRA Head and Neck (CPT® 70544 or 70545 AND 70548)
- Ultrasound Upper extremity(ies) (CPT® 93930 or 93931) or CTA Upper extremity (CPT® 73206) or MRA Upper extremity (CPT® 73225)

Repeat testing

Repeat testing with any of the studies listed under initial imaging is medically necessary when there is documentation of new signs or symptoms.

Surveillance imaging

Surveillance imaging with any of the studies listed in initial imaging is medically necessary according to the following:

- Transthoracic echocardiogram repeat every 6 months
- Chest imaging can be repeated every 12 months starting at age 10
- Abdomen and pelvis imaging can be repeated every 12 months starting age 10
- Upper extremity imaging can be repeated every 12 months starting age 10
- MRI perfusion study Brain see **Dysfunction Syndrome (SMDS)/ACTA2 Mutations (PEDHD-12.8)**
- MRA Head and Neck see **Dysfunction Syndrome (SMDS)/ACTA2 Mutations (PEDHD-12.8)**

Background and Supporting Information

Smooth Muscle Dysfunction Syndrome presents as congenital mydriasis, a patent ductus arteriosus (PDA), pulmonary arterial hypertension (PAH) during infancy. Patients go on to developed aortic, peripheral arterial, and cerebrovascular disorders in childhood.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Caused by heterozygous mutation of ACTA2. P.Arg179His
- Cases mostly due to de novo mutations, so imaging screening based on family history without genetic confirmation is not supported.
- Because radiation is a known risk factor for moyamoya disease. MRI/MRA Head is recommended instead of Computed Tomography (CT)/CTA

Evidence Discussion

Screening for Vascular Related Disorders in Multisystemic Smooth Muscle Syndrome (MSMS)/Smooth Muscle Dysfunction Syndrome (SMDS)/ACTA2 Mutations

Multisystemic Smooth Muscle Syndrome [MSMS], Smooth Muscle Dysfunction Syndrome [SMDS] and ACATA2 mutations have a high incidence of aneurysm development early in life and should undergo screening and routine surveillance after genetic confirmation. To minimize radiation exposure in this pediatric population, MR and ultrasound imaging are recommended when possible.

70545	Magnetic resonance angiography, head; with contrast material(s)

- Duplex ultrasound (CPT® 93880 bilateral or CPT® 93882 unilateral) is medically necessary to evaluate possible carotid artery disease, prior to considering advanced imaging, when ANY of the following apply:
  - Known or suspected retinal arterial emboli or Hollenhorst plaque
  - Pulsatile neck masses
  - Carotid or cervical bruit
  - Abnormal findings on physical exam of the carotid arteries (e.g., absent carotid pulses)
  - Preoperative evaluation of individuals with evidence of severe diffuse atherosclerosis, scheduled for major cardiovascular surgical procedures
  - Preoperative evaluation of individuals prior to elective cardiovascular surgery in individuals older than 65 years of age and in those with peripheral artery disease, history of cigarette smoking, history of stroke or TIA, or carotid bruit

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

  - Suspected Subclavian Steal Syndrome for additional imaging see **Upper Extremity PVD – Imaging (PVD-4.1)**
  - Blunt neck trauma in the absence of focal neurological symptoms
  - Neurologic complaints after chiropractic neck manipulation
  - Vasculitis potentially involving carotid arteries, such as Takayasu's arteritis and fibromuscular dysplasia (FMD)
  - Remote history of stroke or TIA (Greater than one month).
- CTA or MRA Neck is medically necessary to evaluate suspected internal carotid artery dissection, in individuals with **any** of the following mechanisms of injury or risk factors for arterial dissection:
  - Chiropractic manipulation of neck
  - Whiplash injury
  - Fibromuscular dysplasia/Marfan
  - Stroke in the young (age ≤50)
- CTA or MRA Neck is medically necessary to evaluate suspected vertebrobasilar pathology:
  - Symptoms include:
    - Vertigo associated with nausea and vomiting
    - Diplopia
    - Loss of vision in one or both eyes
    - Dysarthria
    - Bifacial numbness
    - Bilateral extremity weakness and/or numbness
    - Acute changes in mental status
    - Loss of consciousness
    - Ataxia
  - MRA or CTA of **both** Neck and Head are required to visualize the entire vertebral-basilar system for evaluation of posterior circulation disease.
  - Surveillance imaging, post-stenting or known vertebrobasilar disease, interval determined by Vascular Specialist, Neurologist, or Neurosurgeon or any provider in consultation with a vascular specialist, neurologist, or neurosurgeon for ANY of the following:
    - Asymptomatic
    - Unchanged symptoms
    - New or worsening symptoms
- After Intracranial Hemorrhage:
  - Initial Imaging see **Head Trauma (HD-13.1)** in the Head Imaging Guidelines
  - Surveillance Imaging

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

    - Interval determined by neurosurgeon or neurologist or any provider in consultation with a neurologist or neurosurgeon.
- Carotid ultrasound screening in asymptomatic individuals due only to risk factors is **not** indicated.
- Repeat imaging of the cervical vessels (regardless of when the previous carotid imaging was performed) is medically necessary for new signs and symptoms consistent with carotid artery disease (e.g., TIA, amaurosis fugax, change in nature of a carotid bruit) using one of the following:
    - Duplex ultrasound (CPT® 93880 bilateral study or CPT® 93882 unilateral study)
    - MRA Neck with contrast or without and with contrast
    - CTA Neck

Evidence Discussion

Cerebrovascular and Carotid Disease- Initial Imaging

Indications for carotid artery imaging are suspicion for carotid stenosis, aneurysm, dissection or vasculitis. The signs and symptoms generally accepted for carotid imaging are listed in the guideline.

Standard first line imaging is the Duplex ultrasound (DU). This study obtains gray-scale pictures, as well as velocity and direction of blood flow in the vessels. The combination of B mode and Doppler techniques allows for detection of all of the above mentioned pathologies. DU has limitations in evaluation of the vertebral artery origins as well as extent of carotid dissection. Therefore, if there is concern for either vertebrobasilar insufficiency or carotid dissection, CT angiography (CTA) or MR angiography (MRA) is supported.

However, DU has become the first-line imaging modality for identifying patients with internal carotid artery stenosis. In part, this is because consensus ultrasound criteria have been developed to standardize carotid ultrasound examinations and categorize carotid artery stenosis severity. The rationale for use of DU is its low cost, availability, and high sensitivity and specificity. It avoids exposure to radiation and intravenous contrast agents as well.

CTA and MRA have more limited use for screening due to the risks associated with them. CTA risks include intravenous contrast and radiation exposure. Contrast complications include allergy and contrast induced nephropathy. MRA risk is related to use of gadolinium contrast, which confers the risk of nephrogenic systemic fibrosis in patients with renal insufficiency. MRA also is contraindicated in patients with metallic implants. Additionally, both CTA and MRA are not appropriate for screening purposes, due to their considerable costs.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

It is well established that for carotid stenosis 70-99% in an asymptomatic patient, or 50-99% stenosis in a symptomatic patient, there is a role for carotid intervention for stroke prevention. Once duplex identifies this degree of stenosis, CTA/MRA is medically necessary for pre-procedure planning. Additionally, CTA/MRA is medically necessary for patients undergoing evaluation for carotid artery stenting (CAS) as delineation of relevant anatomy is necessary for procedural success.

Surveillance Imaging with NO History of Carotid Surgery or Intervention (PVD-3.2)

PVD.CV.0003.2.A
v2.0.2026

- Surveillance imaging is medically necessary once a year for individuals with fibromuscular dysplasia of the extracranial internal carotid arteries.
- Reporting standards for carotid stenosis varies widely. The most commonly used criteria, however, is noted in the chart below published by the Society of Radiology in 2003

Primary parameters			Additional Parameters	
% Stenosis	ICA PSV (cm/sec)	Plaque estimate (%)	ICA/CCA PSV ratio	ICA/EDV (cm/sec)
Normal	< 125	None	< 2.0	< 40
< 50	< 125	< 50	< 2.0	< 40
50-69	125-230	≥ 50	2.0-4.0	40-100
≥ 70 but less than near occlusion	> 230	> 50	> 4.0	> 100
Near occlusion	High, low, or undetectable	Visible	Variable	Variable
Total occlusion	undetectable	Visible- no detectable lesion	Not applicable	Not applicable

CPT®	Description
70471	Computed tomographic angiography (CTA), head and neck, with contrast material(s), including noncontrast images, when performed, and image postprocessing

Proprietary Information of UnitedHealthcare.

CPT®	Description
70496	Computed tomographic angiography, head, with contrast material(s), including noncontrast images, if performed, and image postprocessing
70498	Computed tomographic angiography, neck, with contrast material(s), including noncontrast images, if performed, and image postprocessing
93880	Duplex Ultrasound, bilateral
93882	Duplex Ultrasound, unilateral
70544	Magnetic resonance angiography, head; without contrast material(s)
70545	Magnetic resonance angiography, head; with contrast material(s)
70546	Magnetic resonance angiography, head; without contrast material(s), followed by contrast material(s) and further sequences
70547	Magnetic resonance angiography, neck; without contrast material(s)
70548	Magnetic resonance angiography, neck; with contrast material(s)
70549	Magnetic resonance angiography, neck; without contrast material(s), followed by contrast material(s) and further sequences

- If normal study, no routine follow-up imaging is medically necessary
- If <50% internal carotid stenosis
  - Duplex ultrasound is medically necessary every **two** years
- Between 50% and 70% internal carotid stenosis
  - Duplex ultrasound is medically necessary annually.
  - A repeat duplex is medically necessary in three to six months until stability is reached when **one** of the following occurs:
    - Change in the character of the bruit
    - Duplex demonstrates rapid progression, including:
      - Doubling of peak systolic velocities in the internal carotid arteries
      - Increase of the ICA/CCA ratio
      - Heavy calcification in the internal carotid arteries
      - Thrombus in the internal carotid arteries
      - Ulcerated plaque in the internal carotid arteries
      - Echolucent plaque in the internal carotid arteries
  - A one-time CTA Neck (CPT® 70498) or MRA Neck is medically necessary to confirm degree of stenosis in individuals with ulcerated plaque or heavy calcification of the internal carotid artery seen on duplex.
- Internal carotid stenosis ≥70% or ICA/CCA ratio >4

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

    - Duplex ultrasound or MRA Neck with contrast or CTA Neck is medically necessary at the following intervals:
        - Every 6 months until one of the following occurs:
            - Intervention is performed
            - Decision is made to not intervene
- MRA Neck with contrast or CTA Neck is medically necessary if duplex Ultrasound shows ≥70% occlusion/stenosis of the internal carotid artery or the ICA/CCA ratio is >4.0, even with a lower percentage of stenosis.
    - If carotid stent is planned MRA Head or CTA Head can be added.

Evidence Discussion

Surveillance Imaging with NO History of Carotid Surgery or Intervention

DU is established as the primary diagnostic test for carotid surveillance imaging. Consensus statements have established the appropriate time intervals for repeat imaging. If however, there are new symptoms or physical findings, repeat duplex imaging is supported, regardless of time interval. If at any time there is >70% re-stenosis, CTA or MRA is indicated.

Surveillance Imaging WITH History of Carotid Surgery or Intervention (PVD-3.3)

PVD.CV.0003.3.A
v2.0.2026

- Duplex ultrasound (CPT® 93880 bilateral or CPT® 93882 unilateral) is medically necessary post-carotid surgery or intervention at the following intervals:
  - 1 month after procedure
  - Every 6 months for 2 years after procedure
  - Then annually
- If ≥70% residual internal carotid stenosis is seen on duplex at 1 month after procedure
  - Duplex ultrasound (CPT® 93880 bilateral or CPT® 93882 unilateral) or CTA Neck (CPT® 70498) or MRA Neck (CPT® 70548) is medically necessary at the following intervals:
    - Every 3-6 months for one year
    - Then annually or until decision is made to re-intervene.
- If ≥70% residual internal carotid stenosis is seen on duplex at any time post-procedure, then
  - CTA Neck (CPT® 70498) or MRA Neck (CPT® 70548) is medically necessary for further evaluation and at six-month intervals until decision is made to re-intervene.

Background and Supporting Information

- MRA Neck (CPT® 70548) or CTA Neck (CPT® 70498) may be medically necessary if ultrasound is technically difficult or confirmation of the degree of stenosis on ultrasound is needed because an interventional procedure is being considered

Evidence Discussion

Surveillance Imaging with WITH History of Carotid Surgery or Intervention

As described in PVD 3.1, Duplex Ultrasound is established as the primary diagnostic test for carotid surveillance imaging. Consensus statements have established the appropriate time intervals for repeat imaging. If however, there are new symptoms or physical findings, repeat duplex imaging is supported, regardless of time interval. If at any time there is >70% re-stenosis, CTA or MRA is indicated.

Aortic Disorders General Information (PVD-6.1)

PVD.AD.0006.1.A
v2.0.2026

Duplex ultrasound for visceral vascular studies	CPT®
Duplex scan of arterial inflow and venous outflow of abdominal, pelvic, scrotal contents and/or retroperitoneal organs; complete study.	93975
Duplex scan of arterial inflow and venous outflow of abdominal, pelvic, scrotal contents and/or retroperitoneal organs; limited study.	93976
Duplex scan of aorta, inferior vena cava, iliac vasculature, or bypass grafts; complete study.	93978
Duplex scan of aorta, inferior vena cava, iliac vasculature, or bypass grafts; unilateral or limited study.	93979
Ultrasound, abdominal aorta, real time, with image documentation, screening study for abdominal aortic aneurysm (AAA) for AAA screening	76706

- In clinical practice, CT, CTA, MRA are medically necessary to evaluate for stenosis of these vessels rather than ultrasound (Exception: Duplex ultrasound is medically necessary to rule out testicular or ovarian torsion or to evaluate an abdominal bruit or a pulsatile abdominal mass).
- Mesenteric Ischemia
  - See **Mesenteric/Colonic Ischemia (AB-6)** in the Abdomen Imaging Guidelines.

Thoracic Aortic Aneurysm (TAA) (PVD-6.2)

PVD.AI.0006.2.A
v2.0.2026

TAA Imaging Indications

Table of Thoracic Aorta Imaging Options

CPT®	Description
71250	Computed tomography, thorax, diagnostic; without contrast material
71260	Computed tomography, thorax, diagnostic; with contrast material(s)
71275	Computed tomographic angiography, chest (noncoronary), with contrast material(s), including noncontrast images, if performed, and image postprocessing
71555	Magnetic resonance angiography, chest (excluding myocardium), with or without contrast material(s)
93306	Transthoracic echocardiogram

Imaging of the thoracic aorta listed in the table above is considered medically necessary as follows:

- For suspected TAA, any requested imaging from the **Table of Thoracic Aorta Imaging Options** above is medically necessary for the following:
  - Abnormalities identified on chest x-ray (abnormality including widened mediastinum, suspicious calcification) or other imaging studies (fluoroscopy, MRI Spine, etc.) abnormality
- Imaging for known thoracic aortic aneurysm can be chosen from the Table of Thoracic Aorta Imaging Options above
- For screening of TAA, see **Screening for Vascular related genetic connective tissue Disorders (PVD-2.2)**
- For TAA associated with a dissection see **Aortic and Arterial Dissection and Other Aortic Conditions (PVD-6.7)**
- For known TAA accompanied with chest pain or back pain and suspicion of rupture, any requested imaging from the Table of Thoracic Aorta Imaging Options above.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- For thoracic endovascular aortic repair (TEVAR) of thoracic aorta disease either of the following is medically necessary:
  - CTA Chest, and/or Abdomen, and/or Pelvis (CPT® 71275, CPT® 74175, CPT® 72191, CPT® 74174)
  - MRA Chest, and/or Abdomen, and/or Pelvis (CPT® 71555, CPT® 74185, CPT® 72198)
- For follow-up of ascending aortic aneurysms, any requested imaging from the Table of Thoracic Aorta Imaging Options above is medically necessary for the following:
  - For individuals with ascending aortic aneurysms <4.0 cm in diameter
    - Repeat imaging annually
  - For individuals with ascending aortic aneurysms ≥4.0 cm
    - Repeat imaging 6 months.
  - TEE is medically necessary **only** when imaging with CT or MR is contraindicated
- For follow-up of descending aortic aneurysms, any requested imaging from the **Table of Thoracic Aorta Imaging Options** above for the following:
  - Medically treated/observation.
    - 3.5cm to 4.4 cm TAA can be followed annually.
    - ≥4.5 cm TAA can be followed every 6 months.
    - ≥3.0 cm TAA when there is concern for growth can have a one-time 3-month interval advanced imaging.
  - TEE is medically necessary **only** when imaging with CT or MR is contraindicated
- Screening in the presence of other aortic aneurysms.
  - In an individual with a known TAA, screening for AAA is medically necessary with an abdominal duplex. See **Abdominal Aortic Aneurysm (AAA) (PVD-6.3)**.
  - In an individual with a known AAA, screening for TAA is not supported by sufficient evidence and is not medically necessary.
- Screening in individuals with bicuspid aortic valve or familial TAA syndromes. See **Screening for TAA with bicuspid aortic valves (PVD-2.3)**. See **Screening for Vascular related genetic connective tissue Disorders (PVD-2.2)**

Evidence Discussion

Thoracic aortic aneurysms may enlarge over time. Once an aneurysm meets specific size criteria, its risk of rupture as well as the high mortality risk associated with rupture exceeds the risk of surgical intervention. Operative treatment is reasonable for asymptomatic individuals when the diameter of the arch exceeds 5.5 cm. Surveillance recommendations for ascending and descending thoracic aortic aneurysms have been addressed in several major studies.

The location of the thoracic aorta within the chest cavity limits the ability of noninvasive ultrasound to monitor aneurysm size. American College of Radiology recommendations

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

are for CT/MR imaging to monitor the thoracic aorta diameter to determine when surgical intervention is needed. Additionally, the American Heart Association also supports the use of transthoracic echocardiography to monitor the thoracic aortic diameter. In select patients with a difficult echocardiographic imaging window, transesophageal echocardiography is an alternative.

Thoracic aortic aneurysms may be isolated; however, they may extended below the diaphragm to include portions of the abdominal aorta. Abdominal aortic aneurysms should be followed according to their designated guidelines but may be included with thoracic imaging for certain planned interventions. Certain genetic and familial aneurysm syndromes may have a higher risk of TAA incidence and may warrant additional imaging for detection and surveillance. Additionally, most surgical approaches for thoracic aortic repair require CT/MR imaging for preoperative planning.

Abdominal Aortic Aneurysm (AAA) (PVD-6.3)

PVD.AD.0006.3.A
v2.0.2026

Duplex ultrasound for visceral vascular studies	CPT®
Duplex scan of arterial inflow and venous outflow of abdominal, pelvic, scrotal contents and/or retroperitoneal organs; complete study.	93975
Duplex scan of arterial inflow and venous outflow of abdominal, pelvic, scrotal contents and/or retroperitoneal organs; limited study.	93976
Duplex scan of aorta, inferior vena cava, iliac vasculature, or bypass grafts; complete study.	93978
Duplex scan of aorta, inferior vena cava, iliac vasculature, or bypass grafts; unilateral or limited study.	93979
Ultrasound, abdominal aorta, real time, with image documentation, screening study for abdominal aortic aneurysm (AAA) for AAA screening	76706

Screen for AAA

Ultrasound abdominal aorta with any of the studies from the table of Duplex ultrasound for visceral vascular studies is medically necessary to screen for AAA as follows:

- One-time screening recommendations for AAA (Ultrasound CPT® 76706)
  - Individuals 65 to 75 years of age with a history of tobacco use.
  - Individuals older than 75 years with a history of tobacco use and in otherwise good health who have not previously received a screening ultrasound examination.
  - All first-degree relatives of individuals who present with an AAA and are between 65 and 75, or in those older than 75 in good health.
- AAA screening is considered medically necessary with ultrasound (CPT® 76706, 93975, 93976, 93978, or 93979) when there is a documented thoracic aortic aneurysm

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- There is insufficient evidence to support the use of ultrasound or advanced imaging to screen for a thoracic aortic aneurysm in individuals with known abdominal aortic aneurysm.

Survey known AAA

Ultrasound abdominal aorta with any of the studies from the table of duplex ultrasound for visceral vascular studies is medically necessary to survey known AAA as follows:

- Surveillance of AAA with duplex ultrasound (CPT® 76706, 93975, 93976, 93978, 93979)
  - >2.5 cm but <3.0 cm: 5 years
  - 3.0 cm to 3.9 cm: 3 year intervals
  - 4.0 cm to 4.9 cm in a male: every 12 months OR 4.0-4.4cm in a female: every 12 months
  - ≥5.0 cm in a male OR ≥4.5cm in a female: every 6 months
  - >5.4 cm (or aortic diameter has increased in size by 0.5 cm in six months, or at least 1 cm in a year) may undergo more frequent monitoring and should be evaluated by a Vascular Specialist
- Additional imaging is considered medically necessary as follows:
  - CT Abdomen and Pelvis with contrast (CPT® 74177), CT Abdomen and Pelvis without contrast (CPT® 74176), or CTA Abdomen and Pelvis (CPT® 74174), or CTA Abdomen (CPT® 74175), or CTA Pelvis (CPT® 72191).
    - Suspected or known AAA with recent-onset abdominal or back pain, particularly in the presence of a pulsatile epigastric mass or significant risk factors for AAA
    - Pre-operative imaging for AAA repair
- A one-time CTA Chest (CPT® 71275) or CT Chest with contrast (CPT® 71260) is considered medically necessary prior to planned treatment of AAA.

Evaluate a pulsatile abdominal mass

Ultrasound abdominal aorta with any of the studies from the table of Duplex ultrasound for visceral vascular studies is medically necessary to evaluate a pulsatile abdominal mass:

- Additional Imaging with CT Abdomen and Pelvis with contrast (CPT® 74177), CT Abdomen and Pelvis without contrast (CPT® 74176), or CTA Abdomen and Pelvis (CPT® 74174), or CTA Abdomen (CPT® 74175), or CTA Pelvis (CPT® 72191) for either:
  - Suspected or known AAA with recent-onset abdominal or back pain, particularly in the presence of a pulsatile epigastric mass or significant risk factors for AAA

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Pre-operative imaging for AAA repair

Obese Individual (BMI ≥35)

- CT Abdomen and Pelvis with contrast (CPT® 74177) or without contrast (CPT® 74176) is medically necessary in an obese individual in place of US, or after an uninterpretable US, using the same timeline as a non-obese individual. Ultrasound abdominal aorta should ideally first be attempted to see if the image quality is adequate.

Evidence Discussion

Abdominal Aortic Aneurysm (AAA) Abdominal aortic aneurysmal disease is usually asymptomatic and discovered incidentally. Symptomatic aortic aneurysms are at high risk for rupture with a significant mortality risk and should be treated emergently with imaging and intervention as indicated. Screening for AAA has some benefit for high risk populations including some long-term tobacco users, individuals with known thoracic or other aneurysms and individuals with certain genetic or familial syndromes. Individuals found to have a pulsatile mass on abdominal exam may also warrant imaging for suspected aneurysmal disease.

For chronic aneurysms, several major studies have been performed with recommendations on surveillance frequency based on rupture risk. Once the rupture risk of an aneurysm meets or exceeds the risk of surgical repair, intervention is recommended. Most repair approaches use endovascular techniques that require preoperative imaging with CT/MR to determine specific anatomic data for appropriate device selection.

The anatomic location of abdominal aortic aneurysms allows ultrasound to be used as a primary imaging modality in most cases for surveillance. Ultrasound uses no radiation or contrast, can be performed in an outpatient setting and is cost-effective. CT/MR imaging is usually reserved for intervention planning or for cases where ultrasound has been found to have technical limitations related to body habitus or other structural issues.

For surgical planning, CT/MR imaging is frequently used to determine anatomic parameters. As many abdominal procedures may require instrument placement within the thoracic aorta, preoperative chest imaging is often a necessary component to surgical planning.[2]

Time between surveillance US in individuals with non-aneurysmal, but dilated aortic diameters, has been shortened, because there is increasing evidence that a significant portion of these individuals will progress to a AAA diameter that may require repair. In addition, because female patients were found to have a significantly higher risk of

rupture, more frequent surveillance imaging is justified at AAA diameter of 4 cm and larger.[3]

National guidelines support repair of asymptomatic abdominal aortic aneurysm of ≥5.5cm in males and ≥5.0cm in females. Evidence shows sex related variations in aortic size contributing to a higher risk for rupture at a given aortic diameter in females.[4]

CPT®	Imaging for Aortic conditions
74160	Computed tomography, abdomen; with contrast material(s)
74170	Computed tomography, abdomen; without contrast material, followed by contrast material(s) and further sections
74178	Computed tomography, abdomen and pelvis; without contrast material in one or both body regions, followed by contrast material(s) and further sections in one or both body regions
72193	Computed tomography, pelvis; with contrast material(s)
72194	Computed tomography, pelvis; without contrast material, followed by contrast material(s) and further sections
74174	Computed tomographic angiography, abdomen and pelvis, with contrast material(s), including noncontrast images, if performed, and image postprocessing
74175	Computed tomographic angiography, abdomen, with contrast material(s), including noncontrast images, if performed, and image postprocessing
74185	Magnetic resonance angiography, abdomen, with or without contrast material(s)
72191	Computed tomographic angiography, pelvis, with contrast material(s), including noncontrast images, if performed, and image postprocessing
72198	Magnetic resonance angiography, pelvis, with or without contrast material(s)

CTA or MRA of the entire aorta (including arch branches) and extending through the femoral arteries is medically necessary for suspected acute aortic dissection with any of the following study combinations:

- CT Chest **and/or one of the following:**
  - CT Abdomen with or without and with contrast
  - CT Pelvis with or without and with contrast
  - CT Abdomen and Pelvis with or without and with contrast
- CTA Chest and/or **one** of the following:
  - CTA Abdomen
  - CTA Pelvis
  - CTA Abdomen and Pelvis

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

- MRA Chest and/or Abdomen and/or Pelvis

Surveillance

Any aortic dissection, regardless of treatment modality (medical or surgical), imaging of the chest, abdomen and pelvis (according to the Imaging for Aortic Conditions table above) is medically necessary at the following intervals:

- 1 month
- 6 months
- 12 months
- If stable, annually

In individuals with Marfan syndrome/Loeys-Dietz/Ehlers-Danlos and an aortic dissection, post-dissection imaging of the chest, abdomen and pelvis (according to the Imaging for Aortic Conditions table above) is medically necessary as follows:

- 1 month
- 3 months
- 6 months
- 12 months
- yearly thereafter

If the dissection extends into the head or neck, any of the following imaging is also medically necessary at the same intervals:

- MRA Head and/or MRA Neck or
- Carotid duplex CPT or
- CTA Neck or
- CTA Head or
- CTA Head and Neck

Imaging of asymptomatic and/or incidentally found arterial dissections that do not affect the aorta (such as, iliac arteries, visceral arteries, extracranial arteries) is medically necessary according to the general schedule as follows:

- Within one month of discovery
- Six months
- 12 months
- No further imaging after 12 months if noted to be stable

Imaging of asymptomatic penetrating aortic ulcers treated medically is medically necessary according to the following time intervals as follows:

- One month after diagnosis
- If stable, every 6 months for 2 years

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Then at appropriate intervals thereafter (depending on patient age and PAU characteristics) as determined by the provider managing the condition

Evidence Discussion

Aortic and arterial dissection is usually a result of vessel wall damage due to uncontrolled hypertension or physical trauma. Some connective tissue and genetic disorders also carry a higher risk for vessel dissection. Emergent cases usually present with symptoms of impending vessel rupture, organ malperfusion or hemodynamic instability. For these cases, advanced imaging is required for surgical planning. Additional imaging of anatomic regions with suspected involvement are considered necessary in these cases. Acute dissection cases without these features may be observed with medical management until stable.

A chronic arterial dissection will often degenerate into an aneurysm over time. The risk is related to the dissected area of aorta, as well as non-dissected native aortic segments because of underlying medial degeneration. Multiple major studies have been conducted to recommend criteria for intervention based on size and anatomic considerations. Individuals with certain genetic syndromes including Marfan, Loeys-Dietz and Ehlers-Danlos Type IV may be at risk for accelerated vessel degeneration and should undergo more frequent surveillance.

Due to the complex anatomy associated with arterial dissection, CT/MR imaging is recommended over duplex imaging for thoracic, abdominal and visceral artery dissections. Duplex imaging may still be useful for carotid monitoring depending on the extent of vessel involvement.

Asymptomatic arterial dissections not associated with the aorta should undergo regular surveillance for the first year after detection. No further imaging has found to be of benefit if findings remain stable.

Penetrating aortic ulcers are frequently found in the setting of severe aortic atherosclerosis and may carry a significant rupture risk. Frequent surveillance for the first year after detection is medically necessary to determine if intervention is necessary. If the penetrating aortic ulcer remains stable after twelve months, the frequency of imaging may be reduced to annually until intervention is indicated.

Classic symptoms of sharp, severe acute onset of retrosternal or interscapular chest pain is seen in 96% and is best adapted to the emergent setting. Chest x-ray is imprecise; any suspicion should be considered since up to 10% of individuals with aortic dissection present without classic symptoms.

Post Aortic Endovascular/Open Surgery Surveillance Studies (PVD-6.8)

PVD.AD.0006.8.A
v2.0.2026

Open Procedures

- Aortic root/ascending aortic procedures for aneurysm/dissection (ex: aortic root repair, arch/hemi-arch repair, Elephant trunk repair). One of the following post-operative studies [Echocardiography or CT Chest with contrast (CPT® 71260) or CT Chest without contrast (CPT® 71250) or CTA Chest (CPT® 71275)], is medically necessary as follows:
  - Within 1 year post-operative
  - Then every 5 years
- Open descending thoracic aortic aneurysm repair- **One** of the following post-operative studies [CT Chest with contrast (CPT® 71260) **or** CT Chest without contrast (CPT® 71250) **or** CTA Chest (CPT® 71275)], is medically necessary as follows:
  - Within 1 year post-operative
  - Then every 5 years
- Open Aortic Abdominal Aneurysm Repair - contrast and non-contrast enhanced CT of the entire aorta (CPT® 74176, CPT® 74177, CPT® 74174) is medically necessary as follows:
  - Within 1 year post-operative
  - Then every 5-years
  - As requested to assess for suspected infection of the graft (see **Vascular Graft Infection (PVD-21)** for additional imaging in vascular graft infection).

Proprietary Information of UnitedHealthcare.

Endovascular procedures

Post-operative surveillance after TEVAR for any indication (PVD-6.8.1)

Imaging for post-operative TEVAR	CPT®
CT Chest, and/or Abdomen, and/or Pelvis	71260 74177 74160 72193
CTA Chest, and/or Abdomen, and/or Pelvis	71275 74175 72191 74174
MRA Chest, and/or Abdomen, and/or Pelvis	71555 74185 72198

Note:

Abdomen and Pelvis imaging is medically necessary only if TEVAR performed for a dissection that extends into the abdomen or pelvis

- **Any** of the studies listed in the table above are medically necessary for post-operative surveillance imaging after TEVAR as follows:
  - One month
  - Twelve months
  - Then annually for life
- If an endoleak is identified at the 1-month study, more frequent imaging is considered medically necessary as requested.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Post-operative surveillance after abdominal EVAR (endovascular aneurysm repair) (PVD-6.8.2)

Imaging for post-operative abdominal EVAR	CPT®
CT Abdomen and/or Pelvis with contrast	74160 72193 74177
CT Abdomen and/or Pelvis without and with contrast	74170 72194 74178
CTA Abdomen and/or Pelvis	74175 72191 74174
MRA Abdomen and/or Pelvis	74185 72198

Post-operative surveillance after abdominal EVAR is medically necessary as follows:

- CT (any contrast level) or CTA of the entire aorta at 5-year intervals (CPT® 74176)
- CT as per above coding as requested and color duplex ultrasound (CPT® 93975, CPT® 93976, CPT® 93978, or CPT® 93979) one month after EVAR
- If no endoleak, or sac enlargement, repeat either preferred CT or duplex ultrasound (but not both) at 12 months
- If a type II endoleak is observed 1 month after EVAR, may approve **both** at 6 months:
  - Any of the above CT with contrast
  - Color duplex US
- If no endoleak or AAA sac enlargement is detected at 1 year after EVAR annual surveillance with:
  - Color duplex US
  - If DGUS is not available, any of the above CT can be performed
- If a type II endoleak is associated with an aneurysm sac that is shrinking or stable in size:
  - Continue surveillance with color duplex US every 6 months for 2 years

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

  - Annually thereafter.
- If US detects a new endoleak, graft migration, or aneurysm sac growth > 5mm:
  - Any of the above CT scan as requested

Post-endoleak intervention surveillance imaging

Surveillance imaging after EVAR, or any subsequent endoleak intervention, is based on the most recent intervention.

For any subsequent interventions for endoleak repair, imaging is medically necessary at 1 month with CT and then follow protocol as above.

Surveillance following Complex EVAR (i.e., a branched/fenestrated graft)

CT as per above coding as requested and/or color duplex ultrasound (CPT® 93975, CPT® 93976, CPT® 93978, or CPT® 93979) is medically necessary at 1-month post-operative, 6 months post-operative, 12 months post-operative, and annually thereafter.

A 3 month follow-up study is considered medically necessary if endoleak of aneurysm enlargement is identified at 1-month post-operative.

Endovascular (Stent) Iliac Repair (PVD-6.8.3)

Imaging for endovascular iliac repair (stent)	CPT®
CT Pelvis	72193 72194
CTA Pelvis	72191
MRA Pelvis	72198

- One of the above studies is medically necessary for endovascular iliac repair (stent)
- If performed in conjunction with EVAR, surveillance will follow the same schedule as EVAR.
- For isolated iliac artery aneurysm repair, surveillance is medically necessary with an arterial duplex (CPT® 93975, CPT® 93976, CPT® 93978, or CPT® 93979) or CT or MR as above if duplex unavailable:
  - Post-cooperatively within the first month
  - 6 months after endovascular treatment
  - Annually

Evidence Discussion

Post Aortic Endovascular/Open Surgery Surveillance Studies

Surgical approaches to aortic repair have evolved over the past several decades. Open repair is still common for treatment of ascending aortic pathology as well as some thoracic/abdominal aortic disease with complex anatomy. In recent years, however, advances in endovascular technology have made this modality preferred for descending thoracic, abdominal and iliac artery repairs.

Multiple studies have been performed with several recommendations for aortic graft surveillance depending on anatomic location and repair type. Open repair surveillance tends to use longer frequency intervals due to the durability of the repair approach. While less invasive, endovascular repairs require more frequent monitoring as the graft components have a higher risk of technical complication with a need for repeat intervention.

When an endovascular graft system becomes displaced or does not adhere properly to the native vessel wall, an endoleak may develop. An endoleak increases the risk of rupture within a previously repaired aneurysm sac and may require repeat intervention. Some endoleak types may be monitored with regular surveillance if the aneurysm sac diameter remains stable. However, if the aneurysm sac increases in size or if a high risk endoleak type is detected, repeat intervention with preoperative imaging is medically necessary to prevent rupture. Post-endoleak repairs also require regular surveillance as these may also be at risk for technical failure over time.

Thoracic aortic surveillance imaging is usually performed with CT/MR due to the anatomic limitations of duplex in this region. Abdominal aortic surveillance after endovascular repair is initially performed with CT/MR to ensure proper alignment of all graft components. Once this has been established, surveillance with duplex ultrasound is medically necessary unless technical limitations are noted. If an endoleak is detected or if additional pathology such as graft infection is suspected, CT/MR imaging would be appropriate to provide additional anatomic detail. Similarly, if there is concern for repeat intervention, preoperative imaging with CT/MR is indicated.

Complex endovascular aneurysm repair refers to techniques that address branch vessels with branches, stents, or fenestration. These techniques allow for minimally invasive repair of complicated anatomy but need for secondary intervention is relatively high. While duplex ultrasound may be useful for surveillance in these cases, CT scan allows for more detailed imaging and may be useful in some cases.

Post-procedure Surveillance Studies (PVD-7.3)

PVD.AI.0007.3.A
v2.0.2026

- Scheduled Interval
  - ABI (CPT® 93922) following any revascularization procedure
    - ABI (CPT® 93922) or Duplex ultrasound (CPT® 93926 unilateral study) at each routine follow-up is medically necessary generally after a history/physical has been performed
    - Further imaging studies such as CTA or MRA are medically necessary for worsening symptoms, an abnormal duplex or a significant reduction (>0.15) in the ABI

Indication	Imaging
Suprainguinal Revascularization, both open and endovascular therapy, including Aortobifem/iliofem/fem-fem bypass/iliac angioplasty/stent	• Clinical examination and ABI (CPT® 93922) with arterial duplex (CPT® 93925 or CPT® 93926) is medically necessary at: ◦ Within 1 month ◦ 6 months ◦ 12 months ◦ Then annually
Infrainguinal Open Revascularization (Femoral-popliteal, femoral-tibial, femoral-distal bypass)	
• With vein or autologous conduit	• Clinical exam and ABI (CPT® 93922) with arterial duplex (CPT® 93925 or CPT® 93926) is medically necessary at: ◦ Post-operatively ◦ 3 months ◦ 6 months ◦ 12 months ◦ Then annually

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Indication	Imaging
• With Prosthetic conduit (PTFE/Dacron)	• Clinical exam and ABI (CPT® 93922) with arterial duplex (CPT® 93925 or CPT® 93926) is medically necessary at: ◦ Post-operatively ◦ 6 months ◦ 12 months ◦ Then annually
Infrainguinal Endovascular Revascularization Femoropopliteal angioplasty/stent	• Clinical exam and ABI (CPT® 93922) with arterial duplex (CPT® 93925 or CPT® 93926) is medically necessary at: ◦ Within 1 month ◦ 3 month ◦ Every 6 months for two years ◦ Then annually

After suprainguinal intervention (PVD-7.3.1)

- One of the following studies: Arterial duplex, CTA Abdomen and Pelvis, CT Abdomen and Pelvis with contrast, CTA Aorta with lower extremity runoff, MRI Abdomen and Pelvis, MRA Abdomen and Pelvis, or MRA Aorta with lower extremity runoff is medically necessary for any **one** of the following:
  - Worsening signs or symptoms
  - Reduction of ABI >0.15
  - Peak systolic velocities or PSV ratio suggestive of high grade stenosis or in-stent re-stenosis

After infrainguinal intervention (PVD-7.3.2)

- CTA Lower Extremity (CPT® 73706) or MRA Lower Extremity (CPT® 73725) or CTA aorta with lower extremity runoff CPT® 75635) is medically necessary for any **one** of the following:
  - Worsening signs or symptoms
  - Reduction of ABI >0.15
  - Duplex suggestive of threatened graft
- If intervention was performed for a non-healing wound and wound has gone on to heal, additional imaging is **not** medically necessary for surveillance.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Repeat arterial duplex imaging can be obtained for worsening clinical signs and symptoms such as the presence of a new wound or rest pain

Evidence Discussion

Post-procedure Surveillance Studies

Once an intervention (open or endovascular) has been performed, surveillance imaging is supported. The rationale for this is to maintain patency of the treated lesions to avoid further symptoms and/or amputation. Surveillance imaging with ABI and duplex is supported at various intervals depending on the type of intervention, stent vs. bypass, and by bypass material.

Large Vessel Vasculitis (PVD-6.9)

PVD.AD.0006.9.A
v2.0.2026

Inflammatory Aortitis (PVD-6.9.1)

Imaging for Inflammatory Aortitis	CPT®
CTA Chest	71275
MRA Chest	71555
CTA Pelvis	72191
MRA Pelvis	72198
CTA Abdomen and Pelvis	74174
CTA Abdomen	74175
MRA Abdomen	74185

Initial imaging

- Initial imaging with CTA or MRA of the affected body region is considered medically necessary when clinical evaluation leads to the suspicion of inflammatory aortitis.

Repeat imaging

- Follow-up imaging with CTA or MRA of the affected body region is considered medically necessary for:
  - Change in signs/symptoms
  - Known aneurysm monitoring
    - See **Cerebral Aneurysm and AVM (HD-12)** in the Head Imaging Guidelines
    - See **TAA Imaging Indications**
    - See **Abdominal Aortic Aneurysm (AAA) (PVD-6.3)**

Giant Cell Arteritis (GCA) (PVD-6.9.2)

CPT®	Imaging for Giant Cell Arteritis
70544	Magnetic resonance angiography, head; without contrast material(s)
70545	Magnetic resonance angiography, head; with contrast material(s)
70546	Magnetic resonance angiography, head; without contrast material(s), followed by contrast material(s) and further sequences
70547	Magnetic resonance angiography, neck; without contrast material(s)
70548	Magnetic resonance angiography, neck; with contrast material(s)
70549	Magnetic resonance angiography, neck; without contrast material(s), followed by contrast material(s) and further sequences
71275	Computed tomographic angiography, chest (noncoronary), with contrast material(s), including noncontrast images, if performed, and image postprocessing
71555	Magnetic resonance angiography, chest (excluding myocardium), with or without contrast material(s)
74174	Computed tomographic angiography, abdomen and pelvis, with contrast material(s), including noncontrast images, if performed, and image postprocessing
74175	Computed tomographic angiography, abdomen, with contrast material(s), including noncontrast images, if performed, and image postprocessing
72191	Computed tomographic angiography, pelvis, with contrast material(s), including noncontrast images, if performed, and image postprocessing
74185	Magnetic resonance angiography, abdomen, with or without contrast material(s)
72198	Magnetic resonance angiography, pelvis, with or without contrast material(s)
73725	Magnetic resonance angiography, lower extremity, with or without contrast material(s)
78815	Positron emission tomography (PET) with concurrently acquired computed tomography (CT) for attenuation correction and anatomical localization imaging; skull base to mid-thigh

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

CPT®	Imaging for Giant Cell Arteritis
78816	Positron emission tomography (PET) with concurrently acquired computed tomography (CT) for attenuation correction and anatomical localization imaging; whole body

Initial imaging

Cranial GCA is the more common type with temporal artery involvement. For predominantly Cranial GCA the following studies are considered medically necessary for initial imaging:

- US (CPT® 93880 or CPT® 93882) of the temporal (and or axillary) arteries is the preferred modality where available.
- MRA Head and/or MRA Neck when **either** of the following apply:
  - Vascular trained ultrasonography is not available
  - US is negative or equivocal with a clinical suspicion of GCA
- MRA of the Abdomen and/or Lower extremities when involvement suspected clinically
- PET/CT Whole Body is considered medically necessary when MRA or US are equivocal and one of the following conditions exists:
  - temporal artery biopsy is negative and GCA is still suspected
  - where the result would change clinical management
- US of the neck vessels (CPT® 93880 or CPT® 93882) and MRA Chest

Note:

For suspected cerebral vasculitis in individuals with neurological symptoms, see **Cerebral Vasculitis (HD-22)** in the Head Imaging Guidelines

Extra-cranial GCA: less commonly encountered. None of the “classic” clinical signs or symptoms of cranial GCA are present initially but may develop later.

- Extra-cranial GCA is characterized by at least two or more of the following:
  - Jaw and/or upper extremity claudication
  - Fever/weight loss or fever of unknown origin (FUO) symptoms
  - New murmurs
  - Pulse asymmetry
  - Abdominal pain
  - Pulsatile mass
  - High inflammatory markers such as CRP or ESR > 50 mm/h
- Medically necessary imaging for aortic root, arch or abdomen involvement:
  - MRA Chest, MRA Neck , MRA Abdomen , CTA Chest , CTA Neck or CTA Abdomen

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- PET/CT Skull base to mid thigh if MRA or CTA are non-diagnostic and there is still suspicion for aortic root, arch or abdomen involvement

Repeat imaging

- Follow-up imaging is medically necessary for **any** of the following:
  - One-time documentation of remission or disease control
  - Change in signs/symptoms suggesting progression of disease
  - Although individuals with GCA can develop aortic aneurysms over time screening in the absence of signs or symptoms is not medically necessary
  - In individuals with known thoracic or abdominal aortic aneurysm:
    - See **TAA Imaging Indications** for thoracic aneurysm surveillance
    - See **Abdominal Aortic Aneurysm (AAA) (PVD-6.3)** for abdominal aneurysm surveillance.
- Follow-up imaging is not considered medically necessary for individuals in clinical and biochemical remission or without aneurysm/complication.

Takayasu's Arteritis (PVD-6.9.3)

CPT®	Imaging for Takayasu's Arteritis
71275	Computed tomographic angiography, chest (noncoronary), with contrast material(s), including noncontrast images, if performed, and image postprocessing
72191	Computed tomographic angiography, pelvis, with contrast material(s), including noncontrast images, if performed, and image postprocessing
74174	Computed tomographic angiography, abdomen and pelvis, with contrast material(s), including noncontrast images, if performed, and image postprocessing
74175	Computed tomographic angiography, abdomen, with contrast material(s), including noncontrast images, if performed, and image postprocessing
71555	Magnetic resonance angiography, chest (excluding myocardium), with or without contrast material(s)
72198	Magnetic resonance angiography, pelvis, with or without contrast material(s)
74185	Magnetic resonance angiography, abdomen, with or without contrast material(s)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

CPT®	Imaging for Takayasu's Arteritis
78815	Positron emission tomography (PET) with concurrently acquired computed tomography (CT) for attenuation correction and anatomical localization imaging; skull base to mid-thigh

Initial imaging

- Initial imaging is medically necessary for signs and symptoms suggestive of disease such as absent radial pulse, difficulty obtaining BP in one arm, or unexplained hypertension.
- Initial staging PET-CT is considered medically necessary in place of MRA or CTA of multiple areas when diffuse large vessel involvement, or occult vessel involvement, is suspected.
- Any of the following modalities are medically necessary for evaluation of Takayasu's arteritis:
  - MRA of the affected body area(s) (contrast as requested)
  - CTA of the affected body area(s) (contrast as requested)
  - Ultrasound with Doppler of the affected body area(s)

Repeat imaging

Repeat imaging with any CTA or MRA in the above table is medically necessary at the following intervals:

- Every 3 months to monitor treatment response during active treatment with systemic therapy.
- Annually for surveillance of known involved body areas to detect progressive vascular damage that may require intervention

Evidence Discussion

Large Vessel Vasculitis

Large vessel vasculitis is generally sub-grouped into three areas

- Aortitis (Inflammatory Aortitis)
- Giant Cell Vasculitis
- Takayasu's Arteritis

Initial diagnosis of large vessel vasculitis (Inflammatory aortitis, Giant cell, and Takayasu's arteritis) should be made through history, physical exam and laboratory values including inflammatory markers. In cases of suspected large vessel disease, ultrasound, CT/ and MR imaging of the neck/chest/abdomen/pelvis are indicated.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

PET imaging should be reserved for cases where CT/MR are non-diagnostic and the likelihood of disease based on other factors is high.

PET imaging has recently been incorporated into the American College of Rheumatology GL for the Diagnosis of GCA, for research purposes and to exclude alternate diagnosis.[5] PET can be utilized in the rare instances MRA or US are equivocal, temporal artery biopsy is negative and GCA is still suspected, or where the result would change clinical management.[6,7]

Aortic arch involvement is common (see below); US of the neck vessels and MRA of the chest may also be considered in initial screening. Abdominal involvement is less common in GCA, but common in Takayasu's arteritis (see below). MRA of the abdomen and/or LE's, may also be considered in initial screening when involvement suspected clinically.[1,3]

Aortitis

Aortitis may be congenital (Marfan, Hypermobility Syndromes, others) or acquired, including traumatic, atherosclerotic (dissecting aneurysm, other), infectious (syphilis, tuberculosis, other), neoplastic or inflammatory (Ankylosing Spondylitis, Giant Cell Arteritis, Cogan's, Relapsing Polychondritis, Behcet's Syndrome, Polyarteritis Nodosa, Granulomatous Polyangiitis, Lupoid, idiopathic, other).

Giant Cell Arteritis

Historically, GCA had been be subdivided into two basic types; Cranial Predominant and Extra-cranial Currently, both GCA type vasculitis and Takayasu's arteritis have similar management requirements as variants of Large vessel vasculitis (LVV).

Initial diagnosis of large vessel vasculitis (Inflammatory aortitis, Giant cell, and Takayasu's arteritis) should be made through history, physical exam and laboratory values including inflammatory markers. In cases of suspected large vessel disease, ultrasound, CT/ and MR imaging of the neck/chest/abdomen/pelvis are may be indicated. PET imaging should be reserved for cases where CT/MR are non-diagnostic and the likelihood of disease based on other factors is high. Follow-up imaging is medically necessary for individuals with known aneurysmal disease or who remain symptomatic on active therapy. PET imaging has recently been

incorporated into the American College of Rheumatology GL for the Diagnosis of GCA, for research purposes and to exclude alternate diagnosis.[1]

Takayasu's Arteritis

Instead of multiple MRA's, an initial staging PET-CT can be approved where diffuse large vessel involvement, or occult vessel involvement, is suspected in an LVV. Ordering both studies initially is discouraged. Follow-up MRA is preferred as PET-CT in some patients may never normalize. For Takayasu's arteritis, annual surveillance in the absence of symptoms is recommended due to the high risk of progressive vascular damage.

Medium Vessel Vasculitis (PVD-6.10)

PVD.AD.0006.10.A
v2.0.2026

- There are two main types of medium-size vessel vasculitis:
  - Kawasaki disease
  - Polyarteritis Nodosa

Kawasaki disease

- Imaging guidelines below for Kawasaki Disease can also be accessed in **Kawasaki Disease (PEDCD-6)** in the Pediatric Cardiac imaging guideline

Long term routine surveillance in asymptomatic imaging for Kawasaki disease

AHA risk level	Largest Aneurysm At Any Point	Largest Current Aneurysm	Routine Echo	Routine Stress Imaging	Routine Coronary Imaging
All			All risk levels 4-6 weeks after acute illness		
1	Normal	Normal	One echo 2-12 months after acute illness	none	none
2	Dilation	Dilation	6 months One year If dilation remains echo every 2-5 years until resolves	None	None
		Normal	After acute illness: 2-12 months One echocardiogram at one year No echocardiogram after one year

AHA risk level	Largest Aneurysm At Any Point	Largest Current Aneurysm	Routine Echo	Routine Stress Imaging	Routine Coronary Imaging
5.4	Large	Normal Or Dilation	1-2 years	2-5 years	none

Polyarteritis Nodosa

Initial imaging

Any ONE of the following modalities is medically necessary for documented clinical suspicion of Polyarteritis Nodosa:

- MRA of the affected body area(s) (contrast as requested)
- CTA of the affected body area(s) (contrast as requested)
- Ultrasound (US) with Doppler of the affected body area(s)

Repeat imaging

Imaging with MRA, CTA, or US with Doppler of the affected body area(s) is medically necessary for established Polyarteritis Nodosa as follows:

- Every 3 months during active treatment with systemic therapy to evaluate treatment response
- Annually for surveillance of known involved body areas to detect progressive vascular damage that may require intervention

Background and Supporting Information

- Based on AHA recommendations, the following classifications are used in risk stratification of coronary artery abnormalities[8]:
  - Z-score classification accounts for the effects of body size and age through use of baseline coronary dimensions adjusted for body surface area. The z-score value represents the number of standard deviation above the mean. (e.g., z=0 pt. has coronary artery dimension value equal to mean, z=2 person has value 2 standard deviation above the mean, based on age, gender, BSA).
  - Coronary Artery Abnormalities Risk Classification based on z-score:
    - 1 - No involvement at any time point (z-score always <2)
    - 2 - Dilation only (z-score 2 to <2.5)
    - 3 - Small aneurysm (z-score ≥2.5 to <5)
      - 3.1 - Current or persistent

[8] Mccrindle BW, Rowley AH, Newburger JW, et al. Diagnosis, Treatment, and Long-Term Management of Kawasaki Disease: A Scientific Statement for Health Professionals from the American Heart Association. Circulation. 2017;135(17). doi:10.1161/cir.0000000000000484.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

    - 3.2 - Decreased to dilation only or normal luminal dimension
  - 4 - Medium aneurysm (z-score ≥5 to <10, and absolute dimension <8 mm)
    - 4.1 - Current or persistent
    - 4.2 - Decreased to small aneurysm
    - 4.3 - Decreased to dilation only or normal luminal dimension
  - 5 - Large and giant aneurysm (z-score ≥10, or absolute dimension ≥8 mm)
    - 5.1 - Current or persistent
    - 5.2 - Decreased to medium aneurysm
    - 5.3 - Decreased to small aneurysm
    - 5.4 - Decreased to dilation only or normal luminal dimension
- Additional clinical features that may increase the long-term risk of myocardial ischemia:
  - Greater length and distal location of aneurysms that increase the risk of flow stasis
  - Greater total number of aneurysms
  - Greater number of branches affected
  - Presence of luminal irregularities
  - Abnormal characterization of the vessel walls (calcification, luminal myofibroblastic proliferation)
  - Presence of functional abnormalities (impaired vasodilation, impaired flow reserve)
  - Absence or poor quality of collateral vessels
  - Previous revascularization performed
  - Previous coronary artery thrombosis
  - Previous myocardial infarction
  - Presence of ventricular dysfunction

Evidence Discussion

Medium Vessel Vasculitis

Medium vessel vasculitis includes multiple inflammatory processes that affect the major arteries the cerebrovascular, thoracic and abdominal regions. Cardiac involvement is also common. Pediatric populations are most often affected. Aneurysmal degeneration risk is high and does require regular surveillance. The two most common types include:

- Kawasaki disease
- Polyarteritis nodosa

Initial diagnosis should be made through history, physical exam and laboratory values including inflammatory markers. Aneurysmal degeneration of vessels may be seen in

Click Here to Return to the Main TOC

multiple anatomic regions. For individuals with suspected disease, ultrasound, CT and MR imaging of the neck/chest/abdomen/pelvis is indicated.

Annual surveillance in the absence of symptoms is still recommended due to the high risk of progressive vascular damage.

Small Vessel Vasculitis (PVD-6.11)

PVD.AD.0006.11.A
v2.0.2026

- Advanced imaging is not sensitive enough to detect changes in small vessels, and is not medically necessary for primary assessment of any small vessel vasculitis.
- End-organ damage can occur with several of the small vessel vasculitides and are addressed in this guideline:
  - Henoch-Schönlein Purpura (HSP)
  - Granulomatosis with polyangiitis (GPA, formerly known as Wegener's granulomatosis)
  - Eosinophilic granulomatosis with polyangiitis (EGPA, formerly known as ChurgStrauss Syndrome)
  - Immune complex associated small-vessel vasculitis [immunoglobulin A–associated vasculitis (IgAV)]

IgA Vasculitis Henoch-Schönlein Purpura (HSP)

Initial imaging

Ultrasound (US) Abdomen (CPT® 76700) is medically necessary to evaluate possible gastrointestinal complications of known or suspected HSP including **any** of the following:

- Bowel wall edema and hemorrhage
- Intussusception

CT Abdomen with contrast (CPT® 74160) is medically necessary if additional information is needed after ultrasound for management

Repeat imaging

US Abdomen (CPT® 76700) is medically necessary for known HSP to evaluate new or worsening gastrointestinal symptoms

Background and Supporting Information

Henoch-Schönlein Purpura (HSP) is the most common vasculitis of childhood, mainly involving small blood vessels.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Granulomatosis with Polyangiitis (GPA) Formerly Wegener's Granulomatosis

Initial Imaging

Initial imaging as a baseline prior to starting immunosuppressive therapy is medically necessary in all individuals who are newly diagnosed or suspected of having antineutrophil cytoplasmic autoantibody (ANCA)-associated vasculitides (AAV) with either or both of the following to evaluate the extent of the disease:

- CT Sinuses (CPT® 70486) and/or
- CT Chest without contrast (CPT® 71250) or with contrast (CPT® 71260)

Note:

Preferred CT imaging in individuals with AAV should be performed without an iodinated contrast agent administered.

Repeat Imaging

CT Sinuses (CPT® 70486) and/or CT Chest without contrast (CPT® 71250) or CT Chest with contrast (CPT® 71260) are medically necessary for **any** of the following:

- New or worsening clinical symptoms affecting the body area requested
- Assess response to medical therapy when a change in treatment regimen is being considered
- Annually-to evaluate the extent of disease

Eosinophilic Granulomatosis with Polyangiitis (EGPA) Formerly Churg-Strauss Syndrome

Initial Imaging

- CT Chest without contrast (CPT® 71250) or CT Chest with contrast (CPT® 71260) is medically necessary in the initial evaluation of Eosinophilic granulomatosis with polyangiitis (EGPA) formerly known as Churg-Strauss Syndrome.

Repeat Imaging

- CT Chest without contrast (CPT® 71250) or CT Chest with contrast (CPT® 71260) is medically necessary for any of the following:
  - New or worsening clinical symptoms affecting the body area requested

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Assess response to medical therapy when a change in treatment regimen is being considered
- Annually-to evaluate the extent of disease

Immune Complex Associated Small-vessel Vasculitis

Initial Imaging

- Doppler ultrasound (US) of the affected body part (most commonly abdomen) is medically necessary in the initial evaluation of immune complex associated small-vessel vasculitis

Repeat Imaging

- Doppler ultrasound (US) of the affected body part (most commonly abdomen) is medically necessary in the following circumstances
  - New or worsening clinical symptoms affecting the body area requested
  - To assess response to medical therapy when a change in treatment is being considered
  - Annually-to evaluate the extent of disease

Evidence Discussion

Small Vessel Vasculitis

Advanced imaging is not routinely needed with diagnosis of Small vessel vasculitis. In suspected cases, clinical assessment of end-organ damage is usually indicated in both the adult and pediatric population

Initial diagnostic workup should include history, physical exam, and laboratory data including inflammatory markers. End-organ damage may involve multiple organ systems based on the type of vasculitis. For individuals with suspected disease, ultrasound, CT and MR imaging of the affected anatomic regions may be indicated. Annual surveillance in the absence of symptoms is still recommended due to the high risk of progressive vascular damage.

Visceral Artery Aneurysm (PVD-6.5)

PVD.AD.0006.5.A
v2.0.2026

Treatment is generally indicated for visceral aneurysms ≥2cm. Imaging of visceral artery aneurysms for initial evaluation or for treatment planning is medically necessary as follows:

- Initial imaging of calcifications seen on plain film imaging suspicious for visceral artery aneurysms (spleen, kidney, liver or intestines) with ultrasound (CPT® 76700, 76705, 93975, 93976, 93978, or 93979), **or** CTA Abdomen (CPT® 74175), **or** CT Abdomen with contrast (CPT® 74160)
- MRA Abdomen (CPT® 74185) without contrast in place of CTA or CT Abdomen in pediatric individuals or when there is a contraindication to contrast materials (i.e., renal insufficiency, contrast allergy, pregnancy)
- Ultrasound (CPT® 76700,76705, 93975, 93976, 93978, or 93979) **or** CTA Abdomen (CPT® 74175) **or** CT Abdomen with contrast (CPT® 74160) is considered medically necessary for further monitoring based on the intervals below or as determined by a vascular specialist or any provider in consultation with a vascular specialist:
  - Splenic artery aneurysms:
    - <20mm can be imaged every three years
    - 20mm to 29mm can be imaged annually
    - If ≥30mm, they should be referred for treatment, either stent, excision or splenectomy
  - For all other visceral artery aneurysms:
    - Initial evaluation with six-month follow-up for one year
    - Further follow-up annually if no significant enlargement is seen
- CTA Abdomen (CPT® 74175), MRA Abdomen (CPT® 74185), or CT Abdomen with contrast (CPT® 74160) is considered medically necessary following stent placement at:
  - 1 month
  - 6 months
  - 12 months
  - Then every year

Evidence Discussion

Aneurysmal disease, besides primarily involving the large vessels, can also affect medium and smaller sized vessels. Visceral cases are uncommon and occasionally are associated with certain connective tissue and genetic disorders. They are often found incidentally on imaging. Ultrasound, CT, or CTA imaging may be indicated for

Click Here to Return to the Main TOC

surveillance in these cases. Due to the anatomic location of the visceral vessels, duplex ultrasound may have technical limitations. Consideration of best surveillance study should be decided on initial imaging and whether a certain modality is felt to provide diagnostic information. Example; some splenic arterial aneurysms may be diagnostic with US but others may be obscured by bowel gas requiring CT/CTA. Splenic artery aneurysms, the most common (60%), tend to exhibit very slow rates of growth, while the other visceral artery aneurysms are more unpredictable in their rate of growth with a greater tendency to rupture. Visceral Artery Aneurysms are defined by an increase of more than 50% of the original arterial diameter and include hepatic, renal and intestinal artery aneurysms.

Iliac Artery Aneurysm (IAA) (PVD-6.4)

PVD.AD.0006.4.A
v2.0.2026

- Ultrasound (CPT® 76882 or CPT® 93925) is medically necessary for evaluation of a suspected IAA
  - CT Pelvis with contrast (CPT® 72193) if ultrasound is equivocal.
  - Ultrasound for follow-up imaging annually if an aneurysm is ≥2cm
- Additional Imaging
  - CT Abdomen and Pelvis with contrast (CPT® 74177), CT Abdomen and Pelvis without and with contrast (CPT® 74178), or CTA Abdomen and Pelvis (CPT® 74174) is medically necessary for preoperative imaging if endovascular or open repair is being considered

Background and Supporting Information

- Isolated IAA's are rare and are typically associated with AAA
- Approximately one third to one half of isolated IAA's are bilateral at time of presentation
- Abdominal Aortic aneurysm rupture usually occurs at a diameter of 5 cm or larger, whereas common iliac aneurysms that are less than 3 cm in diameter almost never rupture

Evidence Discussion

Annual surveillance of iliac artery aneurysms is medically necessary to determine when intervention is necessary if an iliac aneurysm exceeds 2cm in diameter. Duplex ultrasound is the primary imaging modality for individuals without technical limitations related to body habitus. It has been demonstrated to be accurate, cost-effective and does not use ionizing radiation or contrast. CT imaging may be indicated for cases where ultrasound is equivocal or for surgical planning.

Lower Extremity Artery Aneurysms (PVD-7.4)

PVD.AI.0007.4.A
v2.0.2026

Imaging Indications

Iliac Artery Aneurysm

See **Iliac Artery Aneurysm (IAA) (PVD-6.4)**

Femoral Artery Aneurysm

- Initial imaging is medically necessary as follows:
  - Ultrasound (CPT® 93925 bilateral study or CPT® 93926 unilateral study).
- Surveillance imaging is medically necessary as follows:
  - Asymptomatic true femoral aneurysms smaller than 2.5 cm in diameter
    - Ultrasound (CPT® 93926 unilateral study) annually
  - Asymptomatic true femoral aneurysms larger than 2.5 cm
    - Ultrasound (CPT® 93926 unilateral study) every 6 months
- Other imaging is medically necessary as follows:
  - CTA or MRA Lower extremity (CPT® 73706 or 73725 or 74198 or 75635):
    - Preoperative study for individuals with no plans for invasive angiography
    - Technically limited or abnormal ultrasound results

Popliteal Artery Aneurysm

- Initial imaging is medically necessary as follows:
  - Ultrasound (CPT® 93925 bilateral study or CPT® 93926 unilateral study) and Ultrasound to assess for a contralateral popliteal aneurysm and abdominal aortic aneurysm (CPT® 76770 or CPT® 76775)
- Surveillance imaging is medically necessary as follows:
  - If no intervention: Ultrasound (CPT® 93926 unilateral study) annually
  - Post-intervention: (ABI (CPT® 93922) and Duplex ultrasound are indicated as follows:
    - 3 months post-operative
    - 6 months post-operative
    - 12 months post-operative
    - Then annually

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Other imaging is medically necessary as follows:
  - CTA or MRA (CPT® 73706 or 73725 or 74185 or 75635) for:
    - Preoperative study
    - Technically limited or abnormal ultrasound results

Evidence Discussion

Duplex ultrasound is the preferred modality for surveillance of lower extremity arterial aneurysms. This modality uses no ionizing radiation or contrast, has a reasonable level of accuracy and is cost-effective. CT/MR imaging may be indicated for preoperative planning or in cases where ultrasound is technically limited.

Upper Extremity PVD – Imaging (PVD-4.1)

PVD.AI.0004.1.A
v2.0.2026

Initial Imaging

For arterial insufficiency, arterial ultrasound upper extremities (CPT® 93930 or CPT® 93931) is medically necessary for signs and symptoms of arterial insufficiency including:

- Arm or hand claudication
- Bluish discoloration of the hand or fingers
- Unilateral cold, painful, pulseless hand
- Non-healing wound (>2 weeks with no healing or evidence of healing) or frank gangrene
- CTA Upper extremity (CPT® 73206) or MRA of Upper extremity (CPT® 73225), **and/or** CTA Chest (CPT® 71275) or MRA Chest (CPT® 71555) is medically necessary for:
  - Abnormal arterial ultrasound results
  - Equivocal arterial ultrasound results
  - Pre-operative planning

For Subclavian Steal Syndrome, the following studies are considered medically necessary:

- Carotid duplex (CPT® 93882) is the initial and definitive imaging study.
- CTA chest (CPT® 71275) or MRA chest (CPT® 71555) for carotid duplex showing reversal of flow in one of the vertebral arteries.
- Surveillance of subclavian arterial disease is **not** medically necessary if there has not been any intervention such as a carotid-subclavian bypass or subclavian stent

Note:

If the carotid duplex is not diagnostic for reversal of flow in the ipsilateral vertebral artery, then neurological symptoms should be evaluated according to the Head Imaging guideline

For suspected Fibromuscular Dysplasia of the brachial artery, medically necessary studies include:

- MRA Upper extremity (CPT® 73225)
- CTA Upper extremity (CPT® 73206)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Arterial Ultrasound (CPT® 93930 bilateral study or CPT® 93931 unilateral study)

For arterial thoracic outlet syndrome, medically necessary studies include:

- CTA Chest (CPT® 71275) (preferred study) or MRA Chest (CPT® 71555) (preferred study) or CT Chest either without or with contrast (CPT® 71250 or CPT® 71260) or MRI Chest with contrast (CPT® 71551)

Post-revascularization

- Arterial Duplex (CPT® 93931) is medically necessary following upper extremity arterial revascularization at:
  - Baseline (within one month)
  - 6 months
  - Then annually if stable
  - Anytime for new or worsening symptoms of arterial insufficiency

Evidence Discussion

Upper extremity PVD

Duplex ultrasound (DU) is the initial imaging modality for assessment of patients with symptoms of upper extremity arterial occlusive disease including arm/hand claudication, non-healing wounds, blue discoloration, or a unilateral cold, painful, and pulseless hand.

DU is a non-invasive, cost-effective method for screening for arterial disease of the upper extremity. It has high sensitivity and specificity when compared to CT angiography (CTA) and MR angiography (MRA). CTA and MRA also evaluate anatomic location of disease but are reserved for confirmed vascular disease, suspected fibromuscular dysplasia of the brachial artery, and/or pre-operative planning. They are not first line imaging studies due to the higher risks associated with their use and the cost.

Post-revascularization surveillance with DU has been established as a reliable method to monitor the intervention for recurrence of disease. The time intervals for surveillance have been established at one and six months post-intervention, then yearly. If at any time, there are new signs or symptoms of disease, repeat duplex imaging is supported.

If initial duplex demonstrates high-grade stenosis or occlusion of the subclavian artery, advanced imaging is NOT indicated unless the individual is symptomatic with arm claudication or signs of hypo-perfusion of the vertebral artery with recurrent dizziness.

Subclavian Steal refers to a hemodynamically significant stenosis or occlusion of the subclavian/innominate artery which results in the reversal of blood flow in the vertebral artery (VA). Signs/Symptoms associated with this syndrome include:

- Physical examination with a >15mmHg discrepancy in blood pressure between two arms
- Supraclavicular bruit

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Symptoms of vertebrobasilar insufficiency, including vertigo and limb paresthesia particularly with use of the ipsilateral arm.

Thoracic outlet syndrome (TOS) refers to compression of the neurovascular structures within the thoracic outlet as they pass from the neck and thorax to the axilla.

- There are three types of TOS, neurogenic, arterial and venous.
- Neurogenic TOS refer to Brachial Plexus (PN-4.1) in the peripheral nerve disorders imaging
- Venous TOS refer to **Upper Extremity Venous Imaging (PVD 4.2)**

Renovascular Hypertension/Renal Artery Stenosis (PVD-6.6)

PVD.AI.0006.6.A
v2.0.2026

Initial imaging

- MRA Abdomen (CPT® 74185) or CTA Abdomen (CPT® 74175) or US kidney retroperitoneal (CPT® 76775) and/or Doppler (CPT® 93975, 93976, 93978, or 93979 if expertise is available) are medically necessary when there is documentation of **any** of the following:
  - Individual is adherent to full doses of three blood pressure medications (including a diuretic) yet has still not achieved goal
  - Sudden and persistent worsening of previously controlled hypertension
  - Onset of hypertension younger than 30 years of age
  - Malignant hypertension with coexistent evidence of acute end-organ damage (acute renal failure, new visual or neurological disturbance and/or advanced retinopathy) or flash pulmonary edema
  - Individuals who develop hypertension (≥140/90) within the first 20 weeks of pregnancy when hypertension persists >12 weeks post-partum
  - New or worsening renal function/increasing creatinine (especially after the administration of an ACE inhibitor or with angiotensin receptor blocking agent)
- Carotid duplex (CPT® 93880) is medically necessary to screen for carotid involvement in individuals with documented or highly suspicious renal artery stenosis due to fibromuscular dysplasia (mostly women between 15 and 50 years of age).

Screening

CTA Abdomen (CPT® 74175) or MRA Abdomen (CPT® 74185) is medically necessary to screen for renovascular fibromuscular dysplasia in hypertensive individuals with documented cervicocephalic fibromuscular dysplasia. The assessment of other vascular beds should be considered if supported by suggestive symptoms or medical history.

Carotid duplex (CPT® 93880) is medically necessary to screen for carotid involvement in individuals with documented or highly suspicious renal artery stenosis due to fibromuscular dysplasia (mostly women between 15 and 50 years of age)

Proprietary Information of UnitedHealthcare.

Repeat imaging post revascularization

- CTA Abdomen (CPT® 74175), or MRA Abdomen (CPT® 74185), or CT Abdomen with contrast (CPT® 74160) is medically necessary after stent placement at the following intervals:
  - 1 month post-procedure
  - 6 months post-procedure
  - 12 months post-procedure
  - Then annually

Evidence Discussion

Renovascular Hypertension

The American Heart Association 2017 guidelines on hypertension estimate renovascular disease to be the source of 5-34% of all cases. Multiple studies have shown that intervention is not more effective than medical therapy in most cases as reviewed by the KDIGO conference in 2022; however, it is noted that these recommendations continue to evolve. While duplex ultrasound is the preferred imaging modality, patients with compromised renal function or technical limitations due to body habitus may require CT/MR imaging for monitoring.

Current recommendations for renal artery screening in the setting of hypertension refractory to medical therapy include the following:

- Individual is adherent to full doses of three blood pressure medications (including a diuretic) yet has still not achieved goal
- Sudden and persistent worsening of previously controlled hypertension
- Onset of hypertension younger than 30 years of age
- Malignant hypertension with coexistent evidence of acute end-organ damage (acute renal failure, new visual or neurological disturbance and/or advanced retinopathy) or flash pulmonary edema
- Individuals who develop hypertension (≥140/90) within the first 20 weeks of pregnancy when hypertension persists >12 weeks post-partum o New or worsening renal function/increasing creatinine (especially after the administration of an ACE inhibitor or with angiotensin receptor blocking agent)

Fibromuscular dysplasia carries a higher risk of concomitant renal and carotid artery involvement. Screening of both anatomic regions is medically necessary upon diagnosis.

Post-intervention imaging with CT/MR imaging at standard 1/6/12 month intervals followed by annual imaging to assess for stent patency follow standard recommendations for non-coronary interventions. Additional surveillance is not indicated in the absence of symptoms.

Click Here to Return to the Main TOC

Renal artery revascularization has not been shown to be more effective than medical therapy in most situations and should not be pursued except in extreme cases, or if there is concern for Takayasu arteritis or fibromuscular dysplasia. Gadolinium agents may be contraindicated in individuals with severe renal disease or on dialysis due to the risk of developing nephrogenic systemic sclerosis.

Median Arcuate Ligament Syndrome, Nutcracker Syndrome and other Abdominal Vascular Compression Syndromes (PVD-18)

PVD.AI.0018.A
v2.0.2026

Median Arcuate Ligament Syndrome

Codes included

CPT®	Description
74175	Computed tomographic angiography, abdomen, with contrast material(s), including noncontrast images, if performed, and image post-processing
74185	Magnetic resonance angiography, abdomen, with or without contrast material(s)
93975	Duplex scan of arterial inflow and venous outflow of abdominal, pelvic, scrotal contents and/or retroperitoneal organs; complete study
93976	Duplex scan of arterial inflow and venous outflow of abdominal, pelvic, scrotal contents and/or retroperitoneal organs; limited study

Initial Imaging

- Duplex Doppler Ultrasound of Mesenteric Arteries (CPT® 93975 or 93976) is medically necessary as the initial imaging
- CTA or MRA Abdomen (CPT® 74175 or 74185) is medically necessary for **either**:
  - US results are equivocal
  - Preoperative planning

Repeat Imaging

- Surveillance imaging is **not** medically necessary post-operatively in the absence of abdominal symptoms.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion

A non-atherosclerotic cause of chronic mesenteric ischemia.

Patients are typically younger with an average age range of 30-50 years old and a female to male ratio of 4:1

Patients may have symptoms of postprandial abdominal pain, nausea, vomiting, food aversion, weight loss. Symptoms are nonspecific, so MALS may be considered a diagnosis of exclusion.

Imaging will demonstrate compression of the celiac artery by fibers of the median arcuate ligament, but this is a nonspecific finding and may be seen in the asymptomatic population.

Pathophysiologically related to foregut ischemia from compression of the celiac artery; may also be related to neuropathic pain secondary to compression of the celiac ganglion.

Treatment is generally surgical, via a variety of approaches.

Left Renal Vein Compression ("Nutcracker") Syndrome

Codes included

CPT®	description
93975	Duplex scan of arterial inflow and venous outflow of abdominal, pelvic, scrotal contents and/or retroperitoneal organs; complete study
93976	Duplex scan of arterial inflow and venous outflow of abdominal, pelvic, scrotal contents and/or retroperitoneal organs; limited study
74174	Computed tomographic angiography, abdomen and pelvis, with contrast material(s), including noncontrast images, if performed, and image post-processing
72198	Magnetic resonance angiography, pelvis, with or without contrast material(s)
74185	Magnetic resonance angiography, abdomen, with or without contrast material(s)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Initial Imaging

- Abdominal duplex (CPT® 93975 or 93976) is medically necessary as the initial imaging to confirm left renal vein compression syndrome.
- CTV or MRV Abdomen and Pelvis (CPT® 74174) or (CPT® 74185 and 72198) is medically necessary for preoperative planning when left renal vein compression syndrome is confirmed by duplex ultrasound.

Repeat imaging

- Postoperative follow-up imaging is **not** medically necessary in the absence of symptomatology.

Background and Supporting Information

Patients may present with symptoms related to compression of the left renal vein between the aorta and superior mesenteric artery. A less common presentation ("posterior nutcracker syndrome") is related to compression of a retroaortic (or circumaortic) left renal vein between the aorta and vertebral body.

The radiologic finding may be asymptomatic or considered a normal variant.

Signs/symptoms may include hematuria, proteinuria, flank pain, pelvic congestion/ associated pain in females, varicocele in males.

There may be an overlap in symptom complex with patients who have pelvic congestion syndrome, iliac vein compression (May-Thurner).

There is no single accepted treatment modality. Approaches will range from conservative/medical (esp in younger patients), to endovascular, to open/laparoscopic/ robotic surgical.

Claudication and Critical Limb Ischemia (PVD-7.1)

PVD.AI.0007.1.A
v2.0.2026

- Resting ABI for initial evaluation of suspected PAD. This can be accomplished at the bedside as part of the physical examination or requested as CPT® 93922 (limited Doppler ultrasound) or CPT® 93923 (multi-level complete Doppler ultrasound)
  - CPT® 93923 is medically necessary once
  - Follow-up studies are medically necessary with CPT® 93922
  - Post-exercise ABI (CPT® 93924) is medically necessary if the resting ABI is >0.89 and PAD is still highly suspected clinically.
- History and physical suggestive of PAD include:
  - History
    - Claudication- reproducible calf or thigh cramping with exertion that is relieved completely with rest
    - Critical limb ischemia
    - Rest pain suggestive of ischemia-pain in the ball of foot when the leg is in an elevated position particularly at night
    - Distal non-healing wound or punched out ulcer with sharply demarcated edges present for >2 weeks with no evidence of healing, i.e. presence of granulation tissue
  - Physical Examination
    - Abnormal lower extremity pulse examination
    - Vascular bruit
    - Non-healing lower extremity wound
    - Lower extremity gangrene
    - Other suggestive lower extremity physical findings (e.g., elevation pallor/ dependent rubor)
    - Atrophic nails, hair loss, shiny skin
- If resting ABI (CPT® 93922) is normal (0.9 to 1.3) and disease is still suspected:
  - Differentiate from “pseudoclaudication”. See **Lumbar Spinal Stenosis (SP-9)** in the Spine Imaging Guidelines
  - Re-measure ABI after exercise (CPT® 93924)
  - A TBI (toe-brachial index) may be used as further screening in individuals with ABI’s ≥1.4
  - Advanced imaging is medically necessary only if there is consideration for invasive therapy not to confirm diagnosis

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Duplex ultrasound (CPT® 93925 bilateral study or CPT® 93926 unilateral study) and Doppler studies are adjuncts to abnormal ABI that are considered medically necessary to identify location and extent of disease once there has been a decision for revascularization.
- MRA Aorta and Pelvic vessels, and Lower extremities (CPT® 74185, CPT® 73725 and CPT® 73725), or CTA with run-off (CPT® 75635) are medically necessary to further evaluate the lower extremity arteries for ANY of the following:
  - Potentially limb-threatening vascular disease evidenced by:
    - Skin breakdown
    - Non-healing ischemic ulcers
    - Resting leg pain
    - Gangrene
  - Blue Toe Syndrome:
    - Emboli from aortic plaque or mural thrombus
    - Hyperviscosity syndrome
    - Hypercoagulable states
    - Vasculitis
  - Preoperative planning for Intermittent claudication (i.e., non-limb threatening ischemia) AND there is documentation of both of the following:
    - Failed 3-months' conservative medical therapy (physician supervised walking/ exercise program plus medical therapy)
    - Functional disability (e.g., exercise impairment sufficient to threaten the individual's employment or to require significant alterations in the individual's lifestyle)
  - CTA lower extremity (CPT® 73706) OR MRA lower extremity (CPT® 73725) is medically necessary for evaluation of PVD when aortoiliac disease is not a concern or the state of the aorta and iliac arteries is already known as documented in the clinical history

Note:

MRA Pelvis (CPT® 72198) should not be requested/billed with CPT® 74185, CPT® 73725 and CPT® 73725

- To evaluate for an embolic source, the following studies are medically necessary:
  - CTA chest (CPT® 71275) OR MRA Chest (CPT® 71555) AND
  - CTA Abdomen and Pelvis (CPT® 74174) OR MRA Abdomen and Pelvis (CPT® 74185) (if imaging of abdomen/pelvis not already obtained)

    See also Echocardiogram in the Cardiac imaging guideline

Evidence Discussion

Peripheral arterial disease (PAD) is defined as chronic, atherosclerotic occlusive disease of the lower extremities. The vast majority of patients with PAD are asymptomatic. A much smaller group has symptomatic PAD, consisting of intermittent claudication(IC), rest pain or tissue loss.

The natural history of PAD for asymptomatic and IC patients is relatively benign. It is estimated that 7% (4%–11%) of asymptomatic patients deteriorate to IC over a 5-year period. Multiple studies have established that patients with IC are at very low risk of major amputation (<1% per year).

For these reasons, the first line of treatment for patient with IC is risk factor reduction/ modification and exercise therapy. A meta-analysis of 1200 patients determined that exercise therapy, compared with placebo or usual care, provides an overall improvement in walking ability of 50% to 200%, with improvements maintained for up to 2 years. Additionally, with intensive medical management, <5% of patients will develop symptoms of advanced ischemia, such as ischemic rest pain, tissue loss, or require amputation.

Diagnosis:

Measurement of the ankle-brachial index (ABI) is the primary method for establishing the diagnosis of PAD. An ABI of 0.90 has been demonstrated to have high sensitivity and specificity for the identification of PAD compared with the gold standard of conventional angiography (CA). It is a simple non-invasive method to assess for PAD. It avoids use of radiation, and contrast agents. It can be performed easily in an office setting and is cost-effective.

Further studies for evaluation of anatomic location of disease are warranted if PAD is proven. Arterial duplex combines Doppler spectral analysis and B-mode imaging to evaluate blood flow and anatomy. It has been shown to be effective in localizing arterial vascular disease with comparable sensitivity and specificity to CT angiography (CTA), MR angiography (MRA) and CA. It is also non-invasive, cost-effective, and avoids radiation and contrast exposure.

Due to their associated risks, CTA, MRA and CA should be reserved for patients in whom revascularization treatment is being considered. CTA risks include exposure to intravenous contrast and radiation. Contrast complications include allergy and contrast induced nephropathy. MRA risk includes exposure to gadolinium which confers the risk of nephrogenic systemic fibrosis in patients with renal insufficiency. MRA also is contraindicated in patients with metallic implants. CA risks include radiation and contrast exposure as well as access site complications. Since it is an invasive procedure, there is risk for arterial injury, embolization and thrombosis.

Popliteal Artery Entrapment Syndrome (PVD-7.2)

PVD.AI.0007.2.A
v2.0.2026

- Diagnosis of popliteal artery stenosis or occlusion due to compression by adjacent muscle and tendons all of the following are medically necessary:
  - Resting ABI (CPT® 93922 OR 93923) AND/OR Post-Exercise ABI (CPT® 93924) AND
  - Ultrasound (CPT® 93926 unilateral study) AND
  - Either CTA Lower extremity (CPT® 73706), or MRA Lower extremity (CPT® 73725).
  - CT or MRI Lower Extremity (contrast as requested) if requested by the operating surgeon

Evidence Discussion

Popliteal Artery Entrapment

Popliteal artery entrapment syndrome is a nonatheromatous cause of lower extremity ischemic symptoms. It is caused by abnormal embryologic development of the structures in the popliteal fossa. The symptoms are caused by compression of the popliteal artery by the muscles or fibrous bands. The typical presentation is claudication symptoms in physically active young men who have normal pulse examination.

Popliteal Artery Entrapment Syndrome is typically seen in young men (ages 20 to 40) but is not exclusive to this gender or age group.

Due to its unusual nature and presentation, ultrasound, CT Angiography or MR Angiography of the lower extremity is supported for diagnosis. Since it is critical to understand the anatomic relationships of the muscles to the vessels in the popliteal fossa, CT or MRI of the lower extremity is supported if requested by the surgeon for pre-operative planning.

Arterial Imaging for Free Flaps in Reconstructive Surgery (PVD-7.5)

PVD.AI.0007.5.A
v2.0.2026

Indications

- Breast reconstruction preoperative planning: See **Breast Reconstruction (BR-3)** in the Breast Imaging Guidelines
- Head and neck reconstruction: CTA or MRA unilateral lower extremity (CPT® 73706 or 73725) of the harvest site is medically necessary to evaluate perforator anatomy for planned fibular flap
  - Bilateral imaging is medically necessary when requested from the operating surgeon to select harvest site

Arteriovenous Malformations (AVMs) (PVD-9.1)

PVD.AI.0009.1.A
v2.0.2026

- See **Pulmonary AVMs (CH-24.1)** in the Chest Imaging Guidelines
- See **Arteriovenous Malformations (AVMs) and Related Lesions (HD 12.2)** in the Head Imaging Guidelines
- See **Arteriovenous Malformations (AVMs) and Fistulas (PEDPVD-2.5)** in the Pediatric Peripheral Vascular Disease Imaging Guidelines
- See **Pelvic Pain/Dyspareunia, Female (PV-11.1)** in the Pelvis Imaging Guidelines

Initial imaging

- Ultrasound with Doppler is medically necessary as an initial examination for superficial lesions in the limbs.
  - Large lesion characterization may be limited by ultrasound imaging window.
  - Ultrasound is also limited in evaluating AVM relationship to airway or bony structures.

Evaluation and surveillance

- MRI without contrast or without and with contrast of the affected body part is the study of choice for abdominal AVMs and deep tissue (below the skin) AVM's in the limbs.
- MRA (contrast as requested) of the affected body part is medically necessary for evaluation and surveillance of known AVMs.
- It is unusual for both MRI and MRA to be necessary for routine treatment response or surveillance imaging of AVMs, but both may be approved for preoperative planning.
- CT and CTA can also be used to characterize AVMs and their relationship to normal structures but is generally not better than MRI and has associated radiation risks.
  - CT with contrast and/or CTA (contrast as requested) of the affected body part is medically necessary when MRI and/or MRA is inconclusive or contraindicated.

Post-embolization

- Advanced imaging is medically necessary one-time post-embolization to evaluate for successful resolution of the AVM.
- Additional imaging (same study performed pre-procedure or as requested by the treating provider) is medically necessary for treatment planning purposes if resolution of the AVM was not achieved.

Background and Supporting Information

Arteriovenous malformations are characterized by a network of multiple abnormal vascular channels interposed between enlarged feeding arteries and draining veins. The arteriovenous fistula has a single communication interposed between a feeding artery and a draining vein. The normal capillary bed is absent in both lesions. Both lesions may have an aggressive clinical course and are characterized by a reddish pulsatile mass which has a thrill or bruit. Though often recognized at birth, these lesions may grow and present near adolescence.

Vascular Graft Infection (PVD-21)

PVD.PA.21.A
v2.0.2026

Suspected or Known Vascular Graft Infection

Clinical concern for vascular graft infection

Imaging of the affected vascular segment is considered medically necessary for the diagnosis of suspected vascular graft infection and/or treatment planning for known vascular graft infection as follows:

- Duplex arterial ultrasound and/or CTA or MRA of the affected arterial segment.
- CTA or MRA of proximal and/or distal vascular beds of the affected segment for operative planning as requested by the surgeon (or provider in consultation with the performing surgeon).
- Indium 111 (111In)–labeled white blood cell (WBC) or Gallium-67 citrate studies (CPT® 78800, CPT® 78801, CPT® 78802, or CPT® 78803)
- PET/CT (CPT® 78815) for clinical suspicion of aortic infection (graft or native aorta) when **both** of the following apply:
  - CT-angiogram is equivocal/indeterminate AND
  - Indium-111 or Gallium-67 studies have not been performed **and** are not available or not technically feasible.

Evidence Discussion

Infection of vascular grafts is uncommon but serious and potentially life-threatening. Clinical presentations are variable, and imaging may be necessary to identify and/or define extent of infection, as well as for surgical planning.

Ultrasound is an inexpensive imaging modality that may identify findings associated with infection, such as fluid collections and pseudoaneurysm. This method is a considered a reasonable first-line modality to image extracavitary infection, but utility in evaluating intracavitary grafts and associated infection is limited.

CTA is a commonly used modality to evaluate intracavitary grafts, but is also useful in evaluating extracavitary graft, especially for surgical planning. Disadvantages include contrast exposure, and limited sensitivity/specificity.

MRI may also be useful in evaluating vascular grafts and allows for good soft tissue resolution. Disadvantages include generally higher cost than CT scan, longer acquisition

Click Here to Return to the Main TOC

times, and limitations in use when patients have intracardiac devices and/or renal disease.

WBC scintigraphy, as well as PET/CT scan, allow for more definitive identification of infection, compared with CT scans. WBC scintigraphy may be limited due to the time needed for the study; while PET/CT may be limited due to low specificity.

Imaging for Hemodialysis Access (PVD-8)

PVD.AI.0008.0.A
v2.0.2026

Arterial Evaluation and Venous Mapping Prior to AV Fistula (PVD-8.1)

- Imaging prior to AV fistula creation is medically necessary:
  - For vessel mapping CPT® 93985 or 93986
  - MRA Upper Extremity (CPT® 73225) may be needed if duplex imaging is equivocal
- Arterial evaluation to assess arterial suitability (size, degree of stenosis and calcification) prior to AV fistula creation is medically necessary as follows:
  - CPT® 93930 or CPT® 93931 can be used to report upper extremity arterial evaluation
- Venous mapping (CPT® 93970 or CPT® 93971) is medically necessary to assess venous suitability prior to AV fistula creation

Hemodialysis access imaging (PVD-8.2)

- Indications for Duplex ultrasound (CPT® 93990) of hemodialysis access include but are not limited to:
  - Individuals with decreased flow rates during hemodialysis.
  - Development of arm swelling or discomfort after access placement surgery or a hemodialysis session.
  - Prolonged immaturity of a surgically created AV fistula.
  - Suspected pseudoaneurysm.
  - Suspected AV fistula or graft stenosis.
  - Known or suspected fluid collection adjacent to an AV fistula or graft.
  - One Duplex US (CPT® 93990) can be performed after a surgically created AV fistula for assessment, although it is not generally needed.
- Central venous stenosis can cause new dialysis access to fail to mature or cause the premature failure of existing fistulas/grafts.
- CT Chest with contrast (CPT® 71260), or CTA Chest (CPT® 71275), or MRA Chest (CPT® 71555) is medically necessary when there is documentation of either:
  - Signs and symptoms of central venous stenosis including:
    - Arm swelling
    - Presence of numerous collateral veins

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

    - Prolonged bleeding from dialysis puncture sites
  - A history of pacemaker placement or previous tunneled dialysis graft, regardless of signs and symptoms.

Evidence Discussion

Hemodialysis Access for creation and maintenance

Hemodialysis access imaging is required to assess options for creation of hemodialysis access as well as to evaluate for maturation, failure and complications related to the access and outflow central veins.

Prior to creation of a native arteriovenous fistula (AVF), venous duplex ultrasound should be performed of both upper extremities to assess for adequate vein for fistula creation on all patients. Vessel mapping should include arterial inflow assessment to assess size, degree of stenosis and areas of calcification that may exclude access creation. Advanced imaging (CT or MR) of the chest or upper extremity may be indicated to further assess abnormalities identified on duplex imaging or evidence of central venous outflow obstruction.

Duplex evaluation of hemodialysis access should be performed for patients with evidence of failed maturation, poor function of access or complication related to the use of the hemodialysis access by history, physical exam or functional parameters during dialysis. These parameters may include: elevated venous pressures, inefficient dialysis, and recirculation greater than 10-15% or decreased flow.

CT or MR of the chest may be indicated for patients with a history of central venous catheters or pacemaker/ICD wires, signs and symptoms of ipsilateral central venous stenosis including arm swelling, venous collaterals or prolonged bleeding after dialysis.

IVC filters – Treatment (PVD-16.2)

PVD.VI.0016.A
v2.0.2026

- Prior to IVC filter insertion
  - An initial venous duplex is medically necessary to assess for the presence of thrombus in the femoral vein which would affect the approach (transjugular or transfemoral)
- For consideration of removal, CT or CTA Abdomen and Pelvis (CPT® 74177 or, 74174) is medically necessary for **any** of the following:
  - A KUB demonstrates tilting of the filter or malposition of one of the filter thongs
  - New bilateral lower extremity swelling (venous duplex should be performed first)
  - Filter present for >12 months, with documentation stating intent to remove

Background and Supporting Information

- IVC filters are placed in individuals with known DVT that cannot be anti-coagulated, individuals with poor pulmonary reserve and high risk for DVT, or prophylaxis in trauma and surgical individuals.
- Most IVC filters inserted are retrievable and should be removed as soon as clinically feasible. After 12 months, removal of IVC filters can become technically more difficult.

Post iliac vein stenting/angioplasty (PVD-17.1)

PVD.VI.0017.A
v2.0.2026

Iliac venous stents can be placed after thrombolysis for DVT associated with May-Thurner's syndrome, DVT associated with extrinsic compression or for post thrombotic iliac obstruction.

- Arterial duplex (CPT® 93975, 93976, 93978, 93979) are medically necessary for:
  - Surveillance of iliac venous stents
  - Worsening signs or symptoms including increased edema when stent malfunction is suspected
  - Post-operatively within the first month, at six months, twelve months and then annually
- CTV or MRV Abdomen and Pelvis are medically necessary for an abnormal or indeterminate duplex

Upper Extremity Venous – Imaging (PVD-4.2)

PVD.AI.0004.1.A
v2.0.2026

Venous Insufficiency

- For symptoms of venous insufficiency including but not limited to unilateral pain and swelling of the upper extremity
  - Venous duplex upper extremities (CPT® 93970 or CPT® 93971) is medically necessary initially
  - If duplex ultrasound is non-diagnostic, the following studies are medically necessary:
    - MRV Upper extremity (CPT® 73225) and/or MRV Chest (CPT® 71555), or
    - CTV Upper extremity (CPT® 73206) and/or CTV Chest (CPT® 71275)
      - For venous thoracic outlet syndrome, CTV Upper extremity (CPT® 73206) or MRV Upper extremity (CPT® 73225), and/or CTV Chest (CPT® 71275) or MRV Chest (CPT® 71555).
- CT Chest with contrast (CPT® 71260) is medically necessary for Superior Vena Cava Syndrome (upper extremity and facial symptoms).
- **Either** of the following is medically necessary when stenting of the SVC is being considered:
  - MRV Chest (CPT® 71555)
  - CTV Chest (CPT® 71275)

Lymphedema of the Upper extremity

When initial imaging with venous duplex has ruled out DVT, **either** of the following studies are medically necessary to evaluate for suspected lymphedema of the upper extremity:

- Lymphoscintigraphy (CPT® 78195)
- MR lymphangiography (CPT® 75801)

Evidence Discussion

Upper Extremity Venous Imaging

Duplex ultrasound is the initial imaging modality for assessment of patients with symptoms of upper extremity venous occlusive disease or venous insufficiency including arm edema, pain and ulceration. Duplex imaging is limited in assessment of the proximal subclavian vein and central veins due to anatomic interference by the rib

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

cage and lungs. MRV or CTV is medically necessary to assess these more proximal segments of the venous outflow and central venous structures including the innominate veins and SVC.

Advanced imaging is medically necessary for treatment planning in SVC syndrome and proximal venous intervention. Follow-up imaging after PTA and/or stenting for SVC syndrome or proximal vein occlusive disease may be approved assessment of stent patency and for recurrent symptoms.

SVC syndrome is caused by acute or subacute, intrinsic or extrinsic obstruction of the SVC, (ex: lung cancer, fibrosis, indwelling catheters/devices, thrombus). Other symptoms include dyspnea, headache and dizziness.

Thoracic Outlet Syndrome (TOS) refers to compression of the neurovascular structures within the thoracic outlet as they pass from the neck and thorax to the axilla. There are three types of TOS, neurogenic (see Brachial plexus-PN 4.1), venous and arterial (see Upper Extremity PVD-PVD 4.1). Venous TOS typically occurs in young athlete after a history of exertion of the limb, or in the presence of a central venous catheter which traverses the subclavian vein.

Lymphedema is caused by dysfunction of the lymphatic system. Primary lymphedema is a result of a congenital malformation of the lymphatic system, whereas secondary lymphedema is due to an exogenous cause that impairs the lymphatic system. Typical etiologies include trauma, chronic infection, cancer treatments including lymph node dissections and radiation therapy. Most cases of secondary lymphedema of the upper extremity are related to breast cancer and it's treatment. Due to the anatomic disruption of the lymphatic system, there is accumulation of protein-rich interstitial fluid, persistent swelling and later fibro-adipose hypertrophy.

Acute Limb Swelling (PVD-12)

PVD.VI.0012.A
v2.0.2026

Superficial venous thrombosis (SVT) (PVD-12.1)

- The diagnosis of superficial venous thrombosis is generally made on the basis of physical examination.
  - Duplex ultrasound (CPT® 93970, CPT® 93971) is medically necessary as the initial imaging if the diagnosis is equivocal
  - Follow-up duplex ultrasound (CPT® 93970, CPT® 93971) is medically necessary only if thrombus in the superficial systems is encroaching onto the deep venous system (saphenofemoral or saphenopopliteal junction)

Background and Supporting Information

Superficial venous thrombosis (SVT) refers to acute or chronic thrombosis of the superficial veins in both the upper (cephalic and basilic veins) and lower extremities (greater [great] saphenous vein, lesser [small] saphenous vein). Treatment: Elevation and warm compresses until pain and swelling subsides.

Acute deep venous thrombosis (DVT) (PVD-12.2)

- Duplex ultrasound (CPT® 93970 bilateral study or CPT® 93971 unilateral study) is medically necessary as the initial imaging study for any suspected DVT
  - Deep venous thrombosis can present as
    - Symptomatic
      - Swelling
      - Pain
      - Warmth
      - Erythema
      - Pain with dorsiflexion of the foot (Homan's Sign)
      - Or with progression, such as phlegmasia cerulean dolens
      - Risk factors for DVT include age >40, obesity, malignancy, prolonged immobilization, hypercoagulability as well as those outlined in **Pulmonary Embolism (PE) (CH-25)** in Chest Imaging Guidelines.
- CTA/CTV Abdomen and pelvis with contrast are medically necessary to rule out IVC thrombus secondary to the filter when there is acute bilateral lower extremity swelling in an individual with a history of an IVC filter in place.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- When there is concern for proximal DVT (iliofemoral):
  - Focused abdominal duplex can generally visualize the iliac veins and IVC to determine the absence or presence of iliac vein thrombus in an individual. If the results are equivocal or indeterminate:
    - CTV or MRV Abdomen and Pelvis with contrast (CPT® 74174 or CPT® 74185 and 73725) is medically necessary.
- For request concerning abdominal vein thrombosis, see **Abdominal Veins other than Hepatic and Portal Veins (AB-43.2)** in the Abdomen Imaging Guidelines
- For proximal DVT's (iliac vein DVT's or in cases of phlegmasia (extensive DVT compromising arterial inflow), thrombectomy (rarely performed) or thrombolysis is medically necessary.
- If the cause of the DVT is found to be due to May-Thurner, see also **May-Thurner Syndrome (PVD-13.3)**

Background and Supporting Information

Deep venous thrombosis is characterized by thrombosis of a deep vein in either the upper (brachial, axillary, subclavian veins) or the lower extremity (soleus muscle veins, gastrocnemius muscle veins, peroneal, posterior tibial, popliteal, femoral or iliac veins).

Follow-up imaging of known DVT (PVD-12.3)

- A repeat duplex ultrasound (CPT® 93970 bilateral study or CPT® 93971 unilateral study) is medically necessary in order to rule out proximal extension of a calf vein DVT in individuals who cannot be anticoagulated as follows:
  - One week after the initial diagnosis.
  - Serial imaging (up to 3 studies) over the first three weeks if calf DVT is not treated.
- Evidence does not support the use of imaging during long-term anticoagulation therapy to determine venous recanalization or for the purpose of determining whether or not to continue anticoagulation therapy.

Follow-up imaging after venous surgery (PVD-12.4)

- Venous duplex (CPT® 93971 unilateral study) of the treated limb is medically necessary to rule out a DVT within seven days of endovenous ablation.
- Follow-up routine imaging is **not** medically necessary after other venous procedures including:
  - Saphenous vein ligation and stripping
  - Phlebectomy
  - Sclerotherapy

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Generalized bilateral lower extremity edema (PVD-12.5)

Bilateral lower extremity edema is multifactorial. Prior to any request for advanced imaging, a workup for causes of the edema should be instituted including echocardiogram to rule out congestive heart failure and laboratory studies to exclude renal insufficiency and liver disease. The following imaging is medically necessary based on the suspected cause of the edema:

- Suspected abdominal or pelvic pathology
  - Abdominal ultrasound or duplex is the initial imaging
  - CT Abdomen and Pelvis or CT pelvis either with or without contrast can be performed if abdominal US is equivocal or indeterminate
- Suspected chronic venous insufficiency
  - A venous duplex CPT® 93970 (bilateral) or CPT® 93971 (unilateral) is medically necessary to evaluate for venous reflux.
- Suspected lymphedema
  - When initial noninvasive studies, such as ultrasound, are negative for venous valvular insufficiency **either** of the following advanced imaging studies is indicated:
    - Lymphoscintigraphy (CPT® 78195)
    - MRI lymphangiography (CPT® 73718)

Unilateral lower extremity edema (PVD-12.6)

Initial imaging for unilateral lower extremity edema with duplex ultrasound (CPT® 93971, unilateral study) is medically necessary.

- If there is concern for proximal DVT:
  - focused abdominal duplex to evaluate the iliac veins and IVC
  - CTV or MRV Abdomen and Pelvis (CPT® 74174 or CPT® 74185 and CPT® 72198) for indeterminate or equivocal duplex results.
- If there is concern for abdominal or pelvic pathology:
  - Abdominal/pelvic ultrasound or duplex
  - CT Abdomen and Pelvis, or CT Pelvis with or without contrast if the abdominal ultrasound is indeterminate or inconclusive

Background and Supporting Information

Unilateral edema favors localized causes of venous or lymphatic compromise, rather than systemic etiologies which tend to result in bilateral edema. Initial imaging is duplex ultrasound. This can assess for vascular and non-vascular causes, including DVT, venous reflux, popliteal cysts, hematoma, mass.

Chronic limb swelling due to chronic deep venous thrombosis (DVT)/May-Thurner syndrome (PVD-13)

PVD.VI.0013.A
v2.0.2026

Chronic DVT with incompletely lysed or residual DVT (PVD-13.1)

Individuals with incompletely lysed or residual DVT can develop post-thrombotic syndrome that can be characterized as chronic edema, venous stasis changes, pain and in advanced cases venous stasis ulceration.

- Imaging is medically necessary to evaluate for iliac venous obstruction from incompletely lysed thrombus in individuals with a history of proximal (iliofemoral) DVT who have developed post thrombotic syndrome.
  - Initial imaging is duplex (CPT® 93970 bilateral study or CPT® 93971 unilateral study)
  - Either a CTV or MRV Abdomen and Pelvis (CPT® 74174) or (CPT® 74185 and 72198) OR CTV Pelvis (CPT® 72191) or MRV Pelvis (CPT® 72198), or venography for treatment planning purposes.
- Imaging for post-thrombotic syndrome is only medically necessary for **either**:
  - Signs and symptoms suggestive of a new acute DVT
  - Preoperative planning for iliac vein/stenting for suspected iliac vein stenosis or occlusion

Background and Supporting Information

- Chronic deep venous thrombosis is defined as an acute DVT that is greater than 14 days old.
- Incompletely lysed DVT can cause luminal narrowing of the vein restricting venous outflow leading to stenosis or occlusion and /or can lead to valve dysfunction resulting in reflux of venous blood retrograde towards gravity. Both pathologies ultimately lead to chronic edema which can cause chronic pain and venous stasis disease.
  - The mainstay of treatment for chronic deep venous thrombosis is compression stockings
  - Selected individuals may be a candidate for iliac vein angioplasty/stenting.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Post-thrombotic syndrome (PVD-13.2)

- Imaging for post-thrombotic syndrome is medically necessary when:
  - There are signs and symptoms suggestive of a new acute DVT
  - For preoperative planning for iliac vein/stenting in the setting of known iliac venous obstruction in those with a history of a proximal (iliofemoral) DVT.
- Imaging for post-thrombotic syndrome is NOT medically necessary for chronic swelling that has not changed in severity or character

May-Thurner syndrome (PVD-13.3)

- CTV or MRV Abdomen and Pelvis (CPT® 74174, or 74185 and 72198) OR CTV Pelvis or MRV Pelvis (CPT® 72191 or 72198) is medically necessary in individuals with a history of **one** of the following:
  - Left lower extremity iliac DVT
  - Persistent left lower extremity edema OR varicose veins OR venous stasis ulcer despite treatment of superficial venous disease in that extremity
  - Persistent left lower extremity edema OR varicose vein OR venous stasis ulcer in the absence of saphenous vein reflux.
- Imaging and/or prophylactic treatment of May-Thurner syndrome, in the absence of acute or chronic DVT **or** chronic left lower extremity edema and its sequelae such as varicose veins or venous stasis ulcers, is **not** considered medically necessary

Background and Supporting Information

In approximately 25% of people, the right iliac artery overlies the left iliac vein over the fifth lumbar vertebrae and its pulsations can compress the vein increasing the risk of DVT in the left extremity.

- Treatment is with iliac vein angioplasty/stenting

Pelvic congestion syndrome (PVD-13.4)

- Signs and symptoms of pelvic congestion syndrome include:
  - Chronic pelvic pain OR post-coital discomfort >6 months.
  - Associated symptoms can include the presence of labial varicosities or heavy menstrual periods.
- Initial imaging is via transvaginal or pelvic ultrasound to exclude other pathologies of chronic pelvic pain
- CTV or MRV Abdomen and Pelvis (CPT® 74174, or 74185 and 72198) is medically necessary if initial ultrasound is inconclusive or non-diagnostic.

Proprietary Information of UnitedHealthcare.

Evidence Discussion

Chronic limb swelling due to chronic deep venous thrombosis (DVT)/ May-Thurner syndrome, post-thrombotic syndrome and pelvic congestion syndrome

For patients with isolated left leg edema, or left leg edema greater than right leg, duplex ultrasound of the extremity should be performed to assess for DVT. If femoral DVT is identified, duplex ultrasound of the pelvis should be performed to assess for iliocaval DVT or evidence of a mass that may be causing compression of the iliac vein or IVC.

In patients with acute iliofemoral DVT, advanced imaging with either CTV or MRV of the abdomen and or pelvis is medically necessary for cases of iliofemoral DVT identified on ultrasound for treatment planning, or cases where iliofemoral DVT or stenosis is suspected but pelvic ultrasound is indeterminate or limited due to body habitus or overlying bowel gas obscuring the iliac vein.

Advanced imaging with CTV or MRV of the abdomen and/or pelvis is medically necessary in patients without acute DVT but a prior history of left iliac DVT or leg edema, varicosities or venous stasis disease in the absence of underlying venous insufficiency or following treatment of superficial venous insufficiency to assess for iliac vein compression. Post-Thrombotic syndrome due to prior DVT and subsequent deep venous insufficiency may lead to recurrent or chronic lower extremity edema. Management is compression therapy and advanced imaging is only indicated for assessment of symptoms consistent with new iliofemoral DVT or for preoperative planning for identified iliac vein stenosis.

Advanced imaging with CTV or MRV is medically necessary in patients with recurrent symptoms and a history of iliocaval stenting for iliac vein DVT, or compression.

Pelvic congestion syndrome may be a cause of chronic pelvic pain or post-coital discomfort. Initial imaging is pelvic or transvaginal ultrasound to assess for other sources of pelvic pain. Advanced imaging such as CTV or MRV of the abdomen and pelvis is medically necessary if ultrasound is inconclusive or non-diagnostic or for treatment planning.

MRI/MRA	CPT®
Magnetic resonance spectroscopy, determination and localization of discogenic pain (cervical, thoracic, or lumbar); acquisition of single voxel data, per disc, on biomarkers (ie, lactic acid, carbohydrate, alanine, laal, propionic acid, proteoglycan, and collagen) in at least 3 discs	0609T
Magnetic resonance spectroscopy, determination and localization of discogenic pain (cervical, thoracic, or lumbar); transmission of biomarker data for software analysis	0610T
Magnetic resonance spectroscopy, determination and localization of discogenic pain (cervical, thoracic, or lumbar); postprocessing for algorithmic analysis of biomarker data for determination of relative chemical differences between discs	0611T
Magnetic resonance spectroscopy, determination and localization of discogenic pain (cervical, thoracic, or lumbar); interpretation and report	0612T

CT	CPT®
CT Cervical without contrast	72125
CT Cervical with contrast (Post-Myelography CT)	72126
CT Cervical without and with contrast	72127
CT Thoracic without contrast	72128
CT Thoracic with contrast (Post-Myelography CT)	72129
CT Thoracic without and with contrast	72130
CT Lumbar without contrast (Post-Discography CT)	72131
CT Lumbar with contrast (Post-Myelography CT)	72132
CT Lumbar without and with contrast	72133

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

CT	CPT®
CT Pelvis without contrast	72192
CT Pelvis with contrast	72193
CT Pelvis without and with contrast	72194

Ultrasound	CPT®
Spinal canal ultrasound	76800

Nuclear Medicine	CPT®
Bone Marrow Imaging, Limited	78102
Bone Marrow Imaging, Multiple	78103
Bone Marrow Imaging, Whole Body	78104
Bone or Joint Imaging, Limited	78300
Bone or Joint Imaging, Multiple	78305
Bone Scan, Whole Body	78306
Bone Scan, 3 Phase Study	78315
Radiopharmaceutical localization of tumor, inflammatory process or distribution of radiopharmaceutical agent(s) (includes vascular flow and blood pool imaging, when performed); planar, single area (e.g., head, neck, chest, pelvis), single day imaging	78800
Radiopharmaceutical localization of tumor, inflammatory process or distribution of radiopharmaceutical agent(s) (includes vascular flow and blood pool imaging, when performed); planar, 2 or more areas (e.g., abdomen and pelvis, head, and chest), 1 or more days imaging or single area imaging over 2 or more days	78801

Proprietary Information of UnitedHealthcare.

Nuclear Medicine	CPT®
Radiopharmaceutical localization of tumor, inflammatory process or distribution of radiopharmaceutical agent(s) (includes vascular flow and blood pool imaging, when performed); planar, whole body, single day imaging	78802
Radiopharmaceutical localization of tumor, inflammatory process or distribution of radiopharmaceutical agent(s) (includes vascular flow and blood pool imaging, when performed); tomographic (SPECT), single area (e.g., head, neck, chest, pelvis), single day imaging	78803
Radiopharmaceutical localization of a tumor, inflammatory process, or distribution of radiopharmaceutical agents, including vascular flow and blood pool imaging when performed, planar, whole body, requiring two or more days of imaging	78804
Radiopharmaceutical localization of tumor, inflammatory process or distribution of radiopharmaceutical agent(s) (includes vascular flow and blood pool imaging, when performed); tomographic (SPECT) with concurrently acquired computed tomography (CT) transmission scan for anatomical review, localization and determination/detection of pathology, single area (e.g., head, neck, chest, pelvis), single day imaging	78830
Radiopharmaceutical localization of tumor, inflammatory process or distribution of radiopharmaceutical agent(s) (includes vascular flow and blood pool imaging, when performed); tomographic (SPECT), minimum 2 areas (e.g., pelvis and knees, abdomen and pelvis), single day imaging, or single area imaging over 2 or more days	78831
Radiopharmaceutical localization of tumor, inflammatory process or distribution of radiopharmaceutical agent(s) (includes vascular flow and blood pool imaging, when performed); tomographic (SPECT) with concurrently acquired CT transmission scan for anatomical review, localization, and determination/detection of pathology, minimum 2 areas (e.g., pelvis and knees, abdomen and pelvis), single day imaging, or single area imaging over 2 or more days	78832
Radiopharmaceutical quantification measurement(s) single area (list separately in addition to code for primary procedure)	78835

General Guidelines (SP-1.0)

SP.GG.0001.0.A
v3.0.2026

- Before advanced diagnostic imaging can be considered, there must be an in-person clinical evaluation as well as a clinical re-evaluation after a trial of failed conservative therapy. The clinical re-evaluation may consist of an in-person evaluation or other meaningful contact with the provider's office such as email, web, telephone communications, or clinical documentation from a provider.
- An in-person clinical evaluation performed after the current episode of symptoms started or changed is required and must include relevant:
  - history
  - physical examination
  - neurological examination documenting **AT LEAST ONE** of the following:
    - motor strength testing
    - sensory examination (e.g., documentation of the specific dermatomal distribution of altered sensation)
    - deep tendon reflex examination
    - nerve root tension signs, when applicable (e.g., straight leg raise test, slump test, femoral nerve tension test)
- For those spinal conditions/disorders for which the Spine Imaging Guidelines require a plain x-ray of the spine prior to consideration of an advanced imaging study, the plain x-ray must be performed after the current episode of symptoms started or changed and results need to be available to the requesting provider of the advanced imaging study (see: **Anatomic Guidelines [SP-2.1]**).
- Clinical re-evaluation is required prior to consideration of advanced diagnostic imaging to document failure of clinical improvement following a six-week trial of provider-directed treatment after the current set of symptoms or physical exam findings started or changed. Clinical re-evaluation can include documentation of an in-person encounter with a provider or documentation of other meaningful contact with a provider's office by the individual (e.g., telephone call, electronic mail, telemedicine, or messaging).
  - Provider-directed treatment may include education, activity modification, NSAIDs (non-steroidal anti-inflammatory drugs), narcotic and non-narcotic analgesic medications, oral or injectable corticosteroids, a provider-directed home exercise/stretching program, cross-training, avoidance of aggravating activities, physical/occupational therapy, spinal manipulation, interventional pain procedures and other pain management techniques.
- Any bowel/bladder abnormalities or emergent or urgent indications should be documented at the time of the initial clinical evaluation and clinical re-evaluation.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Altered sensation to pressure, pain, and temperature should be documented by the specific anatomic distribution (e.g., dermatomal, stocking/glove or mixed distribution).
- Motor deficits (weakness) should be defined by the specific myotomal distribution (e.g., weakness of toe flexion/extension, knee flexion/extension, ankle dorsi/plantar flexion, wrist dorsi/palmar flexion) and gradation of muscle testing should be documented as follows:

Grading of Manual Muscle Testing	
0	No muscle activation
1	Trace muscle activation, such as a twitch, without achieving full range of motion
2	Muscle activation with gravity eliminated, achieving full range of motion
3	Muscle activation against gravity, full range of motion
4	Muscle activation against some resistance, full range of motion
5	Muscle activation against examiner's full resistance, full range of motion

- Pathological reflexes (e.g., Hoffmann's, Babinski, and Chaddock sign) should be reported as positive or negative.
- Asymmetric reflexes and reflex examination should be documented as follows:

Grading of Reflex Testing	
0	No response
1+	A slight but definitely present response
2+	A brisk response
3+	A very brisk response without clonus
4+	A tap elicits a repeating reflex (clonus)

- Advanced diagnostic imaging is often urgently indicated and may be necessary if serious underlying spinal and/or non-spinal disease is suggested by the presence of certain individual factors referred to as "red flags." See: **Red Flag Indications (SP-1.2)**.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

- Spinal specialist evaluation can be helpful in determining the need for advanced diagnostic imaging, especially for individuals following spinal surgery.
- The need for repeat advanced diagnostic imaging should be carefully considered and may not be medically necessary if prior advanced diagnostic imaging has been performed. Requests for simultaneous, similar studies such as spinal MRI and CT need to be documented as required for pre-operative surgical planning. These studies may be helpful in the evaluation of complex failed spinal fusion cases or needed for pre-operative surgical planning when the determination of both soft tissue and bony anatomy is required.
- Serial advanced imaging, whether CT or MRI, for surveillance of healing or recovery from spinal disease is not supported by the currently available scientific evidence-based medicine for the majority of spinal disorders.
  - Requests for repeat imaging may be considered on a case-by-case basis (e.g., concern for delayed union or non-union of spinal fracture, pseudoarthrosis of fusion, etc.).
- Advanced imaging is not considered medically necessary for resolved or improving spinal pain and/or radiculopathy.
- Advanced diagnostic imaging has not been shown to be of value in individuals with stable, longstanding spinal pain without neurological features or without clinically significant or relevant changes in symptoms or physical examination findings.
- Anatomic regions of the spine/pelvis that are included in the following MRI and CT advanced diagnostic imaging studies:
  - Cervical spine: from the skull base/foramen magnum through T1
  - Thoracic spine: from C7 through L1
  - Lumbar spine: from T12 through mid-sacrum
  - Pelvis: includes hips, sacroiliac joints, sacrum, coccyx
- CT or MRI of the cervical and thoracic spine will image the entire spinal cord since the end of the spinal cord or conus medullaris usually ends at L1 in adults. Therefore, lumbar spine imaging is not needed when the goal is to image only the spinal cord unless there is known or suspected low lying conus medullaris (e.g., tethered cord).

Health Equity Consideration

Health equity is the highest level of health for all individuals; health inequity is the avoidable difference in health status or distribution of health resources due to the social conditions in which individuals are born, grow, live, work, and age. Social determinants of health are the conditions in the environment that affect a wide range of health, functioning, and quality of life outcomes and risks. Examples include the following: safe housing, transportation, and neighborhoods; racism, discrimination, and violence; education, job opportunities, and income; access to nutritious foods and physical activity opportunities; access to clean air and water; and language and literacy skills.

General Considerations (SP-1.1)

SP.GG.0001.1.A
v3.0.2026

- See: **General Guidelines (SP-1.0)**

Background and Supporting Information

Straight leg raise test (also known as the Lasegue's test) – With the individual in the supine position, the hip medially rotated and adducted, and the knee extended, the examiner flexes the hip until the individual complains of pain or tightness in the back or back of the leg. If the pain is primarily back pain, it is less specific whereas if the pain is primarily in the leg, it is more likely nerve root irritation/radiculopathy. Disc herniation or pathology causing pressure between the two extremes are more likely to cause pain in both areas. The examiner then slowly and carefully drops the leg back (extends it) slightly until the individual feels no pain or tightness. The individual is then asked to flex the neck so the chin is on the chest, or the examiner may dorsiflex the individual's foot, or both actions may be done simultaneously. Both maneuvers are considered to be provocative tests for neurological tissue.

Slump test – The individual is seated on the edge of the examination table with the legs supported, the hips in neutral position, and the hands behind the back. The examination is performed in sequential steps. First, the individual is asked to "slump" the back into thoracic and lumbar flexion. The examiner maintains the individual's chin in neutral position to prevent neck and head flexion. The examiner then uses one arm to apply overpressure across the shoulders to maintain flexion of the thoracic and lumbar spines. While this position is held, the individual is asked to actively flex the cervical spine and head as far as possible (i.e., chin to chest). The examiner then applies overpressure to maintain flexion of all three parts of the spine (cervical, thoracic, and lumbar) using the hand of the same arm to maintain overpressure in the cervical spine. With the other hand, the examiner then holds the individual's foot in maximum dorsiflexion. While the examiner holds these positions, the individual is asked to actively straighten the knee as much as possible. The test is repeated with the other leg and then with both legs at the same time. If the individual is unable to fully extend the knee because of pain, the examiner releases the overpressure to the cervical spine and the individual actively extends the neck. If the knee extends further, the symptoms decrease with neck extension, or the positioning of the individual increases the individual's symptoms, then the test is considered positive.

Femoral nerve tension test (also known as the prone knee bending test) – The individual lies prone while the examiner passively flexes the knee as far as possible so that the individual's heel rests against the buttock. At the same time, the examiner should ensure that the individual's hip is not rotated. If the examiner is unable to flex the

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

individual's knee past 90 degrees because of a pathological condition in the hip, the test may be performed by passive extension of the hip while the knee is flexed as much as possible. The flexed knee position should be maintained for 45 to 60 seconds. Unilateral neurological pain in the lumbar area, buttock, and/or posterior thigh may indicate an L2 or L3 nerve root lesion. Pain in the anterior thigh indicates tight quadriceps muscles or stretching of the femoral nerve.

Hoffmann's sign – The examiner holds the individual's middle finger and briskly flicks the distal phalanx. A positive test is noted if the interphalangeal joint of the thumb of the same hand flexes.

Babinski's sign – The examiner runs a sharp instrument along the plantar surface of the foot from the calcaneus along the lateral border to the forefoot. A positive test occurs with extension of the great toe with flexion and splaying of the other toes. A negative test occurs with no movement of the toes at all or uniform bunching up of the toes.

Chaddock sign – The examiner strokes the lateral malleolus. A positive test occurs with extension of the great toe.

Red Flag Indications (SP-1.2)

SP.GG.0001.2.A
v3.0.2026

Red Flag Indications are intended to represent the potential for life or limb threatening conditions. Red Flag Indications are clinical situations in which localized spine pain and associated neurological features are likely to reflect serious underlying spinal and/or non-spinal disease and warrant exception to the requirement for documented failure of six weeks of provider-directed treatment. Advanced diagnostic imaging of the symptomatic level is medically necessary **and/or** work-up for a non-spinal source of spine pain for Red Flag Indications.

- Red Flag Indications include:
  - Motor Weakness
  - Aortic Aneurysm or Dissection
  - Cancer
  - Cauda Equina Syndrome
  - Fracture
  - Infection
  - Severe Radicular Pain

Motor Weakness

(See: Grading of Manual Muscle Testing and Reflex Testing in **General Guidelines [SP-1.0]**)

History, Symptoms or Physical Exam Findings (In-person clinical evaluation for the current episode of the condition required)	Advanced Diagnostic Imaging
Clinical presentation including one or more of the following: • New onset motor weakness of grade 3/5 or less of specified muscle(s) • New onset foot drop • New onset bilateral lower extremity weakness • Progressive objective motor/sensory/deep tendon reflex deficits on clinical re-evaluation	MRI of the relevant spinal level* without contrast **OR** MRI of the relevant spinal level* without and with contrast **The SI joint and sacrum are relevant levels of the spine and are captured with pelvic imaging.*

Aortic Aneurysm or Dissection

History, Symptoms or Physical Exam Findings (In-person clinical evaluation for the current episode of the condition required)	Advanced Diagnostic Imaging
• New onset of back and/or abdominal pain in an individual with a known AAA; ***or*** • Acute dissection is suspected.	Spine imaging is not medically necessary, see: **Aortic Disorders, Renal Vascular Disorders and Visceral Artery Aneurysms (PVD-6)** in the Peripheral Vascular Disease Imaging Guidelines

Proprietary Information of UnitedHealthcare.

Cancer

History, Symptoms or Physical Exam Findings (In-person clinical evaluation for the current episode of the condition required)	Advanced Diagnostic Imaging
There is clinical suspicion of spinal malignancy **AND ONE** or more of the following: • Night pain • Uncontrolled or unintended weight loss • Pain unrelieved by change in position • Age >70 years • Severe or worsening spinal pain	**ONE** of the following: • MRI of the relevant spinal level* without contrast **OR** • MRI of the relevant spinal level* without and with contrast **OR** • CT of the relevant spinal level* without contrast **OR** • CT Myelogram of the relevant spinal level* **The SI joint and sacrum are relevant levels of the spine and are captured with pelvic imaging*.
Individual with a known history of cancer with back pain raising suspicion of spinal malignancy	See: **Spinal/Vertebral Metastases (ONC-31.6)** in the Oncology Imaging Guidelines

Cauda Equina Syndrome

History, Symptoms or Physical Exam Findings (In-person clinical evaluation for the current episode of the condition required)	Advanced Diagnostic Imaging
Clinical presentation including one or more of the following: • Acute onset of bilateral sciatica • Perineal sensory loss (“saddle anesthesia”) • Decreased anal sphincter tone • New onset bowel/bladder incontinence • Otherwise unexplained acute urinary retention	MRI Lumbar Spine without contrast (CPT® 72148) **OR** MRI Lumbar Spine without and with contrast (CPT® 72158)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Fracture

History, Symptoms or Physical Exam Findings (In-person clinical evaluation for the current episode of the condition required)	Advanced Diagnostic Imaging
• Clinical suspicion of a pathological spinal fracture. ◦ Advanced imaging is medically necessary after x-ray; no conservative treatment is needed.	See: **Spinal Compression Fractures (SP-11.1)** for appropriate imaging studies
• Clinical suspicion of a spinal fracture after trauma ◦ Advanced imaging is medically necessary after x-ray; no conservative treatment is needed.	See: **Neck (Cervical Spine) Trauma (SP-3.2)**, **Upper Back (Thoracic Spine) Trauma (SP-4.2)**, or **Low Back (Lumbar Spine) Trauma (SP-6.2)** for appropriate imaging studies
• Clinical suspicion of a spinal fracture related to ankylosing spondylitis or diffuse idiopathic skeletal hyperostosis (DISH) ◦ Advanced imaging is medically necessary ***without*** x-ray or conservative treatment.	See: **Neck (Cervical Spine) Trauma (SP-3.2)**, **Upper Back (Thoracic Spine) Trauma (SP-4.2)**, **Low Back (Lumbar Spine) Trauma (SP-6.2)**, or **Inflammatory Spondylitis (SP-10.2)** for appropriate imaging studies

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Infection

History, Symptoms or Physical Exam Findings (In-person clinical evaluation for the current episode of the condition required)	Advanced Diagnostic Imaging
There is a clinical suspicion of spinal infection (e.g., disc space infection, epidural abscess, or spinal osteomyelitis) and one or more of the following: • Fever • History of IV drug use • Recent bacterial infection (UTIs, pyelonephritis, pneumonia) • Recent spinal intervention (e.g., surgery, pain injection, or stimulator implantation) • Immunocompromised states • Long term use of systemic glucocorticoids • Organ transplant recipient taking anti-rejection medication • Diabetes mellitus • HIV/AIDS • Chronic dialysis • Immunosuppressant therapy • Neoplastic involvement of the spine • Laboratory values indicative of infection (e.g., elevated WBC, ESR, CRP, positive cultures) • Decubitus ulcer or wound overlying spine • Abnormal x-ray or CT suspicious for infection	**ONE** of the following: • MRI of the relevant spinal level* without and with contrast **OR** • MRI of the relevant spinal level* without contrast **OR** • CT of the relevant spinal level* without IV contrast **OR** • CT of the relevant spinal level* with IV contrast **OR** • FDG-PET/CT whole-body when x-ray or CT are abnormal **AND** when MRI cannot be performed or is inconclusive **OR** • 3-phase bone scan complete spine **OR** • Bone SPECT or Bone SPECT/CT **OR** • Gallium scan whole body or limited spine **OR** • Gallium SPECT or SPECT/CT **OR** • Gallium scan whole body or limited spine** with SPECT or SPECT/CT **The SI joint and sacrum are relevant levels of the spine and are captured with pelvic imaging.* ***Any bone scan can be combined with any Gallium scan*

Click Here to Return to the Main TOC

Definitions (SP-1.3)

SP.GG.0001.3.A
v3.0.2026

- **Radiculopathy**, for the purpose of this policy, is defined as the presence of pain resulting in significant functional limitations (i.e., diminished quality of life and impaired, age-appropriate activities of daily living), dysaesthesia(s) or paraesthesia(s) reported by the individual in a specified dermatomal distribution of an involved named spinal root(s) and **ONE or MORE** of the following:
  - Loss of strength of specific named muscle(s) or myotomal distribution(s) or demonstrated on detailed neurologic examination (within the prior 3 months), concordant with nerve root compression of the involved named spinal nerve root(s).
  - Altered sensation to light touch, pressure, pin prick or temperature demonstrated on a detailed neurologic examination (within the prior 3 months) in the sensory distribution concordant with nerve root compression of the involved named spinal nerve root(s).
  - Diminished, absent, or asymmetric reflex(es) on a detailed neurologic examination (within the prior 3 months) concordant with nerve root compression of the involved named spinal nerve root(s).
  - **Either** of the following:
    - A concordant radiologist's interpretation of an advanced diagnostic imaging study (MRI or CT) of the spine demonstrating compression of the involved named spinal nerve root(s) or foraminal stenosis at the concordant level(s) (performed within the prior 12 months).
    - Electrodiagnostic studies (EMG/NCV's) diagnostic of nerve root compression of the involved named spinal nerve root(s) (performed within the prior 12 months).
- **Radicular pain** is pain which radiates to the upper or lower extremity along the course of a spinal nerve root, typically resulting from compression, inflammation and/or injury to the nerve root.
- **Radiculitis** is defined, for the purpose of this policy, as radicular pain without objective neurological findings.

Evidence Discussion (SP-1)

v3.0.2026

Prior to advanced imaging, it is critical to perform a detailed history and physical examination in the evaluation of an individual for spinal pathology.[22,23,24] Features of the clinical history and physical examination not only help in the formulation of a differential diagnosis but also influence decisions about diagnostic imaging.[3] Also, as the more common findings on imaging studies are often nonspecific and non-diagnostic, clinical history and exam findings play a crucial role.[32] These incidental findings may lead to unnecessary further diagnostic workup and additional negative downstream outcomes.

Multiple studies have shown most individuals with acute neck or back pain will improve with 6 weeks of conservative care;[9,25,26] however, conservative care would not be necessary for individuals with Red Flag Indications.[15]

Risks associated with imaging include but are not limited to radiation exposure and contrast complications.[27,29] Studies have also linked the increase rate of imaging with the increase rate of surgery and also found early magnetic resonance imaging (MRI) had an eight-fold increased risk of surgery.[27,28] It should also be of note that routine repeat advanced imaging for many spinal conditions has been shown to have limited value.[4,30,31]

Anatomic Guidelines (SP-2.1)

SP.IM.0002.1.A
v3.0.2026

- Anatomic regions of the spine/pelvis that are included in the following MRI and CT advanced diagnostic imaging studies:
  - Cervical spine: from the skull base/foramen magnum through T1
  - Thoracic spine: from C7 through L1
  - Lumbar spine: from T12 through mid-sacrum
  - Pelvis: includes hips, sacroiliac joints, sacrum, coccyx
- CT or MRI cervical and thoracic spine will image the entire spinal cord since the end of the spinal cord or conus medullaris usually ends at L1 in adults. Therefore, lumbar spine imaging is not needed when the goal is to image only the spinal cord unless there is known or suspected low-lying conus medullaris (e.g., tethered cord).
- The results of plain x-rays performed after the current episode of symptoms started or changed need to be available to the requesting provider of the advanced imaging study for the following conditions:
  - See: **Spinal Compression Fractures (SP-11)**
  - See: **Lumbar Spine Spondylolysis/Spondylolisthesis (SP-8)**
  - See: **Inflammatory Spondylitis (SP-10.2)**
  - See: **Upper Back (Thoracic Spine) Pain without and with Neurological Features (Including Stenosis) (SP-4.1)**
  - See: **Neck (Cervical Spine) Trauma (SP-3.2)**
  - See: **Coccydynia without Neurological Features (SP-5.2)**
  - See: **Spinal Deformities (e.g., Scoliosis/Kyphosis) (SP-14)** and **Spinal Dysraphism (PEDSP-4)** in the Pediatric and Special Populations Spine Imaging Guidelines
  - See: **Sacro-Iliac (SI) Joint Pain, Inflammatory Spondylitis/Sacroiliitis and Fibromyalgia (SP-10)**
  - See: **Post-Operative Spinal Disorders (SP-15)**

MRI of the Spine (SP-2.2)

SP.IM.0002.2.A
v3.0.2026

- See: **Procedure Codes Associated with Spine Imaging**
- For MR Spectroscopy, all spine uses are considered not medically necessary.
  - See: **Imaging of Intervertebral Discs (SP-2.5)**
- MRI Spine is performed either without contrast, with contrast *or* without and with contrast. A "with contrast" study alone is medically necessary only to complete a study begun without contrast. Contrast is generally not medically necessary for most disc and nerve root disorders, fractures, and degenerative disease.
- MRI Spine indications include:
  - Evaluation of disc disease, spinal cord and nerve root disorders and most other spinal conditions including evaluation of congenital anomalies of the spine and spinal cord
  - Suspicion for or surveillance of known spine/spinal canal/spinal cord neoplastic disease
  - Suspicion, diagnosis of or surveillance of spinal infections, multiple sclerosis, or other causes of myelitis, syringomyelia, cauda equina syndrome or other "red flag" indications. See: **Red Flag Indications (SP-1.2)**.
  - Pre-operative evaluation to define abnormal or variant spinal anatomy that could influence the outcome of a potential surgical procedure. See: **Prior to Spine Surgery (SP-16.1)**
  - Spinal imaging for individuals having undergone recent spinal surgery (e.g., laminectomy, discectomy, spinal decompression), when history and physical examination is suspicious for hematoma, post-surgical infection, or cerebrospinal fluid (CSF) leak

Positional MRI

- Positional MRI is also referred to as dynamic, weight-bearing or kinetic MRI. Currently, there is inadequate scientific evidence to support the medical necessity of this study. As such, it should be considered not medically necessary.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

CT of the Spine (SP-2.3)

SP.IM.0002.3.A
v3.0.2026

- See: **Procedure Codes Associated with Spine Imaging**
- CT Spine indications include:
  - Contraindication to MRI
    - CT (contrast as requested) is medically necessary when **ANY** of the following MRI contraindications are documented:
      - Implanted ferromagnetic materials
      - Electronically, magnetically, or mechanically activated implanted devices that are not determined by the manufacturer as MRI compatible/conditional
  - CT without contrast, or CT without and with contrast (even if MRI has already been performed), for any spinal trauma/fractures, especially spinal trauma/fractures that could result in spinal instability and spinal cord/spinal nerve compression
  - CT without contrast, or CT without and with contrast (even if MRI has already been performed), for spinal neoplastic disease – primary or metastatic
  - CT without contrast, or CT without and with contrast (even if MRI has already been performed), in conjunction with myelography or discography (see: **CT/ Myelography [SP-2.4]** and **Imaging of Intervertebral Discs [SP-2.5]**)
  - CT without contrast, or CT without and with contrast (even if MRI has already been performed), for pre-operative evaluation to define abnormal or variant bony spinal anatomy that could influence the outcome of a potential surgical procedure (see: **Prior to Spine Surgery [SP-16.1]**)
  - CT without contrast, or CT without and with contrast, (even if MRI has already been performed), to assess spinal fusions when pseudoarthrosis is suspected (not to be used for routine post-operative assessment where x-rays are sufficient and/or there are no concordant clinical signs or symptoms)
  - CT without contrast, or CT without and with contrast (even if MRI has already been performed), for congenital, developmental, or acquired spinal deformity (see: **Spinal Deformities [e.g., Scoliosis/Kyphosis] [SP-14]**)
  - CT without contrast, or CT without and with contrast, for spondylolysis when routine x-rays are negative and/or MRI is equivocal, indeterminate, or non-diagnostic (see: **Lumbar Spine Spondylolysis/Spondylolisthesis [SP-8]**)
  - CT without contrast, or CT without and with contrast, to evaluate calcified lesions, (e.g., osteophytes, ossification of the posterior longitudinal ligament [OPLL])

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

CT/Myelography (SP-2.4)

SP.IM.0002.4.A
v3.0.2026

- See: **Procedure Codes Associated with Spine Imaging**
- CT/Myelography is generally unnecessary as an initial study when a diagnostic quality MRI has been obtained.
- CT/Myelography indications include:
  - To clarify equivocal, indeterminate, or non-diagnostic MRI findings or to further evaluate the significance of multiple spinal abnormalities
  - When an MRI is contraindicated (see: **CT of the Spine [SP-2.3]**)
  - Pre-operative planning for spine surgery, (e.g., multilevel spinal stenosis or when a previous MRI is insufficient, equivocal, indeterminate, or non-diagnostic) (see: **Prior to Spine Surgery (SP-16.1)**)
  - Evaluation after previous spinal surgery when an MRI without and with contrast is contraindicated or MRI results are equivocal, indeterminate, or non-diagnostic
  - The guidelines allow for the approval of the post-myelogram CT (i.e., CPT® 72126, CPT® 72129, and CPT® 72132) only and not any other myelogram-related procedure codes (i.e., CPT® 72265 or CPT® 62284).

Click Here to Return to the Main TOC

Imaging of Intervertebral Discs (SP-2.5)

SP.IM.0002.5.A
v3.0.2026

Post-lumbar Discography CT

- The guidelines allow for the post-lumbar discography CT procedure codes only and do not include any other discography-related procedure codes. A post-lumbar discography CT is considered medically necessary following an approved discography and **ALL** the following apply:
  - A post-discography CT is coded as without contrast.
  - A CT Lumbar Spine without contrast (CPT® 72131) is medically necessary if verified to be performed as a post-discography CT.
  - When a post-discography CT is requested and the discography has already been approved, authorization will be issued for the post-discography CT procedure codes.

Magnetic Resonance Spectroscopy

- Magnetic Resonance Spectroscopy (MRS) involves the analysis of the levels of certain chemicals in pre-selected voxels (small regions) on an MRI scan done at the same time.
  - MRS (CPT® 76390, 0609T, 0610T, 0611T, and 0612T) is considered not medically necessary for all spine imaging uses at this time.

Background and Supporting Information

- Provocative Discography/CT and MR Spectroscopy lumbar spine are procedures purported to diagnose (or rule-out) a discogenic “pain generator” (i.e., the source of non-specific axial spinal pain). These diagnostic studies, when reported as positive, are often used as an indication for spinal fusion in individuals with non-specific axial back pain.
- The following uses of discography are considered controversial:
  - To identify a symptomatic pseudoarthrosis in a failed spinal fusion
  - To identify which of two herniated discs seen on MRI is symptomatic when not determined clinically or otherwise
  - To confirm the discogenic nature of pain in an individual with an abnormal disc seen on MRI and to rule out pain from an adjacent disc level
  - To confirm the presumptive diagnosis of “internal disc disruption”
  - Discography of the cervical and/or thoracic spine
- The following uses of MR Spectroscopy lumbar spine are considered controversial:

Ultrasound of the Spinal Canal (SP-2.6)

SP.IM.0002.6.A
v3.0.2026

- Spinal canal ultrasound (CPT® 76800) describes the evaluation of the spinal cord (canal and contents), most often performed in newborns, infants, young children and intraoperatively.
- CPT® 76800 describes evaluation of the entire spine and should not be reported multiple times for imaging of different areas of the spinal canal.
- CPT® 76998, rather than CPT® 76800, should be used to report intraoperative spinal canal ultrasound (ultrasonic guidance). Intraoperative use of spinal ultrasound (CPT® 76998) would not require prior authorization.

Indications for spinal canal ultrasound (CPT® 76800):

- This study is generally limited to infants, newborns, and young children because of incomplete ossification of the vertebral segments surrounding the spinal cord, including the assessment of CSF in the spinal canal and for image-guided lumbar puncture.
- When ossification of the vertebral segments is incomplete for evaluation of suspected or known tethered cord (see: **Tethered Cord [PEDSP-5]** in the Pediatric and Special Populations Spine Imaging Guidelines).
- Evaluation of suspected occult and non-occult spinal dysraphism (see: **Spinal Dysraphism [PEDSP-4]** in the Pediatric and Special Populations Spine Imaging Guidelines).
- Evaluation of spinal cord tumors, vascular malformations, and cases of birth-related trauma.
- Contraindicated for use in the adult spine for the assessment of spinal pain, radiculopathy, facet inflammation, nerve root inflammation, disc herniation, and soft tissue conditions surrounding the adult spine other than for superficial masses.

Proprietary Information of UnitedHealthcare.

Click Here to Return to the Main TOC

Limitations of Spinal Imaging in Degenerative Disorders (SP-2.7)

SP.IM.0002.7.A

v3.0.2026

- Non-specific axial spinal pain is ubiquitous. Advanced diagnostic imaging infrequently identifies the source of the spinal pain (pain generator).
- Incidental findings on MRI and CT, including bulging, protruding, extruding or herniated discs, are often non-concordant, asymptomatic and increase in incidence as the spine ages.
- In individuals with poorly defined clinical presentations, “abnormal” spinal advanced diagnostic imaging results are infrequently clinically concordant, significant, material or substantive and may even lead to inappropriate treatment.
- Performing advanced spinal imaging based only on the presence of spinal degenerative findings identified on x-rays is not generally medically necessary in individuals who are either asymptomatic or present with non-specific axial spinal pain.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Miscellaneous Spinal Lesions (SP-2.8)

SP.IM.0002.8.A
v3.0.2026

Vertebral body hemangiomas

- Vertebral body hemangiomas are common and are generally benign and incidental findings on plain x-rays and advanced diagnostic imaging studies.
- If the appearance of a vertebral body hemangioma is typical on plain x-ray, further spinal advanced diagnostic imaging is not usually required, unless there are associated neurologic symptoms or signs on physical examination.
- If the appearance of a vertebral body hemangioma is atypical on plain x-ray, with or without neurological signs or symptoms on physical exam, MRI without contrast or MRI without and with contrast is medically necessary.
- Occasionally, MRI may be equivocal, indeterminate, or non-diagnostic and CT without contrast of the spinal area is medically necessary to help clarify the diagnosis.
- No follow-up imaging is necessary once the diagnosis of a vertebral body hemangioma is established without neurological features.

Tarlov cysts

- Tarlov cysts are most often cystic dilatations of nerve root sleeves in the lumbar spine and sacrum.
- Controversy exists as to whether Tarlov cysts can result in neurologic signs and symptoms but they can result in erosion of the adjacent bone.
- Usually Tarlov cysts are benign, incidental findings on advanced diagnostic imaging studies. Further evaluation of a known or suspected Tarlov cyst can be performed with an MRI Lumbar Spine without and with contrast study (CPT® 72158) or CT/ Myelography Lumbar Spine (CPT® 72132).

Other spinal lesions

- MRI without and with contrast or a CT without contrast is medically necessary if:
  - Other spinal lesions are seen on routine x-rays or a non-contrast MRI; ***and***
  - These additional advanced imaging studies are recommended by a spine specialist or radiologist to further characterize or diagnose the lesion; ***or***
  - Required for surgical planning.

MRA Spinal Canal (SP-2.9)

SP.IM.0002.9.A
v3.0.2026

- MR angiography (MRA) Spine (CPT® 72159) imaging is utilized infrequently.
- Cerebrospinal Fluid (CSF) flow studies using MRI are included in CPT® codes 70551, 70552, and 70553 and should not be coded or reported separately, (see **CSF Flow Imaging (HD-24.4)**)

Indications may include:

- Suspected spinal cord arteriovenous malformation (AVM) or arteriovenous fistula (AVF):
  - MRI Spine of the relevant spine region without and with contrast should be the initial imaging study.
  - If suspicion for a spinal AVM or AVF is high based upon the results of the MRI Spine, catheter angiography is recommended.
- Subarachnoid hemorrhage where no brain aneurysm has been previously identified
  - Catheter angiography should be performed and is the most definitive study to define possible spinal pathology resulting in a spinal canal subarachnoid hemorrhage.
  - See: **General Guidelines – CT and MR Angiography (CTV and MRV) (HD-1.5)** in the Head Imaging Guidelines
  - See: **Cerebral Aneurysms (HD-12.1)** in the Head Imaging Guidelines
- Pre-operative planning
  - MRA Spinal canal may be useful in identifying major intercostal feeder vessels to the spinal cord prior to surgical procedures that might interfere with this blood supply. However, catheter angiography is generally a more definitive study for this purpose.
- 3D Rendering (CPT® 76377 or CPT® 76376) is medically necessary with spinal angiography to define the presence, location, and anatomy of intraspinal vascular malformations.

Spine PET/CT (SP-2.10)

SP.IM.0002.10.A

v3.0.2026

- At the present time there is controversy regarding spine PET/CT due to inadequate scientific evidence to support the medical necessity of PET/CT for the routine assessment of spinal disorders, other than for neoplastic disease.
- See: **Spinal/Vertebral Metastases (ONC-31.6)** in the Oncology Imaging Guidelines
- Spine PET/CT should be considered not medically necessary.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Cone-beam CT (SP-2.11)

SP.IM.0002.11.A

v3.0.2026

- Cone-beam CT for imaging of the cervical spine is considered not medically necessary.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Evidence Discussion (SP-2)

v3.0.2026

- X-rays are first line imaging for suspected inflammatory spine disease[6], following trauma[13], concerns of spinal deformities[7], or post-operative spinal disorders[8]. Although x-rays may not confirm a definitive diagnosis, they provide information that can better direct advanced imaging modalities.
- MRI utilizes a magnetic field and radio waves with computer processing to produce detailed images which have excellent soft tissue characterization and is the primary modality for evaluating the spinal cord, intervertebral disc disease and other soft tissue pathology of the spine.[9,10,11] Positional MRI[2] and MR Spectroscopy[20] lacks sufficient scientific evidence to support its routine clinical use.[2]
- CT is medically necessary as an alternative to MRI when MRI is contraindicated or equivocal.[10,12,13,15] CT is also medically necessary for evaluation of bony pathology including but not limited to fractures[13], bony neoplastic disease[15], calcified lesions[16], post traumatic[13] and perioperative bony processes.[8,14] Following lumbar discography CT is medically necessary to evaluate disc anatomy.[19]
- CT/Myelography provides indirect visualization of the thecal sack in the spinal canal. MRI is the primary medically necessary advanced imaging for these indications as the cord, thecal sac, and spinal canal can be directly visualized. CT/Myelography may be medically necessary when MRI is indeterminate or contraindicated.[17,18]
- Ultrasound can be used to visualize the spinal canal in young children before the posterior elements ossify. Ultrasound will not penetrate ossified bone.[21]
- MRA has limited indications in spine imaging but may be appropriate for evaluating spinal vascular malformations.
- There is inadequate scientific evidence to support the medical necessity of PET/CT for the routine assessment of spinal disorders, other than for neoplastic disease.
- There is inadequate scientific evidence to support the medical necessity of cone beam CT for the routine assessment of spinal disorders outside of the operative setting which is outside the coverage of these guidelines.

Neck (Cervical Spine) Pain without and with Neurological Features (Including Stenosis) (SP-3.1)

SP.NP.0003.1.A
v3.0.2026

***All* the following are required prior to advanced imaging:**
• An in-person clinical evaluation for the current episode of the condition is required to have been performed before advanced imaging is considered. This may have been either the initial clinical evaluation or a clinical re-evaluation (see also: **General Guidelines (SP-1.0)**). • Failure of a 6-week trial of provider-directed treatment after the current set of symptoms or physical exam findings started or changed (unless presence of a red flag as defined in **Red Flag Indications (SP-1.2)**) • Clinical re-evaluation after treatment period (may consist of an in-person evaluation or other meaningful contact (see also: **General Guidelines (SP-1.0)**)

Advanced Diagnostic Imaging:	MRI Cervical Spine, without contrast (CPT® 72141)
Comments:	CT Cervical Spine without contrast (CPT® 72125) **OR** CT Myelography (CPT® 72126) is medically necessary when MRI is contraindicated.

Neck (Cervical Spine) Trauma (SP-3.2)

SP.NP.0003.2.A
v3.0.2026

***All* the following are required prior to advanced imaging:**
• An in-person clinical evaluation for the current episode of the condition is required to have been performed before advanced imaging is considered. This may have been either the initial clinical evaluation or a clinical re-evaluation (see also: **General Guidelines (SP-1.0)**). • Failure of a 6-week trial of provider-directed treatment after the current set of symptoms or physical exam findings started or changed (unless presence of a red flag as defined in **Red Flag Indications (SP-1.2)**) • Clinical re-evaluation after treatment period (may consist of an in-person evaluation or other meaningful contact (see also: **General Guidelines (SP-1.0)**) • Results of plain x-rays of the cervical spine performed after the current episode of symptoms started or changed need to be available to the requesting provider (not required for high-risk mechanisms as below**)

Advanced Diagnostic Imaging:	**MRI Cervical Spine without contrast (CPT® 72141) OR CT Cervical Spine without contrast (CPT® 72125)** **For individuals with ankylosing spondylitis or DISH (diffuse idiopathic skeletal hyperostosis), both MRI of the entire spine (CPT® 72141, 72146, and/or 72148) AND CT of the entire spine (CPT® 72125, 72128, and/or 72131) are medically necessary** **For individuals with ankylosing spondylitis or DISH, plain x-rays and a 6-week trial of provider-directed treatment and clinical re-evaluation are NOT required.**
Comments:	Plain x-rays **ARE** required for suspected fracture in **non-high** risk injuries. Plain x-rays and a 6-week trial of provider-directed treatment and clinical re-evaluation are **NOT** required for individuals with a high risk factor(s) for suspected cervical spine injury within the last 3 months (See below**).

**High-risk factors of suspected cervical spine injury may include:

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Long term use of systemic glucocorticoids
- History of prior low energy fractures
- History of low bone mineral density
- Age ≥65 years
- Head trauma and/or maxillofacial trauma
- Pedestrian in a motor vehicle accident
- Fall from elevation ≥3 feet/5 stairs
- Diving accident
- Head-on motor vehicle collision without/with airbag deployment
- Rollover motor vehicle collision
- Ejection from the vehicle in a motor vehicle collision
- High speed of the vehicle at the time of collision
- Not wearing a seatbelt/shoulder harness in a motor vehicle collision
- Minor direct/indirect trauma to the cervical spine/maxillofacial areas in individuals with ankylosing spondylitis or DISH

Background and Supporting Information

- Pain radiation patterns from the cervical spine area into the thoracic spine area do not necessarily justify the addition of thoracic spine advanced diagnostic imaging.
- Cervical radiculopathy is often confused with shoulder disorders, brachial plexopathy, peripheral nerve entrapment and/or motor/sensory neuropathies. Electrodiagnostic testing (EMGs/NCVs) is generally used to confirm, not establish, a diagnosis of peripheral nerve entrapment and/or a motor/sensory neuropathy based upon history and physical examination findings. Electrodiagnostic testing is often considered when advanced imaging of the spine does not reveal neurocompressive pathology and/or after 6 weeks of unimproved symptoms of extremity pain, weakness, numbness and/or tingling.
- Individuals with ankylosing spondylitis or DISH are at high risk of cervical spine fractures even with minor direct/indirect trauma to the cervical spine which can result in quadriparesis/quadriplegia.

Evidence Discussion (SP-3)

v3.0.2026

X-rays provide critical information that cannot be obtained with advanced imaging modalities and remain central to providing optimal care for spine individuals.[8,15,17] Unnecessary CT scans increase individuals' radiation exposure,[18] however, is the initial imaging for individuals involved in trauma with a high-risk factor for cervical spine injury.[7] Additionally, for individuals with diffuse idiopathic skeletal hyperostosis (DISH) or ankylosing spondylitis with a history of low-energy trauma, whole spine MRI or CT imaging is mandatory due to the high prevalence of acute fractures and the low specificity for fracture detection on radiographs.[10,12] The American College of Radiology (ACR) Appropriateness Criteria for Cervical Neck Pain or Cervical Radiculopathy (revised 2018) indicates that in the absence of red flag symptoms, early advanced imaging may not be required as abnormal findings are not uncommon in asymptomatic individuals and correlate poorly with the presence of neck pain.[8]

Upper Back (Thoracic Spine) Trauma (SP-4.2)

SP.TS.0004.2.A
v3.0.2026

All the following are required prior to advanced imaging:
• An in-person clinical evaluation for the current episode of the condition is required to have been performed before advanced imaging is considered. This may have been either the initial clinical evaluation or a clinical re-evaluation (see also: **General Guidelines (SP-1.0)**). • Failure of a 6-week trial of provider-directed treatment after the current set of symptoms or physical exam findings started or changed (unless presence of a red flag as defined in **Red Flag Indications (SP-1.2)**). • Clinical re-evaluation after treatment period (may consist of an in-person evaluation or other meaningful contact (see also: **General Guidelines (SP-1.0)**). • Conservative treatment and clinical re-evaluation are not required in high-risk individuals. ◦ High-risk individuals include those that have sustained an acute traumatic injury with midline thoracolumbar tenderness, high-energy injury mechanisms, or >60 years of age. • **After above criteria are met:** MRI Thoracic Spine without contrast (CPT® 72146) OR CT Thoracic Spine without contrast (CPT® 72128)

Indication:	Advanced Imaging
Ankylosing Spondylitis (AS) or Diffuse Idiopathic Skeletal Hyperostosis (DISH)	• MRI of the entire spine (CPT® 72141, 72146, and/or 72148) **AND** • CT of the entire spine (CPT® 72125, 72128, and/or 72131) For individuals with AS or DISH, a 6-week trial of provider-directed treatment and clinical re-evaluation are **NOT** required

Background and Supporting Information

- Thoracic radiculopathy presents with pain radiation from the thoracic spine around the trunk. At upper thoracic spine levels, the pain radiation is from the thoracic spine around the rib cage following the sensory distribution of an intercostal nerve.

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

- Advanced diagnostic imaging is generally not medically necessary in evaluation of axial low back pain with radiation toward the thoracic region unless there are documented clinical features indicating a thoracic spine disorder.

Evidence Discussion (SP-4)

v3.0.2026

The precision in identifying thoracic spine diseases is dependent on a meticulous association with the individual's clinical examination and medical history because the usual observations from imaging studies are frequently ambiguous and non-conclusive.[5]

Wood et al. demonstrated that asymptomatic individuals may exhibit positive findings on thoracic spine MRI at a rate as high as 70%.[6] For individuals with atraumatic thoracic back pain, data from Linna, et al. support initial conservative management followed by evaluation by a surgical specialist before ordering a thoracic spine MRI.[5] Red flag indications, however, obviate the need for conservative care.

Regarding the value of x-rays, Goodwin et al. stated that plain films provide critical information that cannot be obtained with other imaging modalities, and they remain central to providing optimal care for spine individuals.[7] When there is a history of blunt trauma and a high-risk factor for thoracic spine injury, however, CT imaging is appropriate for initial imaging.[8,2]

Additionally, for individuals with diffuse idiopathic skeletal hyperostosis (DISH) or ankylosing spondylitis with a history of low-energy trauma, whole spine MRI or CT imaging is considered medically necessary due to the high prevalence of acute fractures and the low specificity for fracture detection on radiographs.[3,4]

Evidence Discussion (SP-5)

v3.0.2026

Acute low back pain is usually a self-limited condition and improves with conservative treatment in 6 weeks. The American College of Radiology (ACR) Appropriateness Criteria for low back pain (revised 2021) states that imaging may be considered in those individuals who have had up to 6 weeks of medical management and physical therapy that resulted in little or no improvement in their back pain.[29]

A meta-analysis by Chou et al. found no clinically significant difference in individual outcomes between those who had immediate lumbar imaging versus usual care.[33] It should also be noted that there are risks associated with imaging including but not limited to radiation exposure and contrast complications.[34] Studies have also linked the increase rate of imaging with the increase rate of surgery and also found early magnetic resonance imaging (MRI) had an eight-fold increased risk of surgery.[34,35]

Health Equity Consideration - Low Back Pain

Low back pain (LBP) is defined by the World Health Organization as the pain between the lower edge of the ribs and the buttocks and is considered acute if it happens suddenly or chronic if it lasts more than 3 months (WHO). In the Global Burden of Diseases, Injuries, and Risk Factors study (2017), over the 28-year period studied, LBP was one of the three leading chronic non-communicable diseases (GBD 2017). There has been exploration of a biopsychosocial paradigm of pain for chronic LBP, which considers influences including psychological, social and environmental factors (Aroke et al. 2020).

Social factors were associated with higher rates of often avoidable/unnecessary utilization outcomes such as Emergency Department visits and hospitalizations, imaging, and associated with lower preventive utilization outcomes, such as PT visits (Pak et al. 2024). In a study (Pak, 2024) social risk factors such as food insecurity and housing instability have shown to have detrimental effects on health, health care outcomes and heath disparities. Income, geographic location, and educational level were identified as contributing to LBP treatment disparities, with increased risk of receiving non-guideline concordant care, including opioid and MRI prescriptions, before conservative treatments were prescribed (Mathieu et al. 2024). Better understanding is needed to address the needs and expectations of patients suffering from LBP and how their individual characteristics may affect their access and utilization of healthcare services.

Lower Extremity Pain with Neurological Features (Radiculopathy, Radiculitis, or Plexopathy and Neuropathy) with or without Low Back (Lumbar Spine) Pain (SP-6.1)

SP.LE.0006.1.A
v3.0.2026

***All* the following are required prior to advanced imaging:**
• An in-person clinical evaluation for the current episode of the condition is required to have been performed before advanced imaging is considered. This may have been either the initial clinical evaluation or a clinical re-evaluation (see also: **General Guidelines (SP-1.0)**). • Failure of a 6 week trial of provider-directed treatment after the current set of symptoms or physical exam findings started or changed (unless presence of a red flag as defined in **Red Flag Indications (SP-1.2)**). • Clinical re-evaluation after treatment period (may consist of an in-person evaluation or other meaningful contact (see also: **General Guidelines (SP-1.0)**).

Advanced Diagnostic Imaging:	**MRI Lumbar Spine without contrast (CPT® 72148)**
Comments:	A CT Lumbar spine without contrast (CPT® 72131) **OR** CT Myelography (CPT® 72132) is medically necessary when MRI is contraindicated. See also: **Lumbar Spinal Stenosis (SP-9.1)**

Evidence Discussion (SP-6)

v3.0.2026

Acute low back pain is usually a self-limited condition and improves with conservative treatment in 6 weeks. The American College of Radiology (ACR) Appropriateness Criteria® for low back pain (revised 2021) states that imaging may be considered in those individuals who have had up to 6 weeks of medical management and physical therapy that resulted in little or no improvement in their back pain.[26]

A meta-analysis by Chou et al. found no clinically significant difference in individual outcomes between those who had immediate lumbar imaging versus usual care.[31] It should also be noted that there are risks associated with imaging including but not limited to radiation exposure and contrast complications.[32] Studies have also linked the increase rate of imaging with the increase rate of surgery and also found early magnetic resonance imaging (MRI) had an eight-fold increased risk of surgery.[32,33] In typical individuals with low back pain or radiculopathy, MR imaging does not appear to have measurable value in terms of planning conservative care, that knowledge of imaging findings does not alter outcome, and that individual knowledge of imaging findings is associated with a lesser sense of well-being.[23]

Myelopathy (SP-7.1)

SP.MI.0007.1.A
v3.0.2026

- Myelopathy is the development of abnormal spinal cord function with long tract signs usually secondary to spinal cord compression, but also inflammation (transverse myelitis, MS, etc.), neoplastic disease or spinal cord infarction.
  - For imaging of transverse myelitis, see: **Transverse Myelitis (HD-16.4)** in the Head Imaging Guidelines.
- Examination findings may include loss of manual dexterity, spastic legs, ataxia, hyperreflexia, upgoing toes (positive Babinski), Hoffmann's sign, sustained clonus, Lhermitte's sign, crossed radial reflex, inverted radial reflex, and/or finger escape sign. Sensory level and urinary incontinence/retention may be seen.
  - Advanced imaging is generally medically necessary in the initial evaluation of documented or reasonably suspected myelopathy.
- X-rays are not required for advanced imaging in individuals with potential myelopathy regardless of any history of spine surgery, trauma, or other reasons which may otherwise require x-rays (e.g., **Neck (Cervical Spine) Trauma (SP-3.2)**, **Upper Back (Thoracic Spine) Trauma (SP-4.2)**, **Post-Operative Spinal Disorders (SP-15)**).
- Conservative treatment is not a requirement for advanced imaging in individuals with potential myelopathy.
- MRI Cervical and Thoracic Spine without contrast, or without and with contrast, are medically necessary for:
  - Evaluation of reasonably suspected myelopathy
  - Post-traumatic syrinx with increased spinal pain or worsening neurological symptoms
  - Sustained, prominent, and unexplained Lhermitte's sign
  - Unexplained Babinski's or Hoffmann's signs
  - Unexplained hyperreflexia
  - Unexplained bilateral motor weakness
- MRI Cervical, Thoracic, and Lumbar Spine without contrast, or without and with contrast, are medically necessary for:
  - Suspected tethered cord and/or low-lying conus medullaris.
- CT without contrast, or CT with contrast (myelography), can also be considered for either of the following:
  - An alternative to MRI, when MRI is contraindicated
  - In addition to MRI, for surgical planning

Background and Supporting Information

Lhermitte's sign – With the individual in the long leg sitting position on the examination table, the examiner passively flexes the individual's head and one hip simultaneously with the leg kept straight. A positive test occurs if there is sharp pain down the spine and into the upper or lower extremities.

Babinski's sign – The examiner runs a sharp instrument along the plantar surface of the foot from the calcaneus along the lateral border to the forefoot. A positive test occurs with extension of the great toe with flexion and splaying of the other toes. A negative test occurs with no movement of the toes at all or uniform bunching up of the toes.

Hoffman's sign – The examiner holds the individual's middle finger and briskly flicks the distal phalanx. A positive test is noted if the interphalangeal joint of the thumb of the same hand flexes.

Evidence Discussion (SP-7)

v3.0.2026

- MRI is the preferred imaging modality for evaluation of myelopathy. It provides superior soft tissue definition to other options and allows direct visualization of intramedullary cord signal changes which can affect prognosis and management.[10]
- CT Myelogram may be appropriate when MRI is contraindicated or for surgical planning. It may allow better visualization of bony neuroforaminal narrowing and may provide additional anatomic information when the MRI is ambiguous.[10,11]
- CT can be useful in demonstrating bony encroachment on the cord, but MRI is superior in demonstrating bone marrow changes and intramedullary cord signal. It is of limited value in evaluation of non-compressive causes of myelopathy.[10]

Spondylolysis (SP-8.1)

SP.SP.0008.1.A
v3.0.2026

Results of plain x-rays performed after the current episode of symptoms started or changed need to be available to the requesting provider, unless otherwise specified below.

Indication	Imaging Study
• Clinical suspicion of spondylolysis is high	• X-ray is not required • Tomographic SPECT Planar (CPT® 78803 or 78831) • SPECT/CT Hybrid (CPT® 78830 or 78832)
• Negative SPECT bone scan	MRI Lumbar Spine without contrast (CPT® 72148) **OR** CT Lumbar Spine without contrast (CPT®72131)
• Evaluation of a lesion seen on SPECT bone scan	CT Lumbar Spine without contrast (CPT® 72131)
• Documented need for preoperative planning	MRI Lumbar Spine without contrast (CPT® 72148) **AND/OR** CT Lumbar Spine without contrast (CPT®72131)
• Failure of 6 weeks of provider-directed conservative treatment (which may include immobilization with a spinal orthosis) after the current set of symptoms or physical exam findings started or changed with clinical re-evaluation	MRI Lumbar Spine without contrast (CPT® 72148) **OR** CT Lumbar Spine without contrast (CPT®72131)
• Evaluation for stress reaction in bone, to visualize nerve roots	MRI Lumbar Spine without contrast (CPT® 72148)
• When an MRI is medically necessary, however, it is contraindicated	CT Lumbar Spine without contrast (CPT®72131)

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Click Here to Return to the Main TOC

Indication	Imaging Study
• Evaluation of bony anatomy	CT Lumbar Spine without contrast (CPT®72131)
• Monitor healing of a pars interarticularis fracture that was determined to have healing potential on a prior CT (i.e., non-sclerotic lesion)	CT Lumbar Spine without contrast (CPT® 72131) of the symptomatic spinal level

- For pediatric spondylolysis, see: **Spondylolysis (PEDSP-2.4)** in the Pediatric and Special Populations Spine Imaging Guidelines
- Bony healing cannot be achieved non-surgically in an established well defined isthmic pars interarticularis defect whether it is developmental or the result of a pars interarticularis fracture non-union. Repeat advanced diagnostic imaging is not medically necessary in this setting.

Background and Supporting Information

- Spondylolysis is most often an incidental finding on plain x-rays, and advanced imaging is generally not medically necessary.
- MRI is not medically necessary in the early diagnosis of spondylolysis due to the potential for false negative results.

Proprietary Information of UnitedHealthcare.

Spondylolisthesis (SP-8.2)

SP.SP.0008.2.A
v3.0.2026

- CT Lumbar Spine without contrast (CPT® 72131) or MRI Lumbar Spine without contrast (CPT® 72148) can be considered after plain x-ray (results of plain x-rays performed after the current episode of symptoms started or changed need to be available to the requesting provider) for the following:
  - Failure of 6-week trial of provider-directed treatment after the current set of symptoms or physical exam findings started or changed and clinical re-evaluation (see also: **General Guidelines [SP-1.0]**); ***or***
  - Preoperative evaluation; ***or***
  - See: **Red Flag Indications (SP-1.2)**

Background and Supporting Information

- Stress reactions and stress fractures of the pars interarticularis are most common in athletes and others whose activities involve repetitive flexion/extension loading of the lumbar spine and may be acute or chronic and unilateral or bilateral. Pars interarticularis defects can be an incidental finding on plain x-rays and is frequently asymptomatic.
- Spondylolisthesis is the forward (anterolisthesis) or backward (retrolisthesis, usually not clinically significant) displacement of one vertebra in relation to an adjacent vertebra, most commonly at L4-5 and L5-S1, although other levels of the spine may be involved. Spondylolisthesis is often an incidental finding on plain x-ray and is frequently asymptomatic.

Evidence Discussion (SP-8)

v3.0.2026

Spondylolysis is a very common incidental finding on radiographs in the general population but majority will be asymptomatic.[7] Spondylolysis is one of the potential causes of back pain in gymnasts.[6] Symptomatic pars lesions are particularly a clinical problem in adolescent athletes.[7,8] Spondylolysis and spondylolisthesis are a common cause of low back pain especially in young athletes but is a less common cause of neurologic compromise.[4] Plain radiographs with particular views display the majority of defects.[5] MRI has sensitivity of 78% for detecting L4-L5 lumbar degenerative spondylolisthesis compared with 98% for lateral standing films.[3] MRI is less sensitive than CT for detecting pars defects but it is useful for evaluating bone marrow edema,nerve root compression, and stress reactions.[8]

Lumbar spondylolysis can heal with conservative treatment depending on the spinal level affected and stage of the defects. The site of defects in the pars, condition of contralateral pars, presence of spondylolisthesis, the degree of lumbar lordosis are among other factors significantly affecting union.[10]

Lumbar Spinal Stenosis (SP-9.1)

SP.ST.0009.1.A
v3.0.2026

- MRI Lumbar Spine without contrast (CPT® 72148) or CT Lumbar Spine without contrast (CPT® 72131) is medically necessary for those individuals with clinical suspicion of lumbar spinal stenosis if:
  - Failure of 6-week trial of provider-directed treatment after the current set of symptoms or physical exam findings started or changed and clinical re-evaluation (see also: **General Guidelines (SP-1.0)**); ***or***
  - Red Flag Indications (see: **Red Flag Indications (SP-1.2)**); ***or***
  - Severe symptoms of neurogenic claudication restricting normal activity or requiring the frequent use of narcotic analgesics
- A CT/Myelogram Lumbar Spine (CPT® 72132) may also be considered for individuals who have failed 6-weeks of provider-directed treatment if requested by the operating surgeon for surgical planning, especially for multi-level lumbar spinal stenosis.

Background and Supporting Information

Lumbar spinal stenosis refers to a decrease in the space available for the neural elements within the spinal canal that include spinal nerve roots and the cauda equina. It is usually a degenerative condition of the aging spine which can be asymptomatic or a common cause of buttock/low back and/or leg pain (neurogenic claudication) in this population. Neurogenic claudication is a common symptom of lumbar spinal stenosis that is aggravated by walking, especially down hills or stairs, with prolonged standing and is often relieved by sitting and bending forward. Neurogenic claudication should be differentiated from vascular claudication (leg/calf pain) that is often aggravated by walking and relieved fairly rapidly by stopping and rest. The differential diagnosis for lumbar spinal stenosis should include peripheral vascular disease, hip disorders, and peripheral neuropathy.

Evidence Discussion (SP-9)

v3.0.2026

A presumptive diagnosis of symptomatic lumbar stenosis can be made with the history and physical examination.[5] Imaging can help differentiate neurogenic claudication from vascular claudication. MRI or CT may confirm the presence of spinal stenosis. The American College of Radiology (ACR) Appropriateness Criteria for low back pain (revised 2021) states MRI may be helpful when there is low back pain with radiculopathy or signs of spinal stenosis.[1] Bony findings can be seen better on CT and soft-tissue lesions are more detectable on MRI.[1] In individuals with subacute or chronic low back pain with or without radiculopathy that is a surgical or intervention candidate with persisting symptoms after six weeks of conservative treatment, CT lumbar spine without IV contrast can also be used to assess facets and neural foramina and is equal to MRI for predicting significant spinal stenosis.[1] For those not responsive to conservative treatment, surgery should be considered. A prospective cohort study evaluating individual outcomes two years after spine surgery for spinal stenosis showed individuals had better outcomes than individuals who did not have surgery.[4]

Fibromyalgia (SP-10.3)

SP.DI.0010.3.A

v3.0.2026

- Advanced diagnostic imaging is not supported by the scientific evidence for the evaluation and treatment of fibromyalgia.

Background and Supporting Information

- Sacroiliitis can present with pain localized to the SI joint or referred pain to the buttock and/or posterior thigh without neurologic signs or symptoms. Affected individuals can often point to the SI joint as the pain source. Provocative and/or therapeutic SI joint anesthetic/corticosteroid injections can have diagnostic value.
- There is no evidence demonstrating that advanced diagnostic imaging substantiates changes to individual management decisions in individuals with proven SI joint disorders when visible on routine plain x-rays.
- MRI has shown inflammatory changes in the SI joints prior to visible x-ray changes in several studies. However, the ability of MRI to characterize inflammation in early ankylosing spondylitis, the ability of MRI to predict erosive changes, and the value of monitoring treatment effects using serial MRI studies remains controversial in adults.

Proprietary Information of UnitedHealthcare.

Evidence Discussion (SP-10)

v3.0.2026

For individuals with proven sacro-iliac joint disorders visible on routine plain x-rays, there is no evidence that advanced diagnostic imaging substantiates changes to individual management decisions.

X-rays are first line imaging for suspected inflammatory sacroiliitis but have a low sensitivity for detecting abnormalities in early disease, and x-ray findings may not be visible until several years after onset of symptoms.[12] SI Joint MRI is appropriate when X-ray is equivocal or non-diagnostic.[12] There is increase the diagnostic accuracy of MRI in sacroiliitis with use of contrast.[12] Contrast use benefits must be weighed against potential disadvantages of need for IV access, potential risk for nephrogenic systemic fibrosis or contrast reaction, and increased cost. If an individual is unable to undergo MRI, a non-contrast CT may be helpful as it has improved sensitivity over conventional radiography for detection of subtle erosions, although it lacks sensitivity for inflammatory changes of inflammatory sacroiliitis.[12]

With suspected inflammatory spondylitis, x-rays are useful to assess for structural changes of syndesmophytes, erosions, vertebral body squaring, and ankylosis.[9] When x-rays are non-diagnostic, MRI (without or with contrast) can demonstrate active inflammatory changes.[9] The value of monitoring treatment response using serial MRIs remains controversial and investigational in adults.

Plain x-rays are not required prior to advanced imaging in individuals with documented ankylosing spondylitis or DISH (diffuse idiopathic skeletal hyperostosis) and spine pain following trauma, due to high risk of spinal fractures even with low-energy trauma and the low specificity for fracture detection on x-ray in these individuals.[8]

Advanced diagnostic imaging is not supported by scientific evidence for the evaluation and treatment of fibromyalgia.

Spinal Compression Fractures (SP-11.1)

SP.FX.0011.1.A
v3.0.2026

Individuals with no history of malignancy

- MRI without contrast, CT without contrast, or whole-body bone scan (CPT® 78306), SPECT (CPT® 78803), or SPECT/CT (CPT® 78830) of the affected spinal region is medically necessary after plain x-ray evaluation ***and*** the location of the individual's spinal pain is concordant with the spinal x-rays for any **ONE** of the following:
  - X-rays reveal a new spinal compression fracture ***or***
  - X-rays are non-diagnostic and severe spinal pain persists for more than one week in an individual already predisposed to low energy/insufficiency fractures ***or***
  - The age of the spinal compression fracture deformity on plain x-ray is indeterminate ***or***
  - Surgical planning following known insufficiency spinal compression fractures in individuals who are candidates for kyphoplasty, vertebroplasty or other spine surgical procedures

Individuals with a history of malignancy

- For individuals with new symptomatic or asymptomatic vertebral compression fractures on radiographs, please refer to the cancer-specific guidelines within the General Oncology Imaging Guidelines for appropriate imaging studies.
- See also: **Red Flag Indications (SP-1.2)**

Background and Supporting Information

Insufficiency/low energy spinal compression fractures of the spine occur due to the lack of structural integrity to withstand physiologic loads and minor spinal trauma. Low bone mineral density is the primary etiology for most of these fractures but could also occur in the setting of other bone disease and medical conditions, in addition to neoplastic disease and infection. Sudden localized back pain, with or without trauma, is a typical presentation of insufficiency/low energy spinal compression fractures and can often be an incidental finding on plain x-rays and can be asymptomatic.

Evidence Discussion (SP-11)

v3.0.2026

The diagnosis of a spinal compression fracture may be suspected based on history and physical examination. Plain anteroposterior and lateral radiographs should be the initial imaging study obtained for a suspected compression fracture.[3,7]

For individuals (without a known malignancy) with a new symptomatic vertebral compression fracture identified on radiographs, MRI without contrast, CT without contrast, whole-body bone scan, SPECT or SPECT/CT is supported by the American College of Radiology (ACR) Appropriateness Criteria for Management of Vertebral Compression Fractures (revised 2022).[2] Advanced imaging can also be helpful for identifying a fracture that is not well visualized on plain films.[3,5]

It has been shown that bone marrow signal on MRI can help identify an acute fracture and distinguish ages of compression fractures.[8,9] Additionally, the benefits of advanced imaging prior to vertebral augmentation have been reported.[10,11,12]

Initial Imaging Pathway (SP-13.1)

SP.CD.0013.1.A

v3.0.2026

- MRI Cervical Spine without contrast or without and with contrast (CPT® 72141 or CPT® 72156) and MRI Thoracic Spine without contrast or without and with contrast (CPT® 72146 or CPT® 72157) is medically necessary when syringomyelia is suspected.
- Once a syrinx is identified by prior imaging, the following are medically necessary if not already performed:
  - MRI Brain without contrast (CPT® 70551) to evaluate for syringobulbia **AND**
  - MRI Cervical Spine without contrast or without and with contrast (CPT® 72141 or CPT® 72156) **AND**
  - MRI Thoracic Spine without contrast or without and with contrast (CPT® 72146 or CPT® 72157) **AND**
  - MRI Lumbar Spine without contrast or without and with contrast (CPT® 72148 or CPT® 72158) to define the lower most extent of the syrinx or to identify a skip lesion

Follow-up Imaging (SP-13.2)

SP.CD.0013.2.A
v3.0.2026

- MRI Cervical Spine without contrast (CPT® 72141) and MRI Brain without contrast (CPT® 70551) and/or MRI Thoracic Spine without contrast (CPT® 72146) are medically necessary in the following scenarios:
  - If there is a concern for malignancy, imaging can be performed without and with contrast
  - Annual imaging until non-progression of the syringomyelia is established
  - Following surgical treatment (including posterior fossa decompression)
  - Advanced diagnostic imaging every three years for life can be performed once non-progression of the syringomyelia is established
  - Repeat advanced diagnostic imaging is medically necessary when there is evidence of neurologic deterioration

Background and Supporting Information

Syringomyelia may begin to form in childhood but rarely becomes symptomatic before the adult years.

Spinal Deformities (e.g., Scoliosis/ Kyphosis) (SP-14.1)

SP.SC.0014.1.A

v3.0.2026

- MRI without contrast, MRI without and with contrast, or CT/Myelography if MRI is contraindicated of the affected spinal regions is medically necessary after plain x-rays (e.g., Cobb radiographs) of the affected spinal regions have been performed and results are available to the requesting provider:
  - For pre-operative evaluation; ***or***
  - For cases of congenital scoliosis and other atypical curves that may be associated with spinal canal/cord pathology such as tethered cord, syringomyelia, diastematomyelia, or tumors; ***or***
  - For cases of scoliosis and/or kyphosis when there are associated neurologic signs and symptoms on physical examination; ***or***
  - Scoliosis with a convex left thoracic curve due to a high association of a convex left thoracic curve with underlying spinal canal/cord pathology
- CT of the affected spinal regions (contrast as requested) is medically necessary in cases with a complex osseous deformity for pre-operative evaluation
- CT Angiography (CTA) or MR Angiography (MRA) is not medically necessary for pre-operative planning for initial anterior spinal surgery for surgical correction of spinal deformities

Proprietary Information of UnitedHealthcare.
Copyright ©2026 United HealthCare Services, Inc.

Revision Anterior Spinal Deformity Surgery (SP-14.2)

SP.SC.0014.2.A

v3.0.2026

- If requested by the operating surgeon, the following studies can be performed for pre-operative planning for revision of anterior thoracic or lumbar spinal surgery:
  - CTA Pelvis (CPT® 72191) **OR**
  - CTA Abdomen (CPT® 74175) **OR**
  - CTA Abdomen and Pelvis (CPT® 74174) **OR**
  - MRA Pelvis (CPT® 72198) and/or MRA Abdomen (CPT® 74185)

Background and Supporting Information

- Scoliosis is defined as a curvature of the spine in the coronal plane. Scoliosis can involve any or all levels of the spine but generally involves the thoracic and/or lumbar spine. Scoliosis initially occurs in the pediatric and adolescent population and persists throughout life. If scoliosis begins in adulthood, it is usually secondary to neurologic disorders (e.g., post-traumatic paralysis) or degenerative spondylosis. Sagittal plane spinal deformity (e.g., kyphosis, hyperlordosis) may be associated with scoliosis.

Evidence Discussion (SP-14)

v3.0.2026

Plain radiography continues to be the primary imaging modality for the initial diagnosis of spinal deformity and for follow up of deformity progression.[13,14] Plain x-rays allow the easy measurement of Cobb angles which remains essential in the evaluation of scoliosis.[13]

Individuals with congenital scoliosis, atypical curves (for example, left thoracic) or abnormal neurological findings will benefit from MRI to help identify spinal cord abnormalities.[13,15,16,17] CT is considered the gold standard for the evaluation of osseous structures and can be useful in the evaluation of complex bony deformity.[13] Additionally, MRI and CT can be valuable for pre-operative evaluation.[18,19,20]

For revision anterior spinal deformity surgery, CT angiography or MR angiography may be medically necessary, however, concerns associated with these modalities are radiation exposure (CT), availability of the imaging modalities in close proximity to individuals, potential out of pocket costs to individuals and sensitivity to individual movement (MRI).[11,21]

Evidence Discussion (SP-15)

v3.0.2026

Despite advances made in high-resolution spinal imaging, plain films remain integral in providing optimal care for spine individuals and continue to provide critical information that cannot be obtained with other imaging modalities.[6] X-ray imaging with anteroposterior, lateral, oblique, and flexion-extension views is considered the primary imaging modality for post-operative evaluation and can provide complementary information to advanced imaging.[1,7] X-rays can provide information as to whether a concomitant instability is present which would further assist with pre-operative planning. Also, when prior surgery is a concern, x-ray provides additional clinical information as to the details of the hardware for which this detail can many times be obscured with advanced imaging techniques (MRI/CT). An x-ray often has a larger field-of-view than an MRI or CT and has the potential to identify more proximal or distal pathology in the spine that could ultimately assist in determining the individual's diagnosis.[6] X-rays can also determine whether an advanced diagnostic imaging study is actually needed, what specific advanced diagnostic imaging study is warranted and if contrast is required.

There are risks associated with advanced imaging including but not limited to radiation exposure, implanted device complications, metallic foreign body complications and contrast complications.[10] Studies have also linked the increase rate of imaging with the increase rate of surgery and also found early magnetic resonance imaging (MRI) had an eightfold increased risk of surgery.[11,12]

Although most individuals with acute neck or back pain will improve with 6 weeks of conservative care[7,8,9], conservative care would not be necessary for individuals with prolonged intractable pain present within 6 months of surgery or if a red flag indication was present. In general, initial plain x-rays and an initial course of conservative care can provide a significant clinical benefit that would outweigh the clinical harm from perhaps briefly delaying advanced imaging if needed. A course of conservative care or plain x-ray findings many times may obviate the need for advanced imaging which possess their own set of significant risks.

For revision thoracic or lumbar anterior spinal arthrodesis, CT angiography or MR angiography may be medically necessary, however, risks are present with these modalities including radiation exposure (CT), availability of the imaging modalities in close proximity to individuals, potential out-of-pocket costs to individuals, and sensitivity to individual movement (MRI).[5,10]

v3.0.2026

- Advanced diagnostic imaging studies of the spine are not required prior to facet joint injections, medial branch blocks or radiofrequency ablations unless the criteria for advanced imaging studies of the spine are met as otherwise stated in the Spine Imaging Guidelines.
- Advanced diagnostic imaging studies of the cervical spine and/or thoracic spine are medically necessary within 24 months prior to interlaminar or transforaminal epidural steroid injections of the cervical and/or thoracic spine when the criteria for advanced imaging studies of the spine are met as otherwise stated in the Spine Imaging Guidelines.
- Advanced diagnostic imaging studies of the lumbar spine are medically necessary prior to transforaminal epidural steroid injections of the lumbar spine when the criteria for advanced imaging studies of the spine are met as otherwise stated in the Spine Imaging Guidelines.
- Advanced diagnostic imaging studies of the lumbar spine are not required prior to lumbar spine interlaminar or caudal epidural steroid injections unless the criteria for advanced imaging studies of the spine are met as otherwise stated in the Spine Imaging Guidelines.
- For an individual with evidence of symptomatic spinal stenosis, MRI or CT with or without myelography demonstrating severe spinal stenosis at the level to be treated within the past 24 months is required for an initial trial of a transforaminal, interlaminar or caudal epidural steroid injection when **ALL** of the following criteria are met:
  - Diagnostic evaluation has ruled out other potential causes of pain
  - Significant functional limitations resulting in diminished quality of life and impaired age-appropriate activities of daily living (ADLs)
  - Failure of at least 4 weeks of conservative treatment (e.g., exercise, physical methods including physical therapy and/or chiropractic care, NSAIDs, and/or muscle relaxants)
- See: **Red Flag Indications (SP-1.2)** for severe radicular pain

Prior to Spinal Cord Stimulator (SCS) Placement/Removal (SP-16.3)

SP.OI.0016.3.A

v3.0.2026

- MRI Thoracic Spine without contrast (CPT® 72146) is generally the study of choice prior to SCS placement. CT Thoracic Spine without contrast (CPT® 72128) **OR** CT/ Myelography Thoracic Spine (CPT® 72129) are acceptable alternatives.
- Imaging of the lumbar spine is not medically necessary for placement nor removal of spinal cord stimulators.

Following Vertebral Augmentation Procedures (SP-16.4)

SP.OI.0016.4.A

v3.0.2026

- CT without contrast of the affected spinal region(s) within 24 hours post-procedure to evaluate neurologic sequelae resulting from cement extravasation

Background and Supporting Information

- MRI has not been shown to change the outcome of interventional pain procedures in recent scientific evidence-based studies and without substantial change in the clinical picture or intervening surgery. Repeat advanced diagnostic imaging studies are not necessary with each spinal injection or series of spinal injections.

Evidence Discussion (SP-16)

v3.0.2026

- Advanced imaging needed for surgical planning (e.g., MRI and/or CT) should be performed for pre-operative planning prior to spine surgery.[9,10] MRA and CTA are generally not medically necessary for pre-operative planning of initial anterior spinal surgery unless abnormal vasculature is known or reasonably anticipated.
- Advanced diagnostic imaging studies of the spine are not required prior to facet joint injections, medial branch blocks or radiofrequency ablations unless the criteria for advanced imaging studies of the spine are met as otherwise stated in the Spine Imaging Guidelines.[5,7]
- MRI Thoracic Spine without contrast is generally the study of choice prior to SCS placement, however, CT Thoracic Spine without contrast or CT/ Myelography Thoracic Spine are acceptable alternatives. Imaging of the lumbar spine is not medically necessary for placement nor removal of spinal cord stimulators.[11]
- CT without contrast of the affected spinal region(s) within 24 hours post-procedure to evaluate neurologic sequelae resulting from cement extravasation.[12]

Nuclear Medicine (SP-17)

SP.FX.0017.A
v3.0.2026

- For evaluation of suspected loosening of orthopedic implants, when recent plain x-ray is non-diagnostic:
  - Bone scan (CPT® 78315) **OR**
  - Distribution of Radiopharmaceutical Agent SPECT (CPT® 78803, or 78831) **OR**
  - SPECT/CT (CPT® 78830)
- Back pain with suspected failed fusion surgery, with suspected painful pseudoarthrosis and MRI/CT are non-diagnostic:
  - Radiopharmaceutical Localization SPECT (CPT® 78803, or 78831) **OR**
  - SPECT/CT (CPT® 78830)
- Any of the following studies are medically necessary for initial evaluation of suspected spine osteomyelitis and for follow-up imaging for evaluation of response to treatment in established spine osteomyelitis:
  - 3-phase bone scan (CPT® 78315) of the spine **OR**
  - Bone SPECT (CPT® 78803 or 78831) or Bone SPECT/CT (CPT® 78830 or 78832) **OR**
    - SPECT CPT® codes include flow and blood pool and delayed SPECT imaging
  - Gallium scan whole-body (CPT® 78804) or Limited spine (CPT® 78801) **OR**
  - Gallium SPECT (CPT® 78803 or 78831) or SPECT/CT (CPT® 78830 or 78832) **OR**
  - Gallium scan whole-body (CPT® 78804) or Limited spine (CPT® 78801) with SPECT (CPT® 78803 or 78831) or SPECT/CT (CPT® 78830 or 78832)
  - **NOTE:** Any bone scan can be combined with any Gallium scan
- Suspected spine infection (such as epidural abscess or discitis osteomyelitis) next imaging study
  - FDG-PET/CT whole-body when x-ray or CT are abnormal **AND** when MRI cannot be performed or is inconclusive[7]
- For evaluation of facet arthropathy in individuals with ankylosing spondylitis, osteoarthritis, or rheumatoid arthritis:
  - Radiopharmaceutical Localization Inflammatory Imaging (one of CPT® codes: 78800, 78801, 78802, or 78803) **OR**
  - Distribution of Radiopharmaceutical Agent SPECT (CPT® 78803) **OR**
  - SPECT/CT (CPT® 78830)
- For the evaluation of back pain and suspected spondylolysis:
  - Radiopharmaceutical Agent SPECT (CPT® 78803 or 78831) **OR**
  - SPECT/CT (CPT® 78830 or 78832)

Evidence Discussion (SP-17)

v3.0.2026

The American College of Radiology (ACR) Appropriateness Criteria for low back pain (revised 2021)[1] states that CT or MRI imaging may be considered for individuals with spinal issues who have had failed at least 6 weeks of medical management or physical therapy. For most individuals with spine issues, MRI and or CT is the study of choice after failed conservative treatments. There is no relevant literature to support the use of bone scan with single-photon emission CT (SPECT) or SPECT/CT in the initial evaluation of acute uncomplicated LBP.

Given the risk of radiation from nuclear medicine imaging it is important to carefully select the proper individual indication. Based on ACR Appropriateness Criteria for low back pain (revised 2021) and also supported by literature, nuclear medicine is used infrequently but is supported for the following indication:

- Structures with abnormal morphology on conventional imaging may not be the cause of LBP. Evidence suggests possible utility of bone scan with SPECT or SPECT/CT as a functional modality to localize the source of LBP, particularly for facet arthropathy.[5]
- SPECT bone scan is the reference standard for detection of radiographically occult active spondylolysis in the young individual.[6]
- Bone scan with SPECT/CT is usually not used for initial imaging but can be useful for radiographically occult fractures and can be used to evaluate acuity of vertebral fracture.
- Bone scan can be used for suspected loosening of orthopedic implants and failed fusion surgery when recent plain x-ray is non-diagnostic. MRI evaluation of these individuals can be significantly limited due to metal artifact from the implants.
- Bone scan and whole-body bone scintigraphy labeled scans can be used for suspected spinal osteomyelitis.

Chronic limb swelling due to venous insufficiency/Venous stasis changes/ Varicose veins (PVD-14)

PVD.VI.0014.A
v2.0.2026

Venous Reflux (PVD-14.2)

- A venous valvular insufficiency study (CPT® 93970 bilateral study or CPT® 93971 unilateral study) is medically necessary to diagnose presence of reflux in the greater saphenous vein as well as the size of the refluxing vein.
- A duplex ultrasound (CPT® 93970 bilateral study or CPT® 93971 unilateral study) is medically necessary within six months before treatment with intervention to demonstrate the presence of pathologic reflux (>500ms) within the greater and lesser saphenous veins and document vein size.
- A post-ablation venous ultrasound (CPT® 93970 bilateral study or CPT® 93971 unilateral study) is medically necessary within seven days post-procedure.
  - If thrombus is noted within the saphenofemoral junction, repeat imaging can be performed within seven days to assess for propagation into the deep system.
- Post-procedure assessment by imaging techniques is not medically necessary to confirm efficacy or outcome of the procedure.

Evidence Discussion

Venous insufficiency–– General information

- Venous insufficiency is characterized by failure of the venous blood to flow in its normal path of flow and instead refluxes backwards by the force of gravity usually secondary to malfunction of the venous valves.
- Risk factors include previous DVT, obesity, hereditary, and environmental factors such as prolonged standing on a hard surface.
- Venous insufficiency loosely includes the diagnosis of venous reflux, varicose veins, venous stasis ulcers and spider/reticular veins.
- Diagnosis is made with a venous valvular insufficiency study which documents the presence of reflux (>500ms) in the greater saphenous vein as well as the size of the refluxing vein (3-15mm).
- Treatment of superficial venous reflux is amenable to intervention in selected individuals who are symptomatic and have failed conservative therapy.
